

THE
DISPENSATORY
OF THE
UNITED STATES OF AMERICA

BY
DR. GEO. B. WOOD AND DR. FRANKLIN BACHE.

NINETEENTH EDITION.
THOROUGHLY REVISED, LARGELY REWRITTEN, AND BASED UPON THE EIGHTH DECENNIAL
REVISION OF THE UNITED STATES PHARMACOPOEIA.

BY
H. C. WOOD, M.D., LL.D.,
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE UNIVERSITY OF PENNSYLVANIA; PRESIDENT OF THE
CONVENTION OF 1900 FOR THE REVISION OF THE PHARMACOPOEIA OF THE UNITED STATES;
MEMBER OF THE NATIONAL ACADEMY OF SCIENCE,

JOSEPH P. REMINGTON, PH.M., F.C.S.,
PROFESSOR OF THEORY AND PRACTICE OF PHARMACY IN THE PHILADELPHIA COLLEGE OF PHARMACY; CHAIRMAN OF THE
COMMITTEE OF REVISION OF THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA,

AND
SAMUEL P. SADTLER, PH.D., LL.D.,
PROFESSOR OF CHEMISTRY IN THE PHILADELPHIA COLLEGE OF PHARMACY; MEMBER OF THE COMMITTEE OF REVISION OF
THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA,

ASSISTED BY
ALBERT B. LYONS, M.D.,
MEMBER OF THE COMMITTEE OF REVISION OF THE PHARMACOPOEIA OF THE UNITED STATES OF AMERICA,

AND
HORATIO C. WOOD, JR., M.D.,
DEMONSTRATOR OF PHARMACODYNAMICS IN THE UNIVERSITY OF PENNSYLVANIA.

PHILADELPHIA
J. B. LIPPINCOTT COMPANY

Entered, according to Act of Congress, in the year 1877,
By GEORGE B. WOOD, M.D.,
In the Office of the Librarian of Congress at Washington.

Authority to use for comment the Pharmacopœia of the United States of America, Eighth Decennial Revision, in this volume, has been granted by the Board of Trustees of the United States Pharmacopœial Convention, which Board of Trustees is in no way responsible for the accuracy of any translation of the official weights and measures or for any statements as to strength of official preparations. Alternative quantitles are put in square brackets [] and an asterisk (*) added to each official formula. The asterisk in the text of this volume has been used in accordance with the direction of the Board of Trustees.

Permission to use for comment parts of the text of the National Formulary has been granted by the Council of the American Pharmaceutical Association.

PREFACE TO THE NINETEENTH EDITION.

THE Nineteenth Edition of the United States Dispensatory is issued at a time in American history when the public mind has been thoroughly aroused to the necessity of demanding purity in drugs and honesty in purveying them. The future is therefore crowded with possibilities of the greatest advance in medicine and pharmacy that has occurred within a century of progress. In 1833 the authors of this work placed before the professions the result of their labors, stating in their preface that "it is desirable that there should be a Dispensatory of the United States, which, while it embraces all that is useful in European pharmacy, may accurately represent the art as it may exist in this country and give instruction adapted to our peculiar wants." That "they builded wiser than they knew" is now a matter of history, for the work has grown to be a standard authority as it enters upon its 74th year of existence.

For the first time in the history of the United States our National Government has adopted the United States Pharmacopœia as a standard, and this work, which has for nearly ninety years relied upon its merit for general acceptance, has at last received *full legal recognition*.

The editors of the Dispensatory, appreciating their increased responsibility, determined to institute some radical changes and improvements, which they sincerely trust will meet with the approval of the many readers of the book. The change which will first attract attention is the use of the double column throughout the text. The great increase in the number of "new remedies" in the last twenty years and the necessity for limiting the size of the book presented a problem which was not easy to solve to the satisfaction of the editors. By widening the pages of the Seventeenth and Eighteenth Editions their number was diminished, but the difficulty experienced by the reader, when consulting the pages, in quickly reading the following line, was recognized, and inasmuch as the work had in seventy-four years advanced to the importance of an encyclopedia, it was decided to change the style of the old book and use the double column. This has been done without sacrificing any of the features which have been recognized as valuable in the previous editions.

The introduction of synonyms of the drugs and preparations has been continued and the number increased, but it should be remembered, in consulting these, that they do not usually represent equivalent preparations; they are inserted for the information of the reader, to indicate drugs and preparations of greater or less similarity to those represented by the titles, and they are in no case intended to be construed as legal equivalents.

A new feature in this edition is the insertion at the end of the articles of a list of the preparations which are official in the United States and British Pharmacopœias. It is believed that these will be of service by indicating to the physician the preparations of a drug which are available for his use in prescribing, and to familiarize all with the unabbreviated official titles, which have been grouped alphabetically.

Quantities are indicated, as heretofore, in the metric system, and it was confidently hoped that by this time the metric system would have made so much progress in this country that the use of the alternative formulas expressed in old-form terms could be discontinued. These were first used in this work in 1883, and since then the method has been adopted by the British Pharmacopœia and the National Formulary. Until the use of the metric system is made compulsory by legal enactment, it would seem to be necessary to express quantities in both systems. It should be remembered, however, that the metric and old-form quantities are not interchangeable, and in using the formulas in the book either the metric quantities must be used exclusively, or the old-form quantities alone.

The custom which has been so long established in revising this work, of citing "journal references" to the abstracts and comments, has been continued, because it enables a reader to consult an article *in extenso* from the journal or book, when he finds the abstract insufficient for his needs. To save space, a system of abbreviation is used, and a table explaining the abbreviation and giving the name of the journal in full will be found in the preliminary pages. A glance at the table will show that this feature has been greatly enlarged in the Nineteenth Edition, as there are 185 titles compared with 54 in the previous one.

An asterisk preceding each preparation of the United States Pharmacopœia, Eighth Revision, followed by alternative quantities in brackets, indicates that the United States Pharmacopœia is not responsible for the correctness of these quantities, because, as is well known, the metric system is used exclusively in the latter book.

While the Board of Trustees of the United States Pharmacopœial Convention have permitted commentaries and text-books to use the text of the Pharmacopœia upon payment of a money consideration, the American Pharmaceutical Association resolved to withhold permission from any books to use the full text of the National Formulary. They have, however, permitted the use of a part of the text of this book, which will be found in Part III, Section II, with comments.

The pronunciation of the official titles is indicated, as heretofore, by the use of diacritical marks. This feature has commended itself to students and teachers, and it is an assistance in rendering the pronunciation of the Latin titles more uniform throughout the country.

Part II, as in the previous edition, is devoted to unofficial drugs, and the custom of using smaller type serves a useful purpose by differentiating official from unofficial substances. It also permits more extended comments than would otherwise be possible, as the saving of space must constantly be kept in mind.

The Food and Drugs Act with Rules and Regulations is printed in full in the preliminary pages with the object of placing this in a permanent form for easy reference.

The editorial staff remains unchanged since the Fifteenth Edition was published in 1883. Professor H. C. Wood has, as heretofore, revised the botany and materia medica, with the uses of the drugs and preparations; Professor Joseph P. Remington has had charge of the pharmacy and pharmaceutical chemistry of the work; and Professor Samuel P. Sadtler has revised the theoretical chemistry and toxicology. But at the outset of the revision of this edition it was realized that assistance should be secured, and the editors were fortunate in obtaining the services of Dr. Albert B. Lyons of Detroit, and Dr. Horatio C. Wood, Jr., of Philadelphia. The former is well known as an author on chemical and botanical subjects, and his excellent work on the assay of alkaloidal drugs is widely known and appreciated. Dr. H. C. Wood, Jr., has prepared the index of diseases, and the thanks of the editors are due to both of these gentlemen for the careful revision of the proof-sheets of the work. To M. J. Rosenau, M.D., Director of the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service, who contributed the article on Serum Antidiphthericum, especial thanks are extended. Acknowledgements are also due to M. S. Renshaw and Prof. E. Fullerton Cook, for their assistance in proof reading, and to the latter has fallen the task of preparing the enlarged index.

The Nineteenth Edition is issued from entirely new plates, and it is confidently believed that the new dress will be acceptable to all of its readers. More labor and greater care have been expended upon this edition than upon any previous one. The enactment of the Food and Drugs Law has awakened, to a greater extent than ever before in this country, an interest in authoritative books, and the editors, while sensible of many shortcomings, sincerely hope that this edition will prove a most worthy successor to those which have preceded it, and they trust that the book will merit the approbation which has been so freely granted to its predecessors.

PREFACE TO THE FIRST EDITION.

THE objects of a Dispensatory are to present an account of medicinal substances in the state in which they are brought into the shops, and to teach the modes in which they are prepared for use. The importance of these objects, and the general value and even necessity of a work of this nature, will not be disputed. It may, however, be a question, how far the wants of the medical and pharmaceutical community in this country are supplied by the Dispensatories already in circulation; and whether such a deficiency exists as to justify the offer of a new one to the public attention. The great merits of the works severally entitled "The Edinburgh New Dispensatory" and "The London Dispensatory," the former edited by the late Andrew Duncan, M.D., the latter by Anthony Todd Thomson, M.D., are well known wherever the English language is spoken. Founded, as they both are, upon the excellent basis laid by Lewis, they are nevertheless entitled, from the great addition of valuable materials, and the distinctive character exhibited in the arrangement of these materials, to be considered as original works; while the style in which they have been executed speaks strongly in favor of the skill and industry of their authors. But they were calculated especially for the sphere of Great Britain, and are too deficient in all that relates exclusively to this country, to admit of being received as standards here. In the history of our commerce in drugs, and of the nature, growth, and collection of our indigenous medical plants; in the chemical operations of our extensive laboratories; and in the modes of preparing, dispensing, and applying medicines, which have gradually grown into use among us; there is much that is peculiar, a knowledge of which is not to be gained from foreign books, and is yet necessary to the character of an accomplished American pharmacist. We have, moreover, a National Pharmacopœia, which requires an explanatory commentary, in order that its precepts may be fully appreciated, and advantageously put into practice. On these accounts, it is desirable that there should be a Dispensatory of the United States, which, while it embraces whatever is useful in European pharmacy, may accurately represent the art as it exists in this country, and give instruction adapted to our peculiar wants. It appears due to our national character that such a work should be in good faith an American work, newly prepared in all its parts, and not a mere edition of one of the European Dispensatories, with here and there additions and alterations, which, though they may be useful in themselves, cannot be made to harmonize with the other materials so as to give to the whole an appearance of unity, and certainly would not justify the assumption of a new national title for the book. Whether, in the Dispensatories which have been published in the United States, these requisites have been satisfactorily fulfilled, it rests with the public to determine. That valuable treatises on *Materia Medica* and Pharmacy have been issued in this country, no candid person, acquainted with our medical literature, will be disposed to deny. In offering a new work to the medical and pharmaceutical professions, the authors do not wish to be considered as undervaluing the labors of their predecessors. They simply conceive that the field has not been so fully occupied as to exclude all competition. The Pharmacy of continental Europe is ground which has been almost untouched; and much information in relation to the natural history, commerce, and management of our own drugs, has lain ungathered in the possession of individuals, or scattered in separate treatises and periodicals not generally known and read. Since the publication of the last edition of our National Pharmacopœia, no general explanation of its processes has appeared, though required in justice both to that work and to the public. The hope of being able to supply these deficiencies may, perhaps, be considered a sufficient justification for the present undertaking.

The Pharmacopœia of the United States has been adopted as the basis of this Dispensatory. It is followed both in its general division of medicines, and in its alphabetical arrangement of them under each division. Precedence is, in every instance, given to the names it recognizes, while the explanations by which it fixes the significance of these names are inserted in immediate connection with the titles to which they severally belong. Every article which it designates is more or less fully described; and all its processes, after being literally copied, are commented on and explained wherever comment and explanation appeared necessary. Nothing, in fine, has been omitted, which, in the estimation of the authors, could serve to illustrate its meaning, or promote the ends which it was intended to subserve. This course of proceeding appeared to be due to the national character of the Pharmacopœia, and to the important object of establishing, as far as possible, throughout the United States, uniformity, both in the nomenclature and preparation of medicines. In one particular, convenience required that the plan of the Pharmacopœia should be departed from. The medicines belonging to the department of MATERIA MEDICA, instead of being arranged in two divisions corresponding with the *Primary and Secondary Catalogues* of that work, have been treated of indiscriminately in alphabetical succession; and the place which they respectively hold in the Pharmacopœia is indicated by the employment of the term *Secondary*, in connection with the name of each of the medicines included in the latter catalogue.

But, though precedence has thus been given to the Pharmacopœia of the United States, those of Great Britain have not been neglected. The nomenclature adopted by the different British Colleges, and their formulas for the preparation of medicines, have been so extensively followed throughout the United States, that a work intended to represent the present state of pharmacy in this country would be imperfect without them; and the fact that the writings of British physicians and surgeons, in which their own official terms and preparations are exclusively employed and referred to, have an extensive circulation among us, renders some commentary necessary in order to prevent serious mistakes. The Pharmacopœias of London, Edinburgh, and Dublin have, therefore, been incorporated, in all their essential parts, into the present work. Their official titles are uniformly given, always in subordination to those of the United States Pharmacopœia, when they express the same object; but in chief, when, as often happens, no corresponding medicine or preparation is recognized by our national standard. In the latter case, if different names are applied by different British Colleges to the same object, that one is generally preferred which is most in accordance with our own system of nomenclature, and the others are given as synonymes. The medicines directed by the British Colleges are all described, and their processes either copied at length, or so far explained as to be intelligible in all essential particulars.

Besides the medicinal substances recognized as official by the Pharmacopœias alluded to, some others have been described, which, either from the lingering remains of former reputation, from recent reports in their favor, or from their important relation to medicines in general use, appear to have claims upon the attention of the physician and apothecary. Opportunity has, moreover, been taken to introduce incidentally brief accounts of substances used in other countries or in former times, and occasionally noticed in medical books; and, that the reader may be able to refer to them when desirous of information, their names have been placed with those of the standard remedies in the Index.

In the description of each medicine, if derived immediately from the animal, vegetable, or mineral kingdom, the attention of the authors has been directed to its natural history, the place of its growth or production, the method of collecting and preparing it for market, its commercial history, the state in which it reaches us, its sensible properties, its chemical composition and relations, the changes which it undergoes by time and exposure, its accidental or fraudulent adulterations, its medical properties and application, its economical uses, and the pharmaceutical treatment to which it is subjected. If a

chemical preparation, the mode and principles of its manufacture are indicated in addition to the other particulars. If a poison, and likely to be accidentally taken, or purposely employed as such, its peculiar toxicological effects, together with the mode of counteracting them, are indicated; and the best means of detecting its presence by reagents are explained.

The authors have followed the example of Dr. A. T. Thomson, in giving botanical descriptions of the plants from which the medicines treated of are derived. In relation to all indigenous medicinal plants, and those naturalized or cultivated in this country, the advantages of such descriptions are obvious. The physician may often be placed in situations in which it may be highly important that he should be able to recognize the vegetable which yields a particular medicine; and the apothecary is constantly liable to imposition from the collectors of herbs, unless possessed of the means of distinguishing, by infallible marks, the various products presented to him. A knowledge of foreign medicinal plants, though of less importance, will be found useful in various ways, independently of the gratification afforded by the indulgence of a liberal curiosity in relation to objects so closely connected with our daily pursuits. The introduction of these botanical notices into a Dispensatory appears to be peculiarly appropriate; as they are to be considered rather as objects for occasional reference than for regular study or continuous perusal, and therefore coincide with the general design of the work, which is to collect into a convenient form for consultation all that is practically important in relation to medicines. The authors have endeavored to preserve a due proportion between the minuteness of the descriptions, and their value as means of information to the student; and, in pursuance of this plan, have generally dwelt more at length upon our native plants than upon those of foreign growth; but, in all instances in which they have deemed a botanical description necessary, they have taken care to include in it the essential scientific character of the genus and species, with a reference to the position of the plant in the artificial and natural systems of classification; so that a person acquainted with the elements of botany may be able to recognize it when it comes under his observation.

In preparing the Dispensatory, the authors have consulted, in addition to many of the older works of authority, the greater number of the treatises and dissertations which have recently appeared upon the various subjects connected with Pharmacy, and especially those of the French writers, who stand at present at the head of this department of medical science. They have also endeavored to collect such detached facts, scattered through the various scientific, medical, and pharmaceutical journals, as they conceive to be important in themselves, and applicable to the subjects under consideration; and have had frequent recourse to the reports of travellers in relation to the natural and commercial history of foreign drugs. The occasional references in the body of the work will indicate the sources from which they have most largely drawn, and the authorities upon which they have most relied. In relation to our own commerce in drugs, and to the operations of our chemical laboratories, they are indebted for information chiefly to the kindness of gentlemen engaged in these branches of business, who have always evinced, in answering their numerous inquiries, a promptitude and politeness which merit their warm thanks, and which they are pleased to have this opportunity of acknowledging.¹

It has not been deemed necessary to follow the example of the British Dispensatories, by inserting into the work a treatise upon chemistry, under the name of Elements of

¹ The authors deem it proper to state that they are peculiarly indebted for assistance to Mr. Daniel B. Smith, president of the Philadelphia College of Pharmacy, to whom, besides much important information in relation to the various branches of the apothecary's business, they owe the prelatory remarks on Pharmacy, which are placed at the commencement of the second part of the work, and the several articles, in the *Materia Medica*, upon *Leeches*, *Carbonate of Magnesia*, and *Sulphate of Magnesia*.

Pharmacy. Such a treatise must necessarily be very meagre and imperfect, and, as systems of chemistry are in the hands of every physician and apothecary, would uselessly occupy the place of valuable matter of less easy access.

The authors may, perhaps, be permitted to observe, in relation to themselves, that they have expended much time and labor in the preparation of the work; have sought diligently for facts from every readily accessible source; have endeavored, by a comparison of authorities, and a close scrutiny of evidence, to ascertain the truth whenever practicable; and have exerted themselves to the extent of their abilities to render the Dispensatory worthy of public approbation, both for the quality and quantity of its contents, and the general accuracy of its statements. They are conscious, nevertheless, that in so great a multiplicity of details, numerous errors and deficiencies may exist, and that the faults of undue brevity in some cases, and prolixity in others, may not have been entirely avoided; but they venture to hope that a candid public will make all due allowances; and they take the liberty to invite, from all those who may feel interested in the diffusion of sound pharmaceutical knowledge, the communication of friendly suggestions or criticisms in relation to the objects and execution of the work.

EXPLANATORY KEY TO THE PRONUNCIATION.

The introduction of diacritical marks to indicate the pronunciation of the official titles in this work requires the insertion of a key to make them intelligible. The system in use in Worcester's Dictionary has been adopted.

- ä..long, as in fäte.
 ä..short, as in fät.
 ʒ..obscure, as in ʒide.
 ʌ..long before r, as in färe.
 ʌ..Italian or grave, as in fär.
 ʌ..intermediate, as in fäst.
 ʌ..broad, as in fäll.

- ē..long, as in mēte.
 ē..short, as in mēt.
 ẹ..obscure, as in othẹr.
 ẹ..like ʌ, as in hẹir.
 ẹ..obtuse, as in hẹr.
 (b)

- ī..long, as in pine.
 ī..short, as in pin.
 j..obscure, as in perjł.
 i..like long ē, as in mien.
 i..obtuse, as in sīr.

- ö..long, as höpe.
 ö..short, as in nôt.
 ɔ..obscure, as in arbɔr.
 ô..long and close, as in mōve.
 ȳ..broad, as in nȳr.
 ȳ..like short ū, as in sȳn.

- ū..long, as in tūbe.
 ū..short, as in büt.
 ʋ..obscure, as in suppose.
 ũ..as in annual.
 ũ..short and obtuse, as in bŭr.
 ŭ..long and close, as in rŭle.

- ç..soft, like s.
 ƣ..hard, like k.
 ǵ..like j.
 ʒ..like z.
 ʝ..like i.

GLOSSARY.

IN the following Glossary will be found short definitions of many of the terms employed in the Dispensatory to designate the medical properties of the remedies; most of the words are commonly employed as nouns, and sometimes as adjectives.

Absorbents.—Drugs used to produce absorption of exudates or diseased tissues.

Abstergents.—Detergents.

Alteratives.—Medicines used to so modify nutrition as to overcome morbid processes.

Anæsthetics.—Medicines used to produce anæsthesia or unconsciousness.

Analeptics.—Restorative medicines, or food.

Analgesics.—Medicines used to allay pain.

Anaphrodisiacs.—Medicines used to allay sexual feeling.

Anodynes.—Medicines used to allay pain.

Antacids.—Medicines used to neutralize acid in the stomach and intestines.

Anthelmintics.—Medicines used to destroy intestinal worms.

Antiarthritics.—Medicines used for the relief of gout.

Antihydropsics.—Medicines used for the relief of dropsy.

Antilithics.—Medicines used for the relief of calculous affections.

Antiperiodics.—Medicines used for the relief of malarial fevers.

Antipyretics.—Medicines used for the reduction of bodily temperature in fevers.

Antiseptics.—Substances which have the power of preventing putrefaction.

Antispasmodics.—Medicines used for the relief of nervous irritability and minor spasms.

Antisyphilitics.—Medicines used for the relief of syphilis.

Antizymotics.—Substances which have the power of killing disease-germs.

Aperients.—Mild purgatives.

Aphrodisiacs.—Substances used to increase sexual power or excitement.

Aromatics.—Medicines characterized by a fragrant or spicy taste and odor, and stimulant to the gastrointestinal mucous membrane.

Aromatic Bitters.—Medicines which unite the properties of the aromatics and the simple bitters.

Astringents.—Medicines having the power of influencing vital contractility, thereby condensing tissues.

Bitters—Simple.—Medicines which have a bitter taste and have the power of stimulating the gastrointestinal mucous membrane, without affecting the general system.

Blisters.—Medicines which when locally applied cause inflammatory exudation of serum from the skin, and are used as revulsants.

Calefacients.—Medicines used externally to cause a sense of warmth.

Cardiac Depressants.—Medicines used to lower the heart's action.

Cardiac Stimulants.—Medicines used to increase the heart's action.

Carminatives.—Medicines containing a volatile oil used to excite intestinal peristalsis and provoke an expulsion of flatus.

Cathartics.—Purgatives.

Caustics.—Medicines used to destroy living tissues.

Cholagogues.—Medicines which provoke a flow of bile.

Constringents.—Astringents.

Convulsants.—Medicines which cause convulsions.

Correctives.—Medicines used to correct or render more pleasant the action of other remedies, especially purgatives.

Corrigents.—Correctives.

Demulcents.—Mucilaginous principles which are used in solution to soothe and protect irritated mucous membranes or other tissues.

Deobstruents.—(Term obsolete and not very definite.) Medicines which overcome obstruction; aperients.

Deodorants.—Substances which destroy or hide foul odors.

Depilatories.—Substances used to remove hair.

Depressants.—Sedatives.

Depresso-Motors.—Medicines which lessen motor activity.

Depurants.—Medicines which act upon the emunctories so as to cause excretion and thereby purify the system.

- Detergents.**—Medicines which cleanse wounds, ulcers, etc.
- Diaphoretics.**—Medicines which produce sweating.
- Digestants.**—Ferments and acids which have the power of aiding in the solution of food.
- Diluents.**—Medicines which dilute secretions and excretions.
- Disinfectants.**—Substances which have the power of destroying disease-germs or the noxious properties of decaying organic matter.
- Diuretics.**—Medicines which increase the secretion of urine.
- Drastics.**—Purgatives which cause much irritation.
- Ecbolics.**—Medicines which produce abortion.
- Eccoprotics, or Ectoprotics.**—Laxatives.
- Emetics.**—Medicines which cause vomiting.
- Emmenagogues.**—Medicines which stimulate menstruation.
- Emollients.**—Substances used to mechanically soften and protect tissues.
- Epispastics.**—Blisters.
- Errhines.**—Medicines which increase the nasal secretions.
- Escharotics.**—Caustics.
- Evacuants.**—Medicines which evacuate : chiefly applied to purgatives.
- Excitants.**—Stimulants.
- Excito-Motors.**—Medicines which increase motor activity.
- Expectorants.**—Medicines which act upon the pulmonic mucous membrane and increase or alter its secretions.
- Febrifuges.**—Medicines which dissipate fever.
- Galactagogues.**—Medicines which increase the secretion of milk.
- Hæmostatics.**—Medicines which arrest hemorrhages.
- Hydragogues.**—Purgatives which cause large watery discharges.
- Hypnotics.**—Medicines which cause sleep.
- Laxatives.**—Mild purgatives.
- Local Anæsthetics.**—Medicines which when applied locally destroy sensation.
- Mydriatics.**—Medicines which cause *mydriasis*, or dilatation of the pupil.
- Myotics.**—Medicines which cause *myosis*, or contraction of the pupil.
- Narcotics.**—Powerful anodyne hypnotics.
- Neurotics.**—Medicines which act upon the nervous system.
- Nutriants.**—Medicines which modify the nutritive processes.
- Nutrients.**—Substances which nourish.
- Oxytocics.**—Medicines which stimulate uterine contractions.
- Peristaltics.**—Medicines which increase peristalsis.
- Prophylactics.**—Medicines which prevent the taking or development of disease.
- Protectives.**—Medicines which protect a part when applied to it.
- Ptyalagogues.**—Sialagogues.
- Purgatives.**—Medicines which produce copious discharges from the bowels.
- Refrigerants.**—Medicines which lessen the bodily temperature.
- Revulsants.**—Medicines which by causing irritation draw nervous force and blood from a distant diseased part.
- Rubefaciants.**—Medicines which cause irritation and redness, and are used as revulsants.
- Sedatives.**—Medicines which lower functional activity.
- Sialagogues.**—Medicines which excite the salivary glands to secretion.
- Somnifaciants.**—Soporifics.
- Soporifics.**—Medicines which cause sleep.
- Sorbefaciants.**—Medicines which cause absorption.
- Specifics.**—Medicines which have a direct curative influence on certain individual diseases.
- Stimulants.**—Medicines which increase functional activity.
- Stomachics.**—Stimulants to the stomach.
- Styptics.**—Hæmostatics.
- Sudorifics.**—Medicines which produce sweating.
- Tænicides.**—Medicines which kill the tapeworm.
- Tonics.**—Medicines which permanently increase the systemic tone by stimulating nutrition.
- Vermicides.**—Medicines which kill intestinal worms.
- Vermifuges.**—Medicines which cause the expulsion of intestinal worms.
- Vesicatories.**—Blisters.

INDEX OF DISEASES.

Abortion.

Black haw, 1334
Caulophyllum, 1438
Ergot, 452
European pennyroyal, 1563
Salipyrin, 1639

Abrasion.

Iodoform, 661
Magnesia, 755

Abscess.

Airol, 1373
Alumol, 1377
Borax, 1134
Chlorine water, 710
Echinacea, 1476
Germander, 1672
Glybolid, 1504
Iodine, 669
Iodine eigne, 1477
Iodoform, 662
Oleate of mercury, 823
Orthoform, 1597
Potassium permanganate, 1015

Acne.

Euresol, 1501
Fanghi di sclofani, 1487
Ichthyol, 1523
Lappa, 690
Lignol, 1549
Lysulfol, 1555
Mercuric nitrate, solution of, 723
Oil of cajuput, 838
Sulphurated lime, 271

Addison's Disease.

Suprarenal glands, 584

Adenitis.

See *Glands, Enlarged.*

Albuminuria.

Galic acid, 30
Koumys, 1542
Strontium lactate, 1662
Tannalbin, 1667
See also *Bright's Disease.*

Alcoholism.

Capsicum, 291
Gold and sodium chloride, 220

Alopecia.

Dupuytren's ointment, 1307
Oil of savin, 873

Amaurosis.

Euphorbium, 1485
Santonin, 1087

Amenorrhœa.

Achillea, 1368
Aloes, 116
Aloes and iron, pills of, 953
Aloes and myrrh, pills of, 954
Aloes and myrrh, tincture of, 1253
Aloes, compound decoction of, 422
Ammoniated iron, 1533
Ammonium chloraurate, 1506
Apiol, 1393
Bistort, 1417
Black hellebore, 1515
Blessed thistle, 1439
Calendula, 263
Cantharides, 287
Caper bush, 1430
Castor, 1435
Caulophyllum, 1438
Croton oil, 887
Ferric phosphate, 509
Ferrous iodide, 1490
Galbanum, 572
Gentian, 582
Germander, 1672
Ground pine, 1373
Guaiac, ammoniated tincture of, 1269
Guaiac, tincture of, 1269
Hedeoma, 610
Indigo, 1529
Inula, 1531
Leonurus cardiaca, 1548
Manganese dioxide, 761
Marrubium, 767
Mugwort, 1366
Myrrh, 801
Oil of amber, 1379
Oil of hedeoma, 849
Oil of savin, 873
Oil of turpentine, 880
Oxalic acid, 1600
Parsley, 1393
Potassium permanganate, 1015
Rubia, 1634
Ruta, 1636
Sagapenum, 1637
Santonin, 1087
Savin, 1070
Senecio, 1646
Shepherd's purse, 1430
Sumbul, 1210
Tang-kui, 1667
Tansy, 1667
Water-pepper, 1417

Anemia.

Arrhenal, 1651
Blaud's pills, 956
Cactus, 1424

Anemia.

Copper arsenite, 1459
Euquinine, 1486
Ferric albuminate, 1487
Ferric valerate, 1489
Ferripyrine, 1489
Ferro-manganic preparations, 1560
Ferrocol, 1489
Ferrous carbonate, 768
Fersan, 1492
Gold pentabromide, 1506
Iron, 516
Kefir, 1540
Manganese sulphate, 763
Manganous iodide, 1559
Myrrh, 801
Nickel carbonate, 1579
Nuclein, 1583
Sodium caseinate, 1651
Strychnine, 1194
Sumbul, 1210
Vanadic acid, 1690
Vanadium, 1690
See also *Chlorosis.*

Anæsthesia, Accidents of

Strychnine, 1195

Anchylostoma.

Thymol urethane, 1677

Aneurism.

Ferric chloride, 495
Ferric chloride, solution of, 715
Gelatin, 577
Lead acetate, 970
Nitrated alcohols, 1580
Potassium iodide, 1009

Angina.

See *Sore Throat.*

Angina Pectoris.

Amyl nitrite, 142
Erythrol tetranitrate, 1480
Nitrated alcohols, 1580
Nitroglycerin, 1177
Pellote, 1387
Salicylbromanilide, 1639

Anorexia.

Orexin tannate, 1596
Quassia, 1033

Anthrax.

Blepharis, 1418
Silver fluoride, 1494

Antimony Poisoning.

Treatment of, 150

Anus, Fissure of.See *Fissure*.**Anus, Prolapsed.**

Balsam-apple, 1571
 Krameria, 686
 Nutgall ointment, 1309
 Oak bark, 1035
 Rye, 1636
 Tannic acid, ointment of, 1305

Aphthæ.

Borax honey, 774
 Boric acid, 24
 Geranium, 583
 Goldthread, 1459
 Myrrh, 802
 Myrrh, tincture of, 1278
 Sodium borate, 1135
 Sodium sulphite, 1158
 Tannic acid, 82
 See also *Stomatitis*.

Apoplexy.

Ergot, 452

Arsenical Poisoning.

Ferric hydroxide, 506
 Ferric hydroxide with magnesium oxide, 507

Arterial Sclerosis.

Potassium nitrate, 1013

Arthritis.

Cantharides, 288
 Cod liver oil, 860
 Lead tannate, 1547
 Mercury, oleate of, 823
 Pyrosal, 1625
 Veratrine, 1330

Ascaris Lumbricoides.

Aloes, 116
 Azedarach, 1404
 Cabbage-tree bark, 1423
 Chenopodium, 1442
 Cod liver oil, 860
 Cowhage, 1573
 Oil of turpentine, 880
 Santonin, 1087
 See also *Worms*.

Ascaris Vermicularis.

Aloes, 116
 Cod liver oil, 860
 Naphthalene, 802
 Oil of turpentine, 880
 Vinegar, 1693

Ascites.

Iodine, 667, 669
 Iodine, tincture of, 1272
 Mercury, 636
 Orthosiphon, 1598

Asphyxia.

Acetic acid, 19

Asthma.

Allyl bromide (note), 877
 Allyl tribromide, 1376
 Ammoniac, 127

Asthma.

Amyl nitrite, 142
 Arum, 1399
 Asafetida, 209
 Asclepias syriaca, 1401
 Aspidosperma, 1403
 Atropine, 215
 Balsam of Peru, 223
 Belladonna, 229
 Bitter candytuft, 1521
 Caruba di guiden, 1432
 Catalpa, 1435
 Chloral hydrate, 326
 Chloroform, 332
 Cobweb, 1451
 Colchicum, 383
 Creosote iodide, 1465
 Cuckoo flower, 1431
 Delphinium, 1472
 Dionine, 1473
 Dracontium, 1475
 Eriodictyon, 453
 Eucalyptus, 456
 Euphorbia pilulifera, 1484
 Evening primrose, 1584
 Grindelia, 601
 Honeysuckle, 1554
 Iodine eigone, 1477
 Iodopyrine, 1532
 Ipecac, 675
 Laburnum, 1471
 Lobelia, 748
 Lobelia, tincture of, 1276
 Lobelia, vinegar of (note), 749
 Nitrated alcohols, 1580
 Nitroglycerin, 1177
 Opopanax, 1595
 Oxymel of squill, 911
 Paraldehyde, 915
 Pellote, 1387
 Petroleum, 1610
 Polypodium, 1617
 Potassium cobalt-nitrite, 1619
 Potassium nitrate, 1013
 Potassium nitrate paper, 319
 Pyramidon, 1624
 Pyridine, 1625

 Osgall, 491
 Pareira brava, 917
 Potassium permanganate, 1015
 Rattlesnake root, 1576
 Simaruba, 1649
 Treatment of (note), 1015

Bladder, Catarrh of.See *Cystitis*.**Bladder, Irritable.**

Belladonna leaves, extract of, 471
 Peach leaves, 1605
 Triticum, 1296

Bladder, Ulcer of.

Pareira brava, 917
 Uva ursi, 1321

Blisters.

Lead carbonate ointment, 1317
 Lead subacetate, solution of, 730
 Rosin cerate, 315
 Spermaceti ointment, 1308

Boils.

Echinacea, 1476
 Elm, mucilage of, 797
 Iodine, colorless tincture of (note), 1272
 Menthol, 778
 Mercuric nitrate, solution of, 723
 Phenol, 930
 Sulphurated lime, 271
 Yeast, 1701

Bones, Delayed Union of.

Calcium phosphate, 262

Bones, Diseases of.

Balsam of Peru, 223
 Calcium phosphate, 262
 Red mercuric iodide, 630
 Sodium hypophosphite, 1147

Brain, Congestion of.

Chloral hydrate, 326
 Ergot, 452

Brain, Inflammation of.

Chloral hydrate, 326

Brain, Softening of.

Phosphorus, 935

Breasts, Inflammation of.See *Mastitis*.**Bright's Disease.**

Ammonium benzoate, 128

Bright's Disease.

Apocynum, 159
 Basham's mixture, 716
 Caffeine, 254
 Carrot seeds, 1432
 Chondrus, 334
 Ferrie chloride, tincture of, 1267
 Fuch sine, 1498
 Gallic acid, 30
 Herb Robert, 1502
 Horsetail, 1479
 Linseed meal, 701
 Lycopodium, 750
 Mallow, 1558
 Mucilage of elm, 797
 Oil of turpentine, 880
 Opium, 909
 Pareira brava, 917
 Parsley, 1393
 Pilocarpus, 949
 Sassafras pith, 1098
 Speedwell, 1691
 Strontium lactate, 1662
 Symphoricarpos, 1665
 Theobromine, 883
 Theocine, 1699
 Uva ursi, 1321
 Viola, 1694

Bronchitis.

Acetopyrine, 1367
 Ammonium carbonate, 131
 Ammonium chloride, 133
 Antimony and potassium nitrate, 150
 Aspidosperma, 1403
 Atherosperma, 1404
 Bitter candytuft, 1521
 Camphoric acid, 25
 Chlorsalol, 1448
 Cocaine, 373
 Cocillana bark, 1452
 Coltsfoot, 1685
 Creosote, 404
 Eucalyptol, 454
 Eucalyptus, 456
 Euphorbia pilulifera, 1484
 Garlic, 1375
 Grindelia, 601
 Guaiacal, 603
 Heroine hydrochloride, 1516
 Hound's tongue, 1471
 Hydrogen sulphide, 1520
 Iodine, 669
 Ipecac, 675
 Laburnum, 1471
 Larch bark, 1545
 Mercury, 636
 Naregamia, 1577
 Oil of cajuput, 838
 Oil of santal, 875
 Oil of satin wood, 1537
 Olibanum, 1594
 Onion, 1595
 Peronine, 1607
 Potassium citrate, 995
 Senega, 1109
 Solanine, 1655
 Spanish needles, 1414
 Squill, syrup of, 1234
 Strychnine, 1195
 Sugar, 1076
 Terebene, 1242
 Terpin hydrate, 1249

Bronchitis.

Thiocol, 1675
 Tylophora, 1686
 Water hemlock, 1584

Bronchitis, Chronic.

Ammonium chloride, 133
 Benzoic acid, 22
 Caruba di guiden, 1432
 Cheken, 1483
 Chlorine, 710
 Copaiba, 401
 Creosote carbonate, 1465
 Cubeb, 412
 Eriodictyon, 453
 Ethyl iodide, 1482
 Eucalyptol, 454
 Euphorbia, 1484
 Garlic, 1375
 Myrtle, 1576
 Naphthalene, 802
 Onion, 1595
 Petrolatum, 924
 Physostigma, 939
 Pill of ipecac and squill, 958
 Sabal, 1069
 Sanguinaria, 1083
 Senega, 1109
 Squill, compound pill of, 961
 Strychnine, 1195
 Sumbul, 1210
 Tar, 968
 Terebene, 1242
 Terpin hydrate, 1249
 Terpinol, 1672
 Thiocol, 1675
 Tolu, tincture of, 1289

Bronchocele.

Bromine, 249
 Iodine, 669
 Potassium bromide, 989

Bronchorrhœa.

Eucalyptol, 454

Bruises.

Ammonium chloride, 133
 Arnica root, 196
 Arnica, tincture of, 1254
 Calendula, tincture of, 263
 Camphor, 278
 Camphor liniment, 696

THE FOOD AND DRUGS ACT.

In force and effect from and after January 1, 1907.

THE Food and Drugs Act, passed by the Congress of the United States, June 30th, 1906, is of such vital importance to the readers of the United States Dispensatory that it is reproduced here, in order that every manufacturer, wholesale, jobbing, or retail druggist, dealer, or other interested party, may have in permanent form a copy of the Act, together with the official regulations for the enforcement of the same, as published by the United States Department of Agriculture in their official circular. It is as follows :

AN ACT For preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be unlawful for any person to manufacture within any Territory or the District of Columbia any article of food or drug which is adulterated or misbranded, within the meaning of this Act ; and any person who shall violate any of the provisions of this section shall be guilty of a misdemeanor, and for each offense shall, upon conviction thereof, be fined not to exceed five hundred dollars or shall be sentenced to one year's imprisonment, or both such fine and imprisonment, in the discretion of the court, and for each subsequent offense and conviction thereof shall be fined not less than one thousand dollars or sentenced to one year's imprisonment, or both such fine and imprisonment in the discretion of the court.

SEC. 2. That the introduction into any State or Territory or the District of Columbia from any other State or Territory or the District of Columbia, or from any foreign country, or shipment to any foreign country of any article of food or drugs which is adulterated or misbranded, within the meaning of this Act, is hereby prohibited ; and any person who shall ship or deliver for shipment from any State or Territory or the District of Columbia to any other State or Territory or the District of Columbia, or to a foreign country, or who shall receive in any State or Territory or the District of Columbia from any other State or Territory or the District of Columbia, or foreign country, and having so received, shall deliver, in original unbroken packages, for pay or otherwise, or offer to deliver to any other person, any such article so adulterated or misbranded within the meaning of this Act, or any person who shall sell or offer for sale in the District of Columbia or the Territories of the United States any such adulterated or misbranded foods or drugs, or export or offer to export the same to any foreign country, shall be guilty of a misdemeanor, and for such offense be fined not exceeding two hundred dollars for the first offense, and upon conviction for each subsequent offense not exceeding three hundred dollars or be imprisoned not exceeding one year, or both, in the discretion of the court : *Provided*, That no article shall be deemed misbranded or adulterated within the provisions of this Act when intended for export to any foreign country and prepared or packed according to the specifications or directions of the foreign purchaser when no substance is used in the preparation or packing thereof in conflict with the laws of the foreign country to which said article is intended to be shipped ; but if said article shall be in fact sold or offered for sale for domestic use or consumption, then this proviso shall not exempt said article from the operation of any of the other provisions of this Act.

SEC. 3. That the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor shall make uniform rules and regulations for carrying out the provisions of this Act, including the collection and examination of specimens of foods and drugs manufactured or offered for sale in the District of Columbia, or in any Territory of the United States, or which shall be offered for sale in unbroken packages in any State other than that in which they shall have been respectively manufactured or produced, or which shall be received from any foreign country, or intended for shipment to any foreign country, or which may be submitted for examination by the chief health, food, or drug officer of any State, Territory, or the District of Columbia, or at any domestic or foreign port through which such product is offered for interstate commerce, or for export or import between the United States and any foreign port or country.

SEC. 4. That the examinations of specimens of foods and drugs shall be made in the Bureau of Chemistry of the Department of Agriculture, or under the direction and supervision of such Bureau, for the purpose of determining from such examinations whether such articles are adulterated or misbranded within the meaning of this Act; and if it shall appear from any such examination that any of such specimens is adulterated or misbranded within the meaning of this Act, the Secretary of Agriculture shall cause notice thereof to be given to the party from whom such sample was obtained. Any party so notified shall be given an opportunity to be heard, under such rules and regulations as may be prescribed as aforesaid, and if it appears that any of the provisions of this Act have been violated by such party, then the Secretary of Agriculture shall at once certify the facts to the proper United States district attorney, with a copy of the results of the analysis or the examination of such article duly authenticated by the analyst or officer making such examination, under the oath of such officer. After judgment of the court, notice shall be given by publication in such manner as may be prescribed by the rules and regulations aforesaid.

SEC. 5. That it shall be the duty of each district attorney to whom the Secretary of Agriculture shall report any violation of this Act, or to whom any health or food or drug officer or agent of any State, Territory, or the District of Columbia shall present satisfactory evidence of any such violation, to cause appropriate proceedings to be commenced and prosecuted in the proper courts of the United States, without delay, for the enforcement of the penalties as in such case herein provided.

SEC. 6. That the term "drug," as used in this Act, shall include all medicines and preparations recognized in the United States Pharmacopœia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation, or prevention of disease of either man or other animals. The term "food," as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or other animals, whether simple, mixed, or compound.

SEC. 7. That for the purposes of this Act an article shall be deemed to be adulterated:

In case of drugs:

First. If, when a drug is sold under or by a name recognized in the United States Pharmacopœia or National Formulary, it differs from the standard of strength, quality, or purity, as determined by the test laid down in the United States Pharmacopœia or National Formulary official at the time of investigation: *Provided*, That no drug defined in the United States Pharmacopœia or National Formulary shall be deemed to be adulterated under this provision if the standard of strength, quality, or purity be plainly stated upon the bottle, box, or other container thereof although the standard may differ from that determined by the test laid down in the United States Pharmacopœia or National Formulary.

Second. If its strength or purity fall below the professed standard or quality under which it is sold.

In the case of confectionery :

If it contain terra alba, barytes, tale, chrome yellow, or other mineral substance or poisonous color or flavor, or other ingredient deleterious or detrimental to health, or any vinous, malt, or spirituous liquor or compound or narcotic drug.

In the case of food :

First. If any substance has been mixed and packed with it so as to reduce or lower or injuriously affect its quality or strength.

Second. If any substance has been substituted wholly or in part for the article.

Third. If any valuable constituent of the article has been wholly or in part abstracted.

Fourth. If it be mixed, colored, powdered, coated, or stained in a manner whereby damage or inferiority is concealed.

Fifth. If it contain any added poisonous or other added deleterious ingredient which may render such article injurious to health : *Provided*, That when in the preparation of food products for shipment they are preserved by any external application applied in such manner that the preservative is necessarily removed mechanically, or by maceration in water, or otherwise, and directions for the removal of said preservative shall be printed on the covering or the package, the provisions of this Act shall be construed as applying only when said products are ready for consumption.

Sixth. If it consists in whole or in part of a filthy, decomposed, or putrid animal or vegetable substance, or any portion of an animal unfit for food, whether manufactured or not, or if it is the product of a diseased animal, or one that has died otherwise than by slaughter.

SEC. 8. That the term "misbranded," as used herein, shall apply to all drugs, or articles of food, or articles which enter into the composition of food, the package or label of which shall bear any statement, design, or device regarding such article, or the ingredients or substances contained therein which shall be false or misleading in any particular, and to any food or drug product which is falsely branded as to the State, Territory, or country in which it is manufactured or produced.

That for the purposes of this Act an article shall also be deemed to be misbranded:

In case of drugs :

First. If it be an imitation of or offered for sale under the name of another article.

Second. If the contents of the package as originally put up shall have been removed, in whole or in part, and other contents shall have been placed in such package, or if the package fail to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, cocaine, heroin, alpha or beta eucaïne, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any of such substances contained therein.

In the case of food :

First. If it be an imitation of or offered for sale under the distinctive name of another article.

Second. If it be labeled or branded so as to deceive or mislead the purchaser, or purport to be a foreign product when not so, or if the contents of the package as originally put up shall have been removed in whole or in part and other contents shall have been placed in such package, or if it fail to bear a statement on the label of the quantity or proportion of any morphine, opium, cocaine, heroin, alpha or beta eucaïne, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any such substances contained therein.

Third. If in package form, and the contents are stated in terms of weight or measure, they are not plainly and correctly stated on the outside of the package.

Fourth. If the package containing it or its label shall bear any statement, design, or device regarding the ingredients or the substances contained therein, which statement,

design, or device shall be false or misleading in any particular: *Provided*, That an article of food which does not contain any added poisonous or deleterious ingredients shall not be deemed to be adulterated or misbranded in the following cases:

First. In the case of mixtures or compounds which may be now or from time to time hereafter known as articles of food, under their own distinctive names, and not an imitation of or offered for sale under the distinctive name of another article, if the name be accompanied on the same label or brand with a statement of the place where said article has been manufactured or produced.

Second. In the case of articles labeled, branded, or tagged so as to plainly indicate that they are compounds, imitations, or blends, and the word "compound," "imitation," or "blend," as the case may be, is plainly stated on the package in which it is offered for sale: *Provided*, That the term blend as used herein shall be construed to mean a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only: *And provided further*, That nothing in this Act shall be construed as requiring or compelling proprietors or manufacturers of proprietary foods which contain no unwholesome added ingredient to disclose their trade formulas, except in so far as the provisions of this Act may require to secure freedom from adulteration or misbranding.

SEC. 9. That no dealer shall be prosecuted under the provisions of this Act when he can establish a guaranty signed by the wholesaler, jobber, manufacturer, or other party residing in the United States, from whom he purchases such articles, to the effect that the same is not adulterated or misbranded within the meaning of this Act, designating it. Said guaranty, to afford protection, shall contain the name and address of the party or parties making the sale of such articles to such dealer, and in such case said party or parties shall be amenable to the prosecutions, fines, and other penalties which would attach, in due course, to the dealer under the provisions of this Act.

SEC. 10. That any article of food, drug, or liquor that is adulterated or misbranded within the meaning of this Act, and is being transported from one State, Territory, District, or insular possession to another for sale, or, having been transported, remains unloaded, unsold, or in original unbroken packages, or if it be sold or offered for sale in the District of Columbia or the Territories, or insular possessions of the United States, or if it be imported from a foreign country for sale, or if it is intended for export to a foreign country, shall be liable to be proceeded against in any district court of the United States within the district where the same is found, and seized for confiscation by a process of libel for condemnation. And if such article is condemned as being adulterated or misbranded, or of a poisonous or deleterious character, within the meaning of this Act, the same shall be disposed of by destruction or sale, as the said court may direct, and the proceeds thereof, if sold, less the legal costs and charges, shall be paid into the Treasury of the United States, but such goods shall not be sold in any jurisdiction contrary to the provisions of this Act or the laws of that jurisdiction: *Provided, however*, That upon the payment of the costs of such libel proceedings and the execution and delivery of a good and sufficient bond to the effect that such articles shall not be sold or otherwise disposed of contrary to the provisions of this Act, or the laws of any State, Territory, District, or insular possession, the court may by order direct that such articles be delivered to the owner thereof. The proceedings of such libel cases shall conform, as near as may be, to the proceedings in admiralty, except that either party may demand trial by jury of any issue of fact joined in any such case, and all such proceedings shall be at the suit of and in the name of the United States.

SEC. 11. The Secretary of the Treasury shall deliver to the Secretary of Agriculture, upon his request from time to time, samples of foods and drugs which are being imported into the United States or offered for import, giving notice thereof to the owner or consignee, who may appear before the Secretary of Agriculture, and have the right to intro-

duce testimony, and if it appear from the examination of such samples that any article of food or drug offered to be imported into the United States is adulterated or misbranded within the meaning of this Act, or is otherwise dangerous to the health of the people of the United States, or is of a kind forbidden entry into, or forbidden to be sold or restricted in sale in the country in which it is made or from which it is exported, or is otherwise falsely labeled in any respect, the said article shall be refused admission, and the Secretary of the Treasury shall refuse delivery to the consignee and shall cause the destruction of any goods refused delivery which shall not be exported by the consignee within three months from the date of notice of such refusal under such regulations as the Secretary of the Treasury may prescribe: *Provided*, That the Secretary of the Treasury may deliver to the consignee such goods pending examination and decision in the matter on execution of a penal bond for the amount of the full invoice value of such goods, together with the duty thereon, and on refusal to return such goods for any cause to the custody of the Secretary of the Treasury, when demanded, for the purpose of excluding them from the country, or for any other purpose, said consignee shall forfeit the full amount of the bond: *And provided further*, That all charges for storage, cartage, and labor on goods which are refused admission or delivery shall be paid by the owner or consignee, and in default of such payment shall constitute a lien against any future importation made by such owner or consignee.

SEC. 12. That the term "Territory" as used in this Act shall include the insular possessions of the United States. The word "person" as used in this Act shall be construed to import both the plural and the singular, as the case demands, and shall include corporations, companies, societies and associations. When construing and enforcing the provisions of this Act, the act, omission, or failure of any officer, agent, or other person acting for or employed by any corporation, company, society, or association, within the scope of his employment or office, shall in every case be also deemed to be the act, omission, or failure of such corporation, company, society, or association as well as that of the person.

SEC. 13. That this Act shall be in force and effect from and after the first day of January, nineteen hundred and seven.

Approved, June 30, 1906.

RULES AND REGULATIONS FOR THE ENFORCEMENT OF THE FOOD AND DRUGS ACT.

GENERAL.

Regulation 1. Short Title of the Act.

The act, "For preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, and liquors, and for regulating traffic therein, and for other purposes," approved June 30, 1906, shall be known and referred to as "The Food and Drugs Act, June 30, 1906."

Regulation 2. Original Unbroken Package.

(Section 2.)

The term "original unbroken package" as used in this act is the original package, carton, case, can, box, barrel, bottle, phial, or other receptacle put up by the manufacturer, to which the label is attached, or which may be suitable for the attachment of a label, making one complete package of the food or drug article. The original package contemplated includes both the wholesale and the retail package.

Regulation 3. Collection of Samples.

(Section 4.)

Samples of unbroken packages shall be collected only by authorized agents of the Department of Agriculture; or by the health, food, or drug officer of any State, Territory, or the District of Columbia, when commissioned by the Secretary of Agriculture for this purpose.

Samples may be purchased in the open market, and if in bulk the marks, brands, or tags upon the package, carton, container, wrapper, or accompanying printed or written matter shall be noted. The collector shall also note the names of the vendor and agent thru whom the sale was actually made, together with the date of purchase. The collector shall purchase representative samples.

A sample shall be divided into three parts, and each part shall be labeled with the identifying marks. All samples shall be sealed by the collector with a seal provided for the purpose. If the package be less than four pounds, or in volume less than two quarts, three packages of approximately the same size shall be purchased and the marks and tags upon each noted as above. One sample shall be delivered to the party from whom purchased or to the party guaranteeing such merchandise. One sample shall be sent to the Bureau of Chemistry, or to such chemist or examiner as may be designated by the Secretary of Agriculture, and the third sample shall be held under seal by the Secretary of Agriculture.

Regulation 4. Methods of Analysis.

(Section 4.)

Unless otherwise directed by the Secretary of Agriculture, the methods of analysis employed shall be those prescribed by the Association of Official Agricultural Chemists and the United States Pharmacopœia.

Regulation 5. Hearings.

(Section 4.)

(a) When the examination or analysis shows that the provisions of the food and drugs act, June 30, 1906, have been violated, notice of that fact, together with a copy of the findings, shall be furnished to the party or parties from whom the sample was obtained or who executed the guaranty as provided in the food and drugs act, June 30, 1906, and a date shall be fixt at which such party or parties may be heard before the Secretary of Agriculture, or such other official connected with the food and drug inspection service as may be commissioned by him for that purpose. The hearings shall be had at a place, to be designated by the Secretary of Agriculture, most convenient for all parties concerned. These hearings shall be private and confined to questions of fact. The parties interested therein may appear in person or by attorney and may propound proper interrogatories and submit oral or written evidence to show any fault or error in the findings of the analyst or examiner. The Secretary of Agriculture may order a re-examination of the sample or have new samples drawn for further examination.

(b) If the examination or analysis be found correct the Secretary of Agriculture shall give notice to the United States district attorney as prescribed.

(c) Any health, food, or drug officer or agent of any State, Territory, or the District of Columbia who shall obtain satisfactory evidence of any violation of the food and drugs act, June 30, 1906, as provided in section 5 thereof, shall first submit the same to the Secretary of Agriculture, in order that the latter may cause notice to be given to the guarantor or to the party from whom the sample was obtained.

Regulation 6. Publication.

(Section 4.)

(a) When a judgment of the court shall have been rendered there may be a publication of the findings of the examiner or analyst, together with the findings of the court.

(b) This publication may be made in the form of circulars, notices, or bulletins, as the Secretary of Agriculture may direct, not less than thirty days after judgment.

(c) If an appeal be taken from the judgment of the court before such publication, notice of the appeal shall accompany the publication.

Regulation 7. Standards for Drugs.

(Section 7.)

(a) A drug bearing a name recognized in the United States Pharmacopœia or National Formulary, without any further statement respecting its character, shall be required to conform in strength, quality, and purity to the standards prescribed or indicated for a drug of the same name recognized in the United States Pharmacopœia or National Formulary, official at the time.

(b) A drug bearing a name recognized in the United States Pharmacopœia or National Formulary, and branded to show a different standard of strength, quality, or purity, shall not be regarded as adulterated if it conforms to its declared standard.

Regulation 8. Formulas—Proprietary Foods.

(Section 8, last paragraph.)

(a) Manufacturers of proprietary foods are only required to state upon the label the names and percentages of the materials used, in so far as the Secretary of Agriculture may find this to be necessary to secure freedom from adulteration and misbranding.

(b) The factories in which proprietary foods are made shall be open at all reasonable times to the inspection provided for in Regulation 16.

Regulation 9. Form of Guaranty.

(Section 9.)

(a) No dealer in food or drug products will be liable to prosecution if he can establish that the goods were sold under a guaranty by the wholesaler, manufacturer, jobber, dealer, or other party residing in the United States from whom purchased.

(b) A general guaranty may be filed with the Secretary of Agriculture by the manufacturer or dealer and be given a serial number, which number shall appear on each and every package of goods sold under such guaranty with the words, "Guaranteed under the food and drugs act, June 30, 1906."

(c) The following form of guaranty is suggested :

I (we) the undersigned do hereby guarantee that the articles of foods or drugs manufactured, packed, distributed, or sold by me (us) [specifying the same as fully as possible] are not adulterated or misbranded within the meaning of the food and drugs act, June 30, 1906.

(Signed in ink.)

[Name and place of business of wholesaler, dealer, manufacturer, jobber, or other party.]

(d) If the guaranty be not filed with the Secretary of Agriculture as above, it should identify and be attached to the bill of sale, invoice, bill of lading, or other schedule giving the names and quantities of the articles sold.

ADULTERATION.

Regulation 10. Confectionery.

(Section 7.)

(a) Mineral substances of all kinds (except as provided in Regulation 15) are specifically forbidden in confectionery whether they be poisonous or not.

(b) Only harmless colors or flavors shall be added to confectionery.

(c) The term "narcotic drugs" includes all the drugs mentioned in section 8, food and drugs act, June 30, 1906, relating to foods, their derivatives and preparations, and all other drugs of a narcotic nature.

Regulation 11. Substances Mixt and Packed with Foods.

(Section 7, under "Foods.")

No substance may be mixt or packed with a food product which will reduce or lower its quality or strength. Not excluded under this provision are substances properly used in the preparation of food products for clarification or refining, and eliminated in the further process of manufacture.

Regulation 12. Coloring, Powdering, Coating, and Staining.

(Section 7, under "Foods.")

(a) Only harmless colors may be used in food products.

(b) The reduction of a substance to a powder to conceal inferiority in character is prohibited.

(c) The term "powdered" means the application of any powdered substance to the exterior portion of articles of food, or the reduction of a substance to a powder.

(d) The term "coated" means the application of any substance to the exterior portion of a food product.

(e) The term "stain" includes any change produced by the addition of any substance to the exterior portion of foods which in any way alters their natural tint.

Regulation 13. Natural Poisonous or Deleterious Ingredients.

(Section 7, paragraph 5, under "Foods.")

Any food product which contains naturally a poisonous or deleterious ingredient does not come within the provisions of the food and drugs act, June 30, 1906, except when the presence of such ingredient is due to filth, putrescence, or decomposition.

Regulation 14. External Application of Preservatives.

(Section 7, paragraph 5, under "Foods," proviso.)

(a) Poisonous or deleterious preservatives shall only be applied externally, and they and the food products shall be of a character which shall not permit the permeation of any of the preservative to the interior, or any portion of the interior, of the product.

(b) When these products are ready for consumption, if any portion of the added preservative shall have penetrated the food product, then the proviso of section 7, paragraph 5, under "Foods," shall not obtain, and such food products shall then be subject to the regulations for food products in general.

(c) The preservative applied must be of such a character that, until removed, the food products are inedible.

Regulation 15. Wholesomeness of Colors and Preservatives.

(Section 7, paragraph 5, under "Foods.")

(a) Respecting the wholesomeness of colors, preservatives, and other substances which are added to foods, the Secretary of Agriculture shall determine from chemical or other examination, under the authority of the agricultural appropriation act, Public 382, approved June 30, 1906, the names of those substances which are permitted or inhibited in food products; and such findings, when approved by the Secretary of the Treasury and the Secretary of Commerce and Labor, shall become a part of these regulations.

(b) The Secretary of Agriculture shall determine from time to time, in accordance with the authority conferred by the agricultural appropriation act, Public 382, approved June 30, 1906, the principles which shall guide the use of colors, preservatives, and other substances added to foods; and when concurred in by the Secretary of the Treasury and the Secretary of Commerce and Labor, the principles so established shall become a part of these regulations.

Regulation 16. Character of the Raw Materials.

(Section 7, paragraph 1, under "Drugs;" paragraph 6, under "Foods.")

(a) The Secretary of Agriculture, when he deems it necessary, shall examine the raw materials used in the manufacture of food and drug products, and determine whether any filthy, decomposed, or putrid substance is used in their preparation.

(b) The Secretary of Agriculture shall make such inspections as often as he may deem necessary.

MISBRANDING.

Regulation 17. Label.

(Section 8.)

(a) The term "label" applies to any printed, pictorial, or other matter upon or attached to any package of a food or drug product, or any container thereof.

(b) The principal label shall consist, first, of all words which the food and drugs act, June 30, 1906, specifically requires, to wit, the name of the substance or product; the name of place of manufacture in the case of food compounds or mixtures; words which show that the articles are compounds, mixtures, or blends; the words "compound," "mixture," or "blend;" or words designating the substances or their derivatives and proportions required to be named in the case of drugs and foods. All these required words shall appear upon the principal label with no intervening descriptive or explanatory reading matter. Second, if the name of the manufacturer and place of manufacture are given, they shall also appear upon the principal label. Third, elsewhere upon the principal label other matter may appear in the discretion of the manufacturer.

(c) The principal label on foods or drugs for domestic commerce shall be printed in English (except as provided in Regulation 19), with or without the foreign label in the language of the country where the food or drug product is produced or manufactured. The size of type shall not be smaller than 8-point (brevier) caps: *Provided*, That in case the size of the package will not permit the use of 8-point cap type the size of the type may be reduced proportionately.

(d) The form, character, and appearance of the labels, except as provided above, are left to the judgment of the manufacturer.

(e) Descriptive matter upon the label shall be free from any statement, design, or device regarding the article or the ingredients or substances contained therein, or quality thereof, or place of origin, which is false or misleading in any particular.

(f) An article containing more than one food product or active medicinal agent is misbranded if named after a single constituent.

In the case of drugs the nomenclature employed by the United States Pharmacopœia and the National Formulary shall obtain.

(g) The term "design" or "device" applies to pictorial matter of every description, and to abbreviations, characters, or signs for weights, measures, or names of substances.

(h) The use of any false or misleading statement, design, or device shall not be justified by any statement given as the opinion of an expert or other person, appearing on any part of the label, nor by any descriptive matter explaining the use of the false or misleading statement, design, or device.

(i) The regulation regarding the principal label will not be enforced until October 1, 1907, in the case of labels printed and now on hand, whenever any statement therein contained which is contrary to the food and drugs act, June 30, 1906, as to character of contents, shall be corrected by a supplemental label, stamp, or pastar. All other labels now printed and on hand may be used without change until October 1, 1907.

Regulation 18. Name and Address of Manufacturer.

(Section 8.)

(a) The name of the manufacturer or producer, or the place where manufactured, except in case of mixtures and compounds having a distinctive name, need not be given upon the label, but if given, must be the true name and the true place. The words "packed for ———," "distributed by ———," or some equivalent phrase, shall be added to the label in case the name which appears upon the label is not that of the actual manufacturer or producer, or the name of the place not the actual place of manufacture or production.

(b) When a person, firm, or corporation actually manufactures or produces an article of food or drug in two or more places, the actual place of manufacture or production of each particular package need not be stated on the label except when in the opinion of the Secretary of Agriculture the mention of any such place, to the exclusion of the others, misleads the public.

Regulation 19. Character of Name.

(Section 8.)

(a) A simple or unmixt food or drug product not bearing a distinctive name shall be designated by its common name in the English language, or, if a drug, by any name recognized in the United States Pharmacopœia or National Formulary. No further description of its components or qualities is required, except as to content of alcohol, morphine, etc.

(b) The use of a geographical name shall not be permitted in connection with a food or drug product not manufactured or produced in that place, when such name indicates that the article was manufactured or produced in that place.

(c) The use of a geographical name in connection with a food or drug product will not be deemed a misbranding when by reason of long usage it has come to represent a generic term and is used to indicate a style, type, or brand; but in all such cases the State or Territory where any such article is manufactured or produced shall be stated upon the principal label.

(d) A foreign name which is recognized as distinctive of a product of a foreign country shall not be used upon an article of domestic origin except as an indication of the type or style of quality or manufacture, and then only when so qualified that it can not be offered for sale under the name of a foreign article.

Regulation 20. Distinctive Name.

(Section 8.)

(a) A "distinctive name" is a trade, arbitrary, or fancy name which clearly distinguishes a food product, mixture, or compound from any other food product, mixture, or compound.

(b) A distinctive name shall not be one representing any single constituent of a mixture or compound.

(c) A distinctive name shall not misrepresent any property or quality of a mixture or compound.

(d) A distinctive name shall give no false indication of origin, character, or place of manufacture, nor lead the purchaser to suppose that it is any other food or drug product.

Regulation 21. Compounds, Imitations, or Blends Without Distinctive Name.

(Section 8.)

(a) The term "blend" applies to a mixture of like substances, not excluding harmless coloring or flavoring ingredients used for the purpose of coloring and flavoring only.

(b) If any age is stated, it shall not be that of a single one of its constituents, but shall be the average of all constituents in their respective proportions.

(c) Coloring and flavoring can not be used for increasing the weight or bulk of a blend.

(d) In order that colors or flavors may not increase the volume or weight of a blend, they are not to be used in quantities exceeding 1 pound to 800 pounds of the blend.

(e) A color or flavor can not be employed to imitate any natural product or any other product of recognized name and quality.

(f) The term "imitation" applies to any mixture or compound which is a counterfeit or fraudulent simulation of any article of food or drug.

Regulation 22. Articles without a Label.

(Section 8, paragraph 1, under "Drugs," paragraph 1, under "Foods.")

It is prohibited to sell or offer for sale a food or drug product bearing no label upon the package or no descriptive matter whatever connected with it, either by design, device, or otherwise, if said product be an imitation of or offered for sale under the name of another article.

Regulation 23. Proper Branding not a Complete Guaranty.

Packages which are correctly branded as to character of contents, place of manufacture, name of manufacturer, or otherwise, may be adulterated and hence not entitled to enter into interstate commerce.

Regulation 24. Incompleteness of Branding.

A compound shall be deemed misbranded if the label be incomplete as to the names of the required ingredients. A simple product does not require any further statement than the name or distinctive name thereof, except as provided in Regulations 19 (a) and 28.

Regulation 25. Substitution.

(Sections 7 and 8.)

(a) When a substance of a recognized quality commonly used in the preparation of a food or drug product is replaced by another substance not injurious or deleterious to health, the name of the substituted substance shall appear upon the label.

(b) When any substance which does not reduce, lower, or injuriously affect its quality or strength, is added to a food or drug product, other than that necessary to its manufacture or refining, the label shall bear a statement to that effect.

Regulation 26. Waste Materials.

(Section 8.)

When an article is made up of refuse materials, fragments, or trimmings, the use of the name of the substance from which they are derived, unless accompanied by a statement to that effect, shall be deemed a misbranding. Packages of such materials may be labeled "pieces," "stems," "trimmings," or with some similar appellation.

Regulation 27. Mixtures or Compounds with Distinctive Names.

(Section 8. First proviso under "Foods," paragraph 1.)

(a) The terms "mixtures" and "compounds" are interchangeable and indicate the results of putting together two or more food products.

(b) These mixtures or compounds shall not be imitations of other articles, whether simple, mixt, or compound, or offered for sale under the name of other articles. They shall bear a distinctive name and the name of the place where the mixture or compound has been manufactured or produced.

(c) If the name of the place be one which is found in different States, Territories, or countries, the name of the State, Territory, or country, as well as the name of the place, must be stated.

Regulation 28. Substances named in Drugs or Foods.

(Section 8. Second under "Drugs;" second under "Foods.")

(a) The term "alcohol" is defined to mean common or ethyl alcohol. No other kind of alcohol is permissible in the manufacture of drugs except as specified in the United States Pharmacopoeia or National Formulary.

(b) The words alcohol, morphine, opium, etc., and the quantities and proportions thereof, shall be printed in letters corresponding in size with those prescribed in Regulation 17, paragraph (c).

(c) A drug, or food product except in respect of alcohol, is misbranded in case it fails to bear a statement on the label of the quantity or proportion of any alcohol, morphine, opium, heroin, cocaine, alpha or beta eucaine, chloroform, cannabis indica, chloral hydrate, or acetanilide, or any derivative or preparation of any such substances contained therein.

(d) A statement of the maximum quantity or proportion of any such substances present will meet the requirements, provided the maximum stated does not vary materially from the average quantity or proportion.

(e) In case the actual quantity or proportion is stated it shall be the average quantity or proportion with the variations noted in Regulation 29.

(f) The following are the principal derivatives and preparations made from the articles which are required to be named upon the label:

ALCOHOL, ETHYL: (*Cologne spirits, Grain alcohol, Rectified spirits, Spirits, and Spirits of wine.*)

Derivatives—

Aldehyde, Ether, Ethyl acetate, Ethyl nitrite, and Paraldehyde.

Preparations containing alcohol—

Bitters, Brandies, Cordials, Elixirs, Essences, Fluidextracts, Spirits, Sirups, Tinctures, Tonics, Whiskies, and Wines.

MORPHINE, ALKALOID:

Derivatives—

Apomorphine, Dionine, Peronine, Morphine acetate, Hydrochloride, Sulphate, and other salts of morphine.

Preparations containing morphine or derivatives of morphine—

Bougies, Catarrh Snuff, Chlorodyne, Compound powder of morphine, Crayons, Elixirs, Granules, Pills, Solutions, Sirups, Suppositories, Tablets, Triturates, and Troches.

OPIUM, GUM:

Preparations of Opium—

Extracts, Denarcotized opium, Granulated opium, and Powdered opium, Bougies, Brown mixture, Carminative mixtures, Crayons, Dover's powder, Elixirs, Liniments, Ointments, Paregoric, Pills, Plasters, Sirups, Suppositories, Tablets, Tinctures, Troches, Vinegars, and Wines.

Derivatives—

Codeine Alkaloid, Hydrochloride, Phosphate, Sulphate, and other salts of codeine.

Preparations containing codeine or its salts—

Elixirs, Pills, Sirups, and Tablets.

COCAINE, ALKALOID:

Derivatives—

Cocaine hydrochloride, Oleate, and other salts.

Preparations containing cocaine or salts of cocaine—

Coca leaves, Catarrh powders, Elixirs, Extracts, Infusion of coca, Ointments, Paste pencils, Pills, Solutions, Sirups, Tablets, Tinctures, Troches, and Wines.

HEROIN:

Preparations containing heroin—

Sirups, Elixirs, Pills, and Tablets.

ALPHA AND BETA EUCAINE:

Preparations—

Mixtures, Ointments, Powders, and Solutions.

CHLOROFORM:

Preparations containing chloroform—

Chloranodyne, Elixirs, Emulsions, Liniments, Mixtures, Spirits, and Sirups.

CANNABIS INDICA:

Preparations of cannabis indica—

Corn remedies, Extracts, Mixtures, Pills, Powders, Tablets, and Tinctures.

CHLORAL HYDRATE (*Chloral*, U. S. Pharmacopœia, 1890) :*Derivatives—*

Chloral acetophenoximi, Chloral alcoholate, Chloralamide, Chloralimide, Chloral orthoform, Chloralose, Dormiol, Hypnal, and Uraline.

Preparations containing chloral hydrate or its derivatives—

Chloral camphorate, Elixirs, Liniments, Mixtures, Ointments, Suppositories, Sirups, and Tablets.

ACETANILIDE (*Antifebrine*, *Phenylacetamide*) :*Derivatives—*

Acetphenetidine, Citrophén, Diacetanilide, Lactophenin, Methoxy-acetanilide, Methylacetanilide, Para-Iodoacetanilide, and Phenacetine.

Preparations containing acetanilide or derivatives—

Analgesics, Antineuralgics, Antirheumatics, Cachets, Capsules, Cold remedies, Elixirs, Granular effervescing salts, Headache powders, Mixtures, Pain remedies, Pills, and Tablets.

Regulation 29. Statement of Weight or Measure.

(Section 8. Third under "Foods.")

(a) A statement of the weight or measure of the food contained in a package is not required. If any such statement is printed, it shall be a plain and correct statement of the average net weight or volume, either on or immediately above or below the principal label, and of the size of letters specified in Regulation 17.

(b) A reasonable variation from the stated weight for individual packages is permissible, provided this variation is as often above as below the weight or volume stated. This variation shall be determined by the inspector from the changes in the humidity of the atmosphere, from the exposure of the package to evaporation or to absorption of water, and the reasonable variations which attend the filling and weighing or measuring of a package.

Regulation 30. Method of Stating Quantity or Proportion.

(Section 8.)

In the case of alcohol the expression "quantity" or "proportion" shall mean the average percentage by volume in the finished product. In the case of the other ingredients required to be named upon the label, the expression "quantity" or "proportion" shall mean grains or minims per ounce or fluid ounce, and also, if desired, the metric equivalents therefore, or milligrams per gram or per cubic centimeter, or grams or cubic centimeters per kilogram or per liter; provided that these articles shall not be deemed misbranded if the maximum of quantity or proportion be stated, as required in Regulation 28 (d).

EXPORTS AND IMPORTS OF FOODS AND DRUGS.**Regulation 31. Preparation of Food Products for Export.**

(Section 2.)

(a) Food products intended for export may contain added substances not permitted in foods intended for interstate commerce, when the addition of such substances does not conflict with the laws of the countries to which the food products are to be exported and when such substances are added in accordance with the directions of the foreign purchaser or his agent.

(b) The exporter is not required to furnish evidence that goods have been prepared or packed in compliance with the laws of the foreign country to which said goods are intended to be shipped, but such shipment is made at his own risk.

(c) Food products for export under this regulation shall be kept separate and labeled to indicate that they are for export.

(d) If the products are not exported they shall not be allowed to enter interstate commerce.

Regulation 32. Imported Food and Drug Products.

(Section 11.)

(a) Meat and meat food products imported into the United States shall be accompanied by a certificate of official inspection of a character to satisfy the Secretary of Agriculture that they are not dangerous to health, and each package of such articles shall bear a label which shall identify it as covered by the certificate, which certificate shall accompany or be attached to the invoice on which entry is made.

(b) The certificate shall set forth the official position of the inspector and the character of the inspection.

(c) Meat and meat food products as well as all other food and drug products of a kind forbidden entry into or forbidden to be sold, or restricted in sale in the country in which made or from which exported, will be refused admission.

(d) Meat and meat food products which have been inspected and passed thru the customs may, if identity is retained, be transported in interstate commerce.

Regulation 33. Declaration.

(Section 11.)

(a) All invoices of food or drug products shipped to the United States shall have attached to them a declaration of the shipper, made before a United States consular officer, as follows :

I, the undersigned, do solemnly and truly declare that I am the _____ of the merchandise herein mentioned and described, and that it consists of food or drug products which contain no added substances injurious to health.

These products were grown in _____ and manufactured in _____ by _____ during the year _____, and are exported from _____ and consigned to _____. The products bear no false labels or marks, contain ^{no} _{some} added coloring matter or preservative _____, and are not of a character to cause prohibition or restriction in the country where made or from which exported.

Dated at _____ this _____ day of _____, 19 ____.

(Signed) : _____.

(b) In the case of importations to be entered at New York, Boston, Philadelphia, Chicago, San Francisco, and New Orleans, and other ports where food and drug inspection laboratories shall be established, this declaration shall be attached to the invoice on which entry is made. In other cases the declaration shall be attached to the copy of the invoice sent to the Bureau of Chemistry.

Regulation 34. Denaturing.

(Section 11.)

Unless otherwise declared on the invoice or entry, all substances ordinarily used as food products will be treated as such. Shipments of substances ordinarily used as food products intended for technical purposes must be accompanied by a declaration stating that fact, and must be so denatured as to prevent their use as foods.

Regulation 35. Bond, Imported Foods, and Drugs.

(Section 11.)

Unexamined packages of food and drug products may be delivered to the consignee prior to the completion of the examination to determine whether the same are adulterated or misbranded upon the execution of a penal bond by the consignee in the sum of the invoice value of such goods with the duty added, for the return of the goods to customs custody.

Regulation 36. Notification of Violation of the Law.

(Section 11.)

If the sample on analysis or examination be found not to comply with the law, the importer shall be notified of the nature of the violation, the time and place at which final action will be taken upon the question of the exclusion of the shipment, and that he may be present, and submit evidence, which evidence (Form 15), with a sample of the article, shall be forwarded to the Bureau of Chemistry at Washington, accompanied by report card (Forms 16, 17, 18, 19, and 20).

Regulation 37. Appeal to the Secretary of Agriculture and Remuneration.

(Section 11.)

All applications for relief from decisions arising under the execution of the law should be addressed to the Secretary of Agriculture, and all vouchers or accounts for remuneration for samples shall be filed with the chief of the inspection laboratory, who shall forward the same, with his recommendation, to the Department of Agriculture for action.

Regulation 38. Shipment beyond the jurisdiction of the United States.

(Section 11.)

The time allowed the importer for representations regarding the shipment may be extended at his request to permit him to secure such evidence as he desires, provided that this extension of time does not entail any expense to the Department of Agriculture. If at the expiration of this time, in view of the data secured in inspecting the sample and such evidence as may have been submitted by the manufacturers or importers, it appears that the shipment can not be legally imported into the United States, the Secretary of Agriculture shall request the Secretary of the Treasury to refuse to deliver the shipment in question to the consignee, and to require its reshipment beyond the jurisdiction of the United States.

Regulation 39. Application of Regulations.

These regulations shall not apply to domestic meat and meat food products which are prepared, transported, or sold in interstate or foreign commerce under the meat-inspection law and the regulations of the Secretary of Agriculture made thereunder.

Regulation 40. Alteration and Amendment of Regulations.

These regulations may be altered or amended at any time, without previous notice, with the concurrence of the Secretary of the Treasury, the Secretary of Agriculture, and the Secretary of Commerce and Labor.

The above rules and regulations are hereby adopted.

LESLIE M. SHAW,

Secretary of the Treasury.

JAMES WILSON,

Secretary of Agriculture.

VICTOR H. METCALF,

Secretary of Commerce and Labor.

WASHINGTON, D. C., October 17, 1906.

ADDITIONS AND CORRECTIONS, U. S. PHARMACOPOEIA (8th Rev.)

MAY 1st, 1907.

The passage of the National Food and Drugs Act, June 30, 1906, made the U. S. Pharmacopoeia (8th Rev.) the standard for official substances and forced a compliance with its requirements, and in consequence many communications were received by the Committee of Revision of the U. S. Pharmacopoeia requesting modifications in the official text. The following printed list of additions and corrections was issued May 1, 1907, and is inserted here, in order that the readers of the United States Dispensary may consult it with advantage.

Page 1viii insert ended 38 and also but not end

Products and Preparations Made on a Large Scale.

In the manufacture of products and preparations on the large scale, deviation from the official processes may be necessary, but the products must conform to the official requirements as determined by the tests of the U. S. Pharmacopoeia, 8th Revision, and the finished preparations must be identical with those made by the official processes.

Tests for Diluted Acids and Exsiccated Salts.—Where a requirement is made in official descriptions quoted from the U. S. Pharm. 8th Rev., that a diluted acid shall respond to the reactions and tests given under the corresponding stronger acid, or where similar language is employed, it is understood that the diluted acid shall be brought to the strength of the stronger acid before testing, or that the quantities used in testing the diluted acid be so adjusted that it will conform to the same standards as those established for the stronger acid. In the official descriptions of dried or exsiccated salts, where similar language is employed, it is understood that the exsiccated salt, before testing, shall have the proper allowance made for the water it has lost during the process of exsiccation.

Solubility Tests.—In the solubility tests quoted from the U. S. Pharm. 8th Rev., slight mechanical impurities, fragments of filter paper, fibre and minute traces of allowable insoluble impurities, permitted by other tests for the same substance, but which interfere with the transparency of the solution, are not to be construed as vitiating the test for solubility.

Page 9, line 32, 2nd col., insert "about" before "0.790" and in line 36, 2nd col., change "at 55.5° C. (132.3° F.)" to "from 55° to 57° C. (132.8° to 134.6° F.)"

Page 21, line 49, 1st col., change "121.4° C. (250.5° F.)" to "from 120° to 122° C. (245° to 251.6° F.)"

Page 24, lines 1, 2, 3, and 4, 1st col., change to "(1 in 20) should not at once become more than slightly cloudy after the addition of barium chloride T.S. (limit of sulphates); nor immediately more than opalescent by the addition of silver nitrate T.S. with nitric acid (limit of chlorides); it should not be precipitated by ammonium oxalate T.S. (absence of calcium);"

Page 27, omit lines 11 to 15, 2nd col., inclusive, and lines 59 to 63, 2nd col., inclusive, change from "No." to "iron." inclusive, to read: "No. 121, omitting the subsequent addition of ammonia water." Line 56, 2nd col., change "10" to "20"

Page 29, line 58, 2nd col., change "83.7" to "from 83 to 86"

Page 31, lines 44, 45, and 46, 1st col., change "Barium" to "acid" inclusive, to "Ten Cc. of the Acid should not be rendered more than slightly cloudy by the addition of 1 Cc. of barium chloride T.S. (limit of sulphuric acid)" Line 52, 1st col., change "1" to "8.3"

Page 33, lines 21 and 22, 2nd col., replace by "Ten Cc. of the Acid should not be rendered more than slightly cloudy by the addition of 1 Cc. of barium chloride T.S. (limit of sulphuric)"

Page 45, lines 22 to 30 inclusive, 2nd col., from "If" to "acids," inclusive, replace by "If 10 Cc. of the Acid be neutralized with ammonia water, not more than a slight precipitate should result, and after filtering, the filtrate should not become turbid upon the addition of potassium sulphate T.S. (limit of barium)."

Page 48, line 18, 2nd col., after "trazilation" insert "at boiling temperature" Line 54, 1st col., change "10" to "20"

Page 57, line 5, 2nd col., change "about 4° C. (39.2° F.)" to "from 9° to 4° C. (48.2° to 39.2° F.)" Line 14, 2nd col., change "the ordinary temperature" to "25° C. (77° F.)"

Page 59, lines 47 and 48, 2nd col., omit "barium chloride T.S. (absence of sulphuric acid), or by" Line 55, 2nd col., between "acids," and "If" insert: "If 0.1 Cc. of the Acid be diluted with water to 7 Cc. and 1 Cc. of barium chloride T.S. be added, no cloudiness or precipitate should appear within 30 seconds (limit of sulphuric acid)." Line 58, 2nd col., change "10 Cc. of a cold saturated solution of sodium chloride" to "a cold, saturated aqueous solution, containing 5 Gm. of sodium chloride"

Page 63, line 19, 2nd col., change "potassium" to "sodium"

Page 76, line 2, 1st col., change "several minutes," to "four hours."

Page 80, 2nd col., bottom line and Page 81, 1st col., lines 1, 2 and 3, from "Soluble" to "alcohol," inclusive, change to "Very soluble in water and alcohol at 25° C. (77° F.), and in boiling water and boiling alcohol;"

Page 81, line 10, 1st col., change "0.2" to "0.6"

Page 84, line 19, 1st col., change "135° C. (275° F.)" to "from 158° to 170° C. (334.4° to 338° F.)"

Page 85, line 18, 1st col., change "remain unaffected" to "show but a faint turbidity" and Line 19, 1st col., change "absence," to "limit" Line 30, 1st col., change "10" to "20"

Page 92, 1st col., line 34, change "Hematoxylin" to "Cochineal" Line 52, change "10" to "25" Line 55, change "40" to "25" Second col., line 3, change "hematoxylin" to "cochineal" Line 6, change "violet" to "pink" Lines 7, 8 and 9, omit "the transition stages being as follows: first yellow, then green, finally passing into violet."

Page 101, line 28, 1st col., change "0.885" to "0.895" Line 29, 1st col., change "7" to "9" Line 32, 1st col., change "about 72° C. (161.6° F.)" to "from 72° to 77° C. (161.6° to 170.6° F.)"

Page 102, line 23, 2nd col., change "0.918" to "0.911 to 0.916"

Page 117, lines 34 to 39 inclusive, 2nd col., from "Aloin" to "F." inclusive change to "Aloin from Curacao Aloes is almost completely soluble in 120 parts of water, 15 parts of alcohol, and 55 parts of acetone." Lines 39 to 42 inclusive, 2nd col., omit from "The" to "F."

Page 121, lines 27 to 30 inclusive, 2nd col., omit from the word "and" to "alum." Line 37, 1st col., change "20" to "150"

Page 123, line 60, 2nd col., after "acid" insert "and 130 Cc. of water"

Page 125, 1st col., line 23, change "10" to "20" Line 30, change "20" to "150"

Page 128, line 29, 1st col., change "25" to "28"

Page 129, line 59, 1st col., change "100" to "150"

Page 133, 1st col., line 3, change "2" to "3" and "50" to "80" Line 7, omit "completely" Lines 31 and 32, change "more strongly heated, should be volatilized (absence) to "Ignited should yield not more than 0.0005 Gm. of non-volatile residue (limit)" Line 24, 1st col., change "20" to "150"

Page 134, line 29, 2nd col., change "100" to "150"

Page 140, lines 58 and 59, 2nd col., omit sentence beginning "It boils"

Page 148, line 16, 2nd col., after "(230° F.)" insert "in a vacuum"

Page 149, line 8, 1st col., change "Two Gm." to "If 0.1 Gm." Line 9, 1st col., change the word "when" to "be" Line 10, 1st col., insert before "should" the words "the solution"

Page 159, line 60, 2nd col., omit "and melts at 263° C. (507° F.)"

Page 170, lines 2 to 10 inclusive, 1st col., from "On" to "substances," inclusive, change to "If 0.1 Cc. of tenth-normal potassium permanganate V.S. be added to 10 Cc. of ammonia water, which has been slightly supersaturated with diluted sulphuric acid, the pink color should not be completely destroyed within ten minutes (limit of readily oxidizable substances)." Omit lines 10 to 14 inclusive, 1st col., from "If" to "acid."

Page 177, line 56, 2nd col., change "0.075" to "0.050"

Page 180, lines 35 and 36, 1st col., omit "to" and "1 Cc. of ammonia water be added and the mixture"

Page 189, lines 8 and 9, 2nd col., change "no residue should be left (absence of foreign salts)." to "not more than 0.1 percent. of residue should remain (limit of foreign salts)."

Page 193, line 40, 1st col., omit "and completely" and line 42, omit "or chloride" and insert before the word "When": "If 0.2 Gm. of the Oxide be dissolved in a mixture of 1 Cc. of nitric acid and 2 Cc. of distilled water, 10 Cc. of ammonia water added, and the liquid diluted to 60 Cc., then 10 Cc. of this solution should not immediately become cloudy upon the addition of 1 Cc. of nitric acid (limit of chloride)."

Page 197, lines 10 and 11, 2nd col., change "has a yellow color, is neutral to litmus paper" to "should be colorless to yellow"

Page 208, line 38, 2nd col., change "10" to "15"

Page 225, line 42, 2nd col., change "0.35" to "0.3"

Page 226, line 14, 1st col., change "0.5" to "0.45"

Page 228, line 13, 1st col., change "Hematoxylin" to "Cochineal" Line 59, change "hematoxylin" to "cochineal"

Page 229, line 44, 2nd col., change "phenolphthalein" to "rosolic acid" Lines 54 and 55, 2nd col., change "phenolphthalein" to "rosolic acid"

Page 237, line 47, 2nd col., change "58" to "56" and "60" to "58"

Page 238, lines 29 and 30, 1st col. omit "and permanent in the air," Lines 44 to 49, 1st col., to the word "nitrate," inclusive, replace by "If 0.01 Gm. of the salt be mixed with 1 Cc. of water, 5 Cc. of sulphuric acid added, the mixture cooled and then 5 Cc. of ferrous sulphate T.S. carefully poured over it, without mixing, no red or brown zone should appear within 5 minutes (limit of nitrate)." Line 3, 2nd col., change "0.58" to "0.56" Line 4, 2nd col., change "0.6" to "0.58" Line 14, 2nd col., change "48" to "46 percent, nor more than 50"

Page 238, three bottom lines, 2nd col., and—

Page 239, lines 1 to 4, 1st col., inclusive, replace by "If 0.01 Gm. of the salt be dissolved in 1 Cc. of water, 5 Cc. of sulphuric acid added, the mixture cooled and then 5 Cc. of ferrous sulphate T.S. carefully poured over it, without mixing, no red or brown zone should appear within 5 minutes (limit of nitrate)." Line 24, change "0.48" to "0.46 Gm., nor more than 0.50"

Page 241, line 29, 2nd col., after "acid" insert "and" Line 30, 2nd col., change "added, and this mixture" to "the mixture filtered, and the filtrate"

Page 243, lines 58 and 59, 2nd col., change "2.990 to 3.000 at 15° C. (59° F.)," to "about 3.016 at 25° C. (77° F.)." Line 59, 2nd col., after "Boiling point," insert "about"

Page 244, line 38, 2nd col., change "64" to "66"

Page 245, 2nd col., line 4, change "five minutes" to "one minute" Line 5, change "absence" to "limit" Line 17, change "0.2" to "0.05" Line 18, change "0.3" to "0.1" Line 36, change "0.64" to "0.66"

Page 247, line 30, 1st col., change "a" after "produce" to "more than a slight" Line 31, change "absence" to "limit"

Page 253, line 34, 1st col., insert before "Its" "when dried at 100° C. (212° F.), to constant weight."

Page 257, lines 58 to 61, 1st col., from "Soluble" to "tures," inclusive, change to "Very soluble in water and alcohol."

Page 258, line 63, 1st col., change "absence" to "limit"

Page 259, 1st col., line 10, change "absence" to "limit" Line 14, change "a trace" to "0.1 percent."

Page 260, lines 4 to 8, 2nd col., from "The" to "acid," inclusive, change to "The aqueous solution (1 in 20) yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid. One Gm. of the salt dissolved in 20 Cc. of water, should not require the addition of more than 1 Cc. of tenth-normal potassium hydroxide V.S. to produce a pink color (phenolphthalein being used as indicator)."

Page 261, lines 56 and 57, 2nd col., change "Two Gm. of Calcium Phosphate" to "Five Cc. of a solution (1 in 10) of Calcium Phosphate, in diluted hydrochloric acid"

Page 270, line 48, 2nd col., change "60" to "55"

Page 271, 1st col., line 50, change "2.08" to "1.9" Line 57, change "60" to "55"

Page 318, 1st col., line 22, change "0.938" to "0.935" Line 24, change "45" to "42" and "113" to "107.6"

Page 324, 2nd col., line 61, after "Chloral" insert "(1 in 20)" Line 65, before "acidulated" insert "slightly"

Page 325, lines 2 to 9, omit from "If" to "alcoholate)."

Page 327, line 41, 1st col., change "glass" to "well."

Page 331, line 23, 1st col., change "twenty" to "five"

Page 357, 2nd col., line 38, change "200" to "400" Line 39, change "125" to "250" change "25" to "50" Line 51, change "100" to "200"

Page 363, 2nd col., line 36, before "solidify," insert "partially" Line 54, change "phenolphthalein" to "rosolic acid" Line 64, change "phenolphthalein" to "rosolic acid"

Page 371, line 52, 1st col., change "Hematoxylin" to "Cochineal" Line 30, 2nd col., change "hematoxylin" to "cochineal"

Page 378, line 5, 2nd col., change "88" to "120"

Page 380, line 13, 2nd col., before "is" insert "(1 in 20)" and before "to" insert "or faintly acid"

Page 381, line 6, 1st col., change "0.58" to "0.45"

Page 384, line 23, 1st col., change "nitric" to "hydrochloric"

Page 399, 1st col., line 33, change "2.8" to "3.2" Line 38, change "4 drops" to "1 drop" Line 39, change "1 Cc." to "3 Cc."

Page 403, line 23, 1st col., change "1.072" to "1.078" Lines 13 to 17, 2nd col., from "On" to "oils," change to "Two Cc. of Cresote should require not less than 10 Cc., nor more than 18 Cc. of normal sodium hydroxide V.S. to produce a clear, pale yellow liquid, which remains unclouded on diluting with 50 Cc. of water (absence of neutral oils)."

Page 406, 1st col., line 22, insert "from 1.036 to 1.0" Line 27, change "It boils from" to "When distilled, 90 percent. of the Cresol should boil between" Lines 32 to 37, omit from "If" to "phenol," inclusive.

Page 413, line 27, 2nd col., before "a" insert "and ignition"

Page 438, line 60, 1st col., change "Hematoxylin" to "Cochineal" Line 39, 2nd col., change "hematoxylin" to "cochineal"

Page 454, line 29, 1st col., change "0.925" to "from 0.921 to 0.923"

Page 470, line 33, 2nd col., change "Hematoxylin" to "Cochineal"

Page 471, line 14, 1st col., change "hematoxylin" to "cochineal"

Page 486, line 38, 1st col., after "Erlenmeyer flask," insert "add a little more sand to the dish and, by rubbing, remove any adherent extract, which transfer to the flask."

Page 488, 1st col., lines 50 and 55, change "1.4" to "1.0"

Page 493, lines 2 to 10, 2nd col., from "If" to "bonate," inclusive, change to "If 1.15 Gm. of Saccharated Ferrous Carbonate be dissolved in 10 Cc. of diluted sulphuric acid (1 to 5) and the solution diluted with water to about 100 Cc. it should require not less than 15 Cc. of tenth-normal potassium dichromate V.S. for complete oxidation, potassium ferriyanide T.S. being used as indicator (corresponding to not less than 15 percent. of ferrous carbonate)."

Page 498, line 43, 1st col., change "a slightly" to "an"

Page 499, line 14, 1st col., change "neutral" to "acid"

Page 511, 1st col., line 30, change "2" to "8" Line 32, change "1" to "2"

Page 519, line 14, 2nd col., after "acid" insert "in a test-flask (see page 1707)."

Page 520, 1st col., line 11, change "slowly add" to "add a few drops of starch T.S. followed by" Line 12, before "with" insert "added slowly," Lines 12 and 13, change "last trace of brown color" to "blue or greenish color"

Page 526, 1st col., line 47, change "Hematoxylin" to "Cochineal" Line 54, change "10" to "25" Line 56, change "40" to "25" Second col., line 12, change "hematoxylin" to "cochineal" Line 14, change "violet" to "pink" Lines 15 to 17, omit "the transition stages being as follows: first yellow, then green, finally passing into violet."

Page 528, 1st col., line 32, change "0.5" to "0.4" Line 40, change "Hematoxylin" to "Cochineal" Second col., lines 6 and 7, change "hematoxylin" to "cochineal"

Page 533, line 57, 1st col., change "120° C. (248° F.)" to "110° C. (230° F.)"

Page 534, line 43, 2nd col change "Hematoxylin" to "Cochineal"

Page 535, line 15, 1st col., change "hematoxylin" to "cochineal" Line 31, change "0.5" to "0.4"

Page 546, 2nd col., line 2, change "1.75" to "1.5" Line 9, change "Hematoxylin" to "Cochineal" Line 15, after "V.S." insert "and 20 Cc. of distilled water" Line 39, change "hematoxylin" to "cochineal" Lines 41 to 43, change "to just cause the yellow color of the solution to turn purple" to "until a pink color is produced"

Page 564, line 57, 1st col., change "0.35" to "0.25"

Page 603, 1st col., line 11, change "1.140" to "from 1.110 to 1.114" Line 21, before "Turbidity" insert "Permanent" Line 24, change "7 Cc. of sodium hydroxide T. S." to "2 Cc. of potassium hydroxide solution (5 percent.)" Line 26, insert "nearly" before "white mass," and insert "Much" before "Coloration" Line 27, omit "white" Lines 29 to 33, omit from "One" to "creosote," inclusive.

Page 624, line 48, 2nd col., after "evaporation" insert "and gentle ignition"

Page 625, line 55, 2nd col., change "99.5" to "98.5"

Page 629, line 48, 2nd col., change "no appreciable" to "not more than 0.05 percent. of"

Page 633, lines 12 to 14, 1st col., from "and" to "solutions," inclusive, change to "soluble in diluted nitric acid, forming a clear solution, or in hydrochloric acid (1 in 10) with faint opalescence."

Page 639, lines 39 to 43, 1st col., from "If" to "oxide," inclusive, change to "If 0.1 Gm. of the powder be digested with 20 Cc. of warm diluted hydrochloric acid, the filtrate should not be affected by hydrogen sulphide T.S. (limit of mercuric oxide)."

Page 645, 2nd col., line 33, change "179.7° C. (355.5° F.)" to "from 191° to 192° C. (375.8° to 377.6° F.)" Line 62, change "no" to "but a faint yellow"

Page 647, 1st col., lines 26 to 30, change to "white prismatic crystals having an acid, nauseous, and bitter taste; deliquescent on exposure to the air." Line 61, change "no" to "but a faint yellow"

Page 660, line 34, 2nd col., change "0.1" to "0.2"

Page 667, line 33, 2nd col., change "2" to "1.75"

Page 674, 2nd col., line 21, change "Hematoxylin" to "Cochineal" Line 64, change "hematoxylin" to "cochineal"

Page 675, 2nd col., line 46, change "8" to "7" Line 46, change "but not more than 1.5 percent. of resin" to "of which not more than 15 percent. should be"

Page 714, line 14, 2nd col., change "about 1.282" to "from 1.280 to 1.290"

Page 719, line 36, 2nd col., change "about 1.432" to "from 1.430 to 1.450"

Page 720, line 47, 1st col., change "cool" to "moderately warm" Line 50, 2nd col., change "1.075 to 1.078" to "from 1.075 to 1.081"

Page 721, 1st col., lines 13 and 14, from "should" to "impurities," inclusive, change to "should leave not more than 0.05 percent. of residue (limit of fixed impurities)" Line 18, change "0.5" to "1" Line 19, change "0.1" to "0.2" Second col., line 43, change "ten" to "thirty"

Page 742, line 4, 2nd col., change "absence" to "limit"

Page 743, line 48, 1st col., change "absence" to "limit"

Page 744, line 12, 2nd col., change "absence" to "limit"

Page 745, 2nd col., lines 21 and 22, change "is neutral" to "(1 in 20) is faintly alkaline" Line 45, omit "anhydrous" After "Citrate" insert "dried at 150° C. (302° F.)" Line 60, change "absence" to "limit"

Page 746, line 41, 2nd col., change "slightly reddens blue" to "(1 in 20) should be neutral or slightly acid to"

Page 747, line 24, 1st col., change "absence" to "limit"

Page 752, line 61, 1st col., change "0.001" to "0.01" Line 6, 2nd col., after "acid" insert "and 130 Cc. of water"

Page 754, 2nd col., line 46, change "0.005" to "0.04" Line 60, after "acid" insert "and 100 Cc. of water"

Page 757, line 38, 1st col., change "0.85" to "1.1"

Page 761, line 8, 2nd col., change "neutral" to "acid"

Page 763, 1st col., line 11, change "20" to "100" Line 15, change "absence" to "limit"

Page 779, 1st col., lines 9 to 13 inclusive, omit "a bulky, white, crystalline precipitate will be produced; then, if the test-tube, loosely corked, be allowed to stand in boiling water for about five minutes, with occasional agitation, the precipitate should dissolve, and form" Line 14 after "solution" insert "should result"

Page 786, 1st col., line 12, after "heated" insert "slowly" Line 14, change "then" to "when heated rapidly it" Line 65, omit "colorless"

Page 792, lines 4 and 5, 1st col., omit "and the remaining two at 130° C. (266° F.)."

Page 833, 2nd col., line 40, change "0.985" to "0.988" Line 41, after "being" insert "up to"

Page 839, line 20, 1st col., change "0.905 to 0.915" to "0.900 to 0.910"

Page 841, lines 18 to 23, 1st col., omit from "Specific" to "F.)"

Page 843, line 7, 2nd col., omit "Soluble in 2 volumes of alcohol."

Page 844, line 54, 2nd col., change "about +50°" to "not below +45°"

Page 846, line 59, 1st col., change "—5° C. (23° F.)" to "—3° C. (26.6° F.)"

Page 849, lines 48 and 49, omit from "Soluble" to "alcohol," inclusive.

Page 850, line 61, 2nd col., change "0.880 to 0.892" to "0.875 to 0.910"

Page 851, 2nd col., line 24, change "+ 60°" to "+ 58°" Lines 40 and 41, change "phenolphthalein" to "rosolic acid" Line 51, change "phenolphthalein" to "rosolic acid"

Page 853, line 19, 2nd col., change "8" to "6"

Page 854, line 11, 1st col., change "—25°" to "—20°"

Page 868, 2nd col., line 36, change "180" to "183" Line 47, change "86" to "84"

Page 872, 1st col., line 29, change "5" to "2.5" Line 31, change "15" to "10"

Page 875, lines 40, 41 and 42, 2nd col., omit from "Soluble" to "paper," inclusive.

Page 886, 2nd col., line 6, change "212 to 218" to "203 to 215" Line 17, change "102" to "103" and "105" to "109"

Page 903, line 32, 2nd col., change "six" to "sixteen" and omit "or over night"

Page 911, line 25, 1st col., after "percentage" insert "powdered sugar of milk or acacia"

Page 912, line 39, 1st col., after "test-tube" insert "diluted with three times its volume of water," Line 35, 2nd col., change "120" to "200" Line 47, 2nd col., change "2" to "4"

Page 915, 1st col., line 33, change "123° C." to "121° C." Line 34, change "253.4" to "249.8"

Page 924, lines 26 to 33, 1st col., omit from "If" to "impurities," inclusive.

Page 927, 2nd col., line 5, change "40° C. (104° F.)" to "39° C. (102.2° F.)" Lines 5 to 9, from "Phenol" to "Phenol," inclusive, change to "Phenol should have a boiling point from 178° to 182° C. (352.4° to 359.6° F.)." Line 48, omit "which is permanent."

Page 965, line 22, 2nd col., omit "0.1 Gm. of"

Page 967, line 7, 2nd col., change "soluble in" to "miscible with" and omit "or solutions of potassium or sodium hydroxide"

Page 969, 2nd col., lines 23 to 25, from "be" to "iron," inclusive, change to "upon the addition of ammonia water yield more than a slight precipitate (limit of zinc and iron)." Lines 26 and 27, change "should leave no residue (absence)" to "should not leave more than a slight residue (limit)"

Page 974, 1st col., line 22, after "salt" insert "(1 in 10)" Lines 26 to 28, from "be" to "iron," inclusive, change to "yield more than a slight precipitate upon the addition of ammonia water (limit of zinc and iron)" Line 30, change "a weighable" to "more than a slight"

Page 1003, line 28, 1st col., after "white" insert "or nearly white"

Page 1005, line 22, 1st col., before "The" insert "One Gm. of the dried salt, dissolved in about 10 Cc. of water should not require more than 1.5 Cc. of tenth-normal hydrochloric acid v.s. for neutralization (methyl orange T.S. being used as indicator)."

Page 1014, lines 25 to 31, 2nd col., from "If" to "V.S." inclusive, change to "If 0.1 Gm. of Potassium Permanganate be dissolved in 100 Cc. of distilled water, to which 1 Cc. of sulphuric acid and 35 Cc. of tenth-normal oxalic acid V.S. have been previously added, then the addition of not more than 3.5 Cc. of tenth-normal potassium permanganate V.S. should be required to impart a permanent pink tint."

Page 1046, lines 6 to 31, 1st col., change the "Test for Other Cinchona Alkaloids" to read: "Dry Quinine Sulphate at 50° C. (122° F.) for two hours. If 1.8 Gm. of this Dry Quinine Sulphate (which should be neutral or slightly alkaline to test paper) be agitated with 20 Cc. of water, at 55° C. (149° F.) for half an hour, then allowed to cool to 15° C. (59° F.) and be macerated at this temperature for two hours, with occasional shaking of the test tube, the liquid filtered through filter paper of 8 to 10 Cm. diameter, then if 5 Cc. of the filtrate be transferred to a test-tube, and gently mixed (without shaking) with 7 Cc. of ammonia water which must be of official strength, have a temperature of 15° C. (59° F.), and be all added at once, a clear liquid should be produced. If the temperature during the maceration has been 16° C. (60.8° F.) 7.5 Cc. of ammonia water may be added. If 17° C. (62.8° F.), 8 Cc. may be added (limit of allowable foreign cinchona alkaloids)."

Page 1052, line 25, 1st col., change "10" to "15"

Page 1053, line 54, 1st col., change "110" to "109" and "230" to "228.2"

Page 1055, lines 10 to 13, 1st col., omit from "Sulphuric" to "rosin," inclusive.

Page 1077, lines 11 to 18, 2nd col., from "If" to "sugar," inclusive, change to "If 1 Gm. of Sugar of Milk be digested for half an hour with 10 Cc. of diluted alcohol, with occasional shaking, and the liquid filtered, the filtrate should remain clear after admixture with an equal volume of absolute alcohol, and this liquid, if evaporated on a water-bath, should leave not more than 0.03 Gm. of residue (absence of cane sugar)." Line 19, 2nd col., change "10" to "20"

Page 1130, line 22, 1st col., change "36.9" to "36.5"

Page 1133, line 48, 1st col., change "20.4" to "17"

Page 1146, lines 4 to 7, 1st col., from "dry" to "odorless," inclusive, change to "Dry, white or nearly white flakes, powder, fused masses or translucent or opaque white pencils, odorless,"

Page 1147, line 49, 1st col., between the words "paper" and "The" insert "One Gm. of the dried salt, dissolved in about 10 Cc. of water, should not require more than 1.5 Cc. of tenth-normal hydrochloric acid V.S. for neutralization (methyl-orange T.S. being used as indicator)."

Page 1150, line 50, 1st col., after "white" insert "or nearly white"

Page 1152, lines 30 to 32, 2nd col., from "No" to "etc.," inclusive, change to "Not more than a slight turbidity should appear on dissolving 1 Gm. of the salt in 20 Cc. of water (limit of calcium, aluminum, etc.)."

Page 1154, line 18, 1st col., between the words "and" and "conforms" insert "which, after allowance is made for the loss of 60.3 percent, of water of crystallization,"

Page 1157, line 25, 2nd col., change "96" to "94"

Page 1158, lines 24 to 26, 1st col., change "the solution allowed to stand for about one hour, and shaken at frequent intervals, not more than 11.65 Cc. of tenth-" to "and after solution has taken place, not more than 12.45 Cc. of tenth-"

Page 1166, 1st col., line 16, change "the original" to "one-tenth the" Line 17, after "Ether" insert "taken."

Page 1179, lines 29 to 34, 2nd col., omit from "If" to "coloring," inclusive.

Page 1184, line 50, 1st col., change "0.35" to "0.25" Line 20, 2nd col., insert after "deliquescent" and also occasionally efflorescent"

Page 1185, line 55, 1st col., after "plates" "insert" or white granular powder, or crystalline crusts"

Page 1191, lines 58 and 59, 2nd col., change "should not produce more than a faintly pink color" to "may produce a yellow but not a red or reddish color"

Page 1196, lines 11 and 12, 1st col., change "should not produce more than a faintly yellow color" to "may produce a yellow but not a red or reddish color" Lines 37 and 38, 2nd col., change "should not produce more than a faintly yellow color" to "may produce a yellow but not a red or reddish color"

Page 1198, line 19, change "70" to "50" Line 23, change "insoluble" to "partially soluble"

Page 1201, line 38, 1st col., after "crystals" insert "or crystalline powder"

Page 1224, line 26, 1st col., after "green" insert "or yellowish green"

Page 1242, 1st col., line 5, change "about 0.850" to "From 0.860 to 0.865" Lines 7 and 8, change "155" to "165" C. (311" to 329° F.) to "160" to 170° C. (320" to 338° F.)" Line 17, omit "very"

Page 1251, line 52, 1st col., before "45" insert "when dried over sulphuric acid" Second col., line 42, change "0.5" to "0.1" Line 43, change "10" to "20" Lines 46 and 47, change "(absence of iodides)" to "(limit of halogen salts)"

Page 1255, line 58, 2nd col., change "0.035" to "0.05"

Page 1263, line 36, 2nd col., change "0.05" to "0.04"

Page 1287, line 63, 2nd col., change "0.03" to "0.025"

Page 1349, line 7, 2nd col., after "white" insert "or nearly white"

Page 1351, line 18, 2nd col., after "white" insert "or nearly white"

Page 1353, line 30, 1st col., after "white" insert "or nearly white"

Page 1354, line 5, 1st col., change "100.5" to "100" Line 22, change "5.4" to "5.3" Line 26, change "about 4" to "4.04"

Page 1369, line 23, 2nd col., change "remain clear" to "show but a faint cloudiness"

Page 1713, line 60, insert reference to following foot-note "1" after "(1 in 20)," and the following foot-note at bottom of page: "The dilution (1 in 20) has been extended, except as stated below, by the Committee of Revision to a total dilution of 1 in 100; for iron the total dilution is extended to 1 in 300. Exception: For chemical substances to be tested for antimony, arsenic and lead, the dilution has not been extended, but remains at 1 in 20." Line 69, after "viewed" insert "crosswise"

Page 1715, after line 50, insert "131a. Rosolic Acid Test Solution. Dissolve 1 Gm. of commercial rosolic acid (chiefly methylaurin, C₂₀H₁₄O₆) in 10 Cc. of diluted alcohol, and add enough water to make 100 Cc. Of this solution, about 0.5 Cc. is used for 100 Cc. of solution to be titrated. Ammoniacal solutions should be highly diluted when titrated with this indicator. In place of rosolic acid, commercial praeonin (aurin E) may be employed. This indicator gives a yellow color with acids and violet-red with alkalis."

Page 1728, line 10, insert reference to following foot-note "1" after "solvent" and the following foot-note at bottom of page: "If extraction is incomplete, the processes must be repeated with additional solvent. The completion of the 'shaking out' processes may be tested by evaporating a small portion of the solution, dissolving the residue in acidulated water and adding mercuric potassium iodide T.S., when the absence of turbidity indicates exhaustion." Line 23, after "not" insert "strongly" Before "hematoxylin" insert "either"

Page 1757, above line 15 from bottom insert "In the alcohol tables the words 'abs. alc.' (absolute alcohol), mean 100 percent, alcohol, not the official, (99 percent.) absolute alcohol."

THE DISPENSATORY

OF

THE UNITED STATES

PART I

THE United States Dispensatory may very properly be considered as a commentary upon the United States and British Pharmacopœias, while such preparations of the German Pharmacopœia and French Codex as are used generally in the United States are also commented upon. As was explained in the fifteenth edition, the changes in the arrangement of the 1880 edition of the United States Pharmacopœia necessitated corresponding alterations in the United States Dispensatory. PART I. of the present volume contains the discussion of all the remedies recognized by either of the two Pharmacopœias used by English speaking people. In PART II. non-official drugs and preparations are treated, as heretofore, by themselves; the type is smaller than that used for official substances, it being deemed judicious to adhere to a plan which has given so much satisfaction in the previous editions. In PART III. are considered the Tests and Test-Solutions of the two Pharmacopœias, Weights and Measures, the Art of Prescribing Medicines, and cognate miscellaneous matters.

There can be no question as to the superiority of the alphabetical arrangement of drugs in a book of reference of an encyclopedic character. Their scientific classification belongs to works which treat of them rather in their relations than their essential properties; and different systems have been adopted, according to the set of relations towards which the mind of the author has been especially directed. Thus, the naturalist classifies them according to the affinities of the several objects in nature from which they are derived; the chemist, according to their composition; the practitioner of medicine, according to their effects upon the system in a state of health and disease.

ACACIA. U. S. (Br.)

ACACIA [Gum Arabic]

(a-câ'cî-a)

"A gummy exudation from *Acacia Senegal* Willdenow, and other species of *Acacia* (Fam. *Leguminosæ*)." U. S. "A gummy exudation from the stem and branches of *Acacia Senegal*, Willd., and of other species of *Acacia*, Willd." Br.

Acaciæ Gummi, Br.; Gummi Africanum; Gummi Mimosæ; Gum Acacia; Galam Gum; Gomme Arabique Vraie, Fr.; Gummi Arabicum, P. G.; Arabisches Gummi, G.; Gomma Arabica, Gomma del Cordofan, It.; Goma Arabiga, Sp.; Samagh Arabee, Arab.

For ACACIÆ CORTEX, Br. Add., see PART II. The name *Acacia* was employed by the ancient Greeks to designate the gum tree of Egypt, and has been appropriately applied to the genus in which that plant is included.

The most important of the gum yielding *Acacias* are *A. arabica*, Willd., and the official *A. Senegal*, Willd.

A. Senegal, Willdenow. *A. Verek*, Guillemin and Perottet, *Flore de Sénégambie*, 1830, 246; B. & T. 1877. *Mimosa Senegal*, L.—This is a small tree with a grayish bark, the inner layers of which are strongly fibrous, bipinnate leaves, dense spikes of small yellow flowers longer than the leaves, and broad pods 3 to 4 inches long, containing 5 or 6 seeds. It rarely exceeds 20 feet in height, forms large forests in Western Africa, north of the river Senegal, and is abundant in Eastern Africa, Kordofan, and Southern Nubia. It is known by the natives as *Verek* or *Hashab*.

Acacia arabica, Willd., *Sp. Plant.* iv. 1805. *A. vera*, Willd.; Hayne, *Darstel. und Beschreib.* x. 34. *Acacia nilotica*, Del., *Illust. Flor. de l'Égypte*, p. 79. *A. Adansoni*, Guill. & Per., *Flore de Sénégambie*. *A. Verek*, Ibid.—This is a tree of middle size. The leaves are alternate and bipinnate, with two pairs of pinnae, of which the lower are usually furnished with ten pairs of leaflets, the upper with eight. The leaflets are very small, oblong-linear, smooth,

and supported upon very short footstalks. On the common petiole is a gland between each pair of pinnæ. Both the common and partial petioles are smooth in typical specimens of *A. vera*, Willd., but in the form originally described by Willdenow as *A. arabica* are downy; by most botanists the distinction is not thought sufficient to be specific. The flowers are yellow, inodorous, small, and collected in globular heads, supported upon slender peduncles which rise from the axils of the leaves, in number from two to five together. The fruit is a smooth, flat, two-valved legume, divided, by contractions occurring at regular intervals, into several roundish portions, each containing one seed. This species flourishes in Southern Nubia, Egypt, and Senegal, and is probably scattered over the whole intervening portions of Africa; it is also abundant in Hindostan.

Besides the species above described, the following afford considerable quantities of gum:—*A. horrida*, Willd. (*A. Karroo*, Hayne), of the Cape of Good Hope; *A. spirocarpa*, Hochst. (*A. gummifera*, Del.), seen by Broussonet in Morocco near Mogador; *A. ehrenbergiana*, Hayne, a shrub six or eight feet high, named in honor of the German traveller Ehrenberg, who observed it in the deserts of Libya, Nubia, and Dongola; *A. Seyal*, Del. (*A. fistula*, Schweinfurth), growing in the same region, and also in upper Egypt and Senegambia; and *A. tortilis*, Hayne, which attains the height of sixty feet, and inhabits Arabia Felix, Nubia, Dongola, and the Libyan Desert; these are all said to contribute to Senegal gum. According to Schweinfurth, *A. stenocarpa*, Hochst., yields the brownish gum of the Soudan sometimes known as the "*taleh*" gum.¹ *A. glaucophylla*, Steud., of the mountains of Abyssinia, is said to yield a gum, as do also various Australian acacias.

The gum bearing acacias are all hard-wooded, more or less thorny trees, usually small and dwarfish in the dry sandy soil of desert regions, but along river banks and other moist places becoming luxuriant and beautiful.

The bark and unripe fruit of the acacia contain both tannic and gallic acids. The dried juice of the pod was used by the ancient Greeks; and an extract is still sold in the bazaars of India under the name of *Akakia*. This extract is heavy, hard, of an agreeable odor, varying in color from greenish to dark-reddish, or when seen in bulk, blackish. It has a sweet, astringent taste, and yields a mucilaginous infusion. A similar preparation, *acacia nostras*, has been prepared in Europe by expression and inspissation from the unripe fruit of *Prunus spinosa*, or wild plum tree.

The gum of the acacias exudes spontaneously from the bark, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. The gum is said also to be

found immediately under the bark, where it is sometimes collected in regular cavities. It is probably due to changes produced in starch and cellulose by a peculiar species of bacterium.² It is stated by Jackson that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential, for in cooler climates, though the tree may flourish, it yields no gum. It is probable that some species of acacia yield finer gum than others, but it is also certain that the same tree will often yield some gum of the finest quality in regular tears or globular masses, and some irregular shaped, dark colored fragments of inferior value. Thus, from the same tree it will exude frothy or thick, and clear or dark colored, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce. Schweinfurth and other observers state, however, that the finest gum is obtained only from the *A. vera*, and perhaps one or two other species.

Commercial History and Varieties.—The most common varieties of this drug are the *Turkey* or *Egyptian*, the *Barbary*, the *Senegal*, and the *India gums*.

TURKEY GUM. (*Egyptian Gum*).—Gum arabic formerly entered commerce almost exclusively through Egypt, being collected in Upper Egypt, Nubia, Kordofan, Darfur, and other regions of the Upper Nile, and carried to Alexandria, from whence it passed directly into the world's commerce or entered the latter through Smyrna, Trieste, or some other Mediterranean entrepôt. At one time the more or less colored varieties were known as *gum gedda*, while the white and fine drug was known as *gum turic*, names derived from Jiddah and Tor, Red Sea ports, through which the varieties were supposed to be respectively exported. More recently three chief commercial varieties of Turkish or Egyptian gums were recognized. *Hashabi* or *Kordofan gum*, the finest of these varieties, was collected in the country westward of the White Nile; formerly it constituted the bulk of the superior gum arabic of commerce.

² In the lower forms of life the inner cell contents or protoplasm is often set free by the rapid conversion of the cellulose wall into a substance soluble in water, and in the higher plants, cells can be seen with one-half of their walls still cellulose, the other gum. According to Wigand, arabin is the result of a further change in bassorin, but F. von Hönel (*Ber. d. Chem. Ges.*, 1888) believes that while tragacanth is formed out of the cell wall, arabin is formed from the cell contents. According to the independent researches of Beljering and of Wiesner (*P. J.*, xvi. 284), the change of the cell wall is provoked by a peculiar ferment (*P. J.*, 1886, 840), which seems to be of bacterial origin. Various species of bacteria have been isolated from the diseased portion of gum producing plants by R. Greg Smith, who was enabled with them to produce a gum from saccharose, potato juice, and other vegetable substances. For details see *P. J.*, lxxii. p. 469. For general information concerning gum formation consult Hofmeister, *Handbuch der physiolog. Botanik*, Bd. iv. p. 368, 1865; Müller, *Sitzb. Akad. Wiss. Wien*, li. Juni, 1875; Mercadante, *Gaz. Chim.*; *Ber. d. Chem. Ges.*, 1876, p. 581; Graud, *A. J. P.*, 1878, p. 27; Prillieux, *C. R. A. S.*, t. lxxvii. p. 135; *Toxicologie Africaine*, vol. ii, p. 288.

¹ For further information in regard to gum bearing trees of Northern Africa, see *P. J.*, Aug. 1873; *C. R. A. S.*, t. lxxix. p. 1175; *Toxicologie Africaine*, Vol. ii.

Sennari or *Gehzirah* gum was an inferior variety, yielding a mucilage which turned sour more quickly than that produced by Kordofan gum. It was collected in a country eastward of the White Nile, and in the region of the Blue Nile. Still farther to the eastward was collected the Suakin or Talca gum.

Formerly, *Egyptian* gum was collected in all parts of the Soudan and Upper Egypt, and forwarded on the backs of camels to Assouan, at the head of the Nile navigation, often being many months en route. The closure of the Soudan by the Mahdi caused Egyptian gum almost to disappear from commerce, but the reopening of the region by the British government has resulted in large quantities of the gum being brought by rail to Assouan, whence after being sorted into three varieties it is put in palm-leaf sacks and sent down the Nile. The finest Egyptian gum consists of large roundish or smaller more or less irregular fragments, transparent but usually rendered opaque upon the surface by innumerable minute fissures. The inferior gum varies from yellow to dark-reddish as the quality deteriorates, and often contains impurities.¹ *Gedda* gum, sometimes spoken of as an Egyptian gum, enters commerce through Geddah, or Jiddah, on the Arabian side of the Red Sea. It seems to be the same as *Mecca* or *El Wisch* or *Aden* gums, which are sometimes spoken of as Egyptian gums, but are probably produced in the triangular peninsula which forms the eastern extremity of Africa.

Suakin gum, *Talca* or *Talha* gum, from *A. stenocarpa* and *A. Seyal*, is exceedingly brittle, and usually semi-pulverulent. It is a mixture of nearly colorless and brownish gums, is exported at Alexandria, and is sometimes termed *gum savakin*.

BARBARY GUM. (*Mogador* gum, *Morocco* gum.)—Mogador, a port of Morocco, is the chief entrepôt of the trade. The gum is probably derived, in part at least, from *A. nilotica*. According to Jackson, the natives call the tree which affords it *attaleh*. They gather it in July and August, when the weather is hot and very dry. Two kinds are brought to Mogador, one from the neighboring provinces, the other by caravans from Timbuctoo. This may account for the fact that Barbary gum in part resembles the Turkey, in part the Senegal. When first deposited in the warehouses, it has a faint odor, and makes a crackling noise, occasioned by rupture of small masses as they become more dry. Barbary gum is usually in tears, somewhat brownish, roundish or vermiform,

wholly soluble in water. It reaches the United States in casks through English commerce.

SENEGAL GUM.—This variety was introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade. St. Louis, at the mouth of the Senegal, and Portendie, considerably farther north, are the ports in which the commerce in gum chiefly centres. Immense forests exist in the interior, containing many species of the genus *Acacia*, all of which are said to yield gum, as is affirmed do also various trees belonging to other genera. The chief harvest begins in October and ends in December, although gum is also collected in March. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out and hardens in masses, which are often as large as a pigeon's egg, and sometimes as that of an ostrich. It is affirmed that the exudation is also largely caused by a parasitic plant, *Loranthus senegalensis*, the gummy exudation freely oozing out at the point where the parasite penetrates the bark. (*Ph. Centralh.*, Aug. 1895.) Senegal gum is usually in roundish or oval unbroken pieces, or in straight or curled cylindrical pieces of various sizes, in the finest grades whitish or colorless, but generally yellowish, reddish, or brownish red. The pieces are larger than those of Turkey gum, less brittle and pulverizable, and breaking with a more conchoidal fracture.² According to L. Liebermann, "gum Senegal" can be distinguished from Turkey gum arabic by heating the solutions for some time with potassium hydroxide. The "gum Senegal" does not alter in color, or becomes only very faintly yellow, while the Turkey gum arabic solution changes to an amber-yellow color (as do solutions of dextrin). (*A. J. P.*, 1891.)

INDIA GUM.³—*India* gum is not produced in India but reaches Bombay from Aden and the Red Sea ports, and is almost certainly the product of the Soudan, being therefore identical with Egyptian gum. It occurs in India in two

¹ A. Corre divides "gum Senegal" into the hard gums, which are of firm consistence, with a large, clear, shining fracture, and the soft or friable gums. *Galam* gum (*Gommes haut-du-fleuve*) is that coming from Galam, Podor, Bakel, and Medina; it is sometimes hard, sometimes soft; see 14th ed. U. S. D. *Gommes bas-du-fleuve* are from the deserts of Bounou and the country of the Braknas.

Brittle gum, *Salabreda*, or *Sadra-beida*, is supposed to be obtained from *A. albida* of the Flora of Senegambia, which is much smaller than *A. Vereke*, and characterized by its white bark. The gum is usually in small, irregular pieces, like coarse salt, probably the fragments of larger lumps, but sometimes in vermicular pieces about as thick as a goose-quill and of variable length. It is dull and often wrinkled externally, of a vitreous fracture, and of different tints of color, white, green, yellow, or orange. It is always somewhat bitter. Very easily soluble in its weight of water, it affords a mucilage of little consistence, which has but a slight effect on the tincture of litmus. When the solution is evaporated to the consistence of a paste, it absorbs moisture so as to become viscid; this property detracts much from its value. It is much less esteemed than is the Galam gum.

² *Persian* gum, which is said to be sent from Persia to Assouan to be packed as genuine gum arabic, can be distinguished from the latter, which it closely resembles, by its not dissolving in water. Sickenberger thinks that it is the product of *Prunus bokharensis* or of *P. puddum*.

³ H. C. Wood found that the gum arabic comes into Assouan in sacks or mats which are simply piled in rectangular roofless spaces surrounded by walls about ten feet high, made of dry mud. He was informed by the traders that the gum is gathered during the months of January, February and March by collectors having vested rights in a certain portion of the forests. Long incisions are made vertically through the bark and the exuding gum allowed to harden, the trees not being injured by the process, the collections going on from year to year.

forms, "Maklai," in large round tears or vermicular pieces, white, yellow or reddish, and much fissured; and "Maswai," in fragments and vermicular pieces similar in color and fissuring to the other variety. It is often crudely adulterated before reaching Europe, especially with *Bassora gum*, distinguished by its insolubility in water. Of recent years various India gums have come into commerce in increasing quantities as substitutes for true gum arabic. India gum is brought to this country partly from Calcutta or Bombay, and partly by way of England. It usually comes in large cases. We have seen a parcel said to have come directly from the Red Sea, enclosed in large sacks made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size.¹

¹ SUBSTITUTES FOR GUM ARABIC.—According to A. Mander, the East India gums appearing in the London market are:

Glossy Amrad Gum.—A dark gum consisting of more or less rounded and some stalactitic pieces, with smooth shining surface and free from internal cracks. Color varying from dark brown to pale yellow. Viscosity of mucilage (acacia being 1), 2.

East India Amrad Gum.—A dark brittle gum of a reddish tint, composed chiefly of transparent angular fragments with a few rounded masses having a conchoidal fracture. Viscosity of mucilage, 0.15.

Pale Amrad Gum.—This somewhat resembles "gum acacia sorts," being in broken angular pieces or small tears, and these more or less cracked internally; some pieces may be noticed having an opaline surface. Viscosity of mucilage, 0.156.

Amra or Omra Whatti Gum.—A dark gum, in irregularly-shaped and stalactiform pieces, clear internally, but surface dull; color from reddish to pale yellow. Viscosity of mucilage, 1.8.

Ghatti Gum.—A pale gum consisting of rounded or vermiciform pieces varying in size, clear internally, but dull and roughened on the surface, apparently caused by shrinkage in drying; from brownish-yellow to perfectly colorless and transparent. According to the *Pharmacographia Indica*, this gum is readily distinguished from all others by its dull white, roughened surface and glassy fracture free from cracks; it possesses about double the viscosity of gum arabic, and forms with water a nearly colorless mucilage which has a faint characteristic odor, and is gelatinized by basic acetate of lead and by borax, but not affected by ferric chloride or neutral lead acetate.

Of these gums (India gums of the London market) the first four varieties yield mucilages which are so dark-colored that they cannot be used in practical pharmacy. One part of ghatti gum rubbed up with three parts of distilled water and strained, yields a mucilage which is tasteless, odorless, colorless, and which is superior to the emulsion of gum arabic in its adhesive power, and even in its emulsive power, the emulsion made with it being almost of snowy whiteness. Ghatti gum would therefore seem to be thoroughly adapted for the purposes of pharmacy, and its extreme cheapness has led to its extensive use.

The studies of J. G. Prebble, of Bombay, throw much light upon the gums just spoken of. Through Oomrawuttee, or Amravti, the chief town of the Hyderabad assigned districts known as the Beras, two gums enter the world's commerce, which are respectively known in India as *Amrad* or *Babool* gum, and *Ghatti* gum. The *Babool* gum is apt to be dark, and is said to be a product of the *Acacia arabica*. It is without much doubt the *amra whatti* gum of Mander. *Amra* is the native name for a gum derived from *Spondias mangifera*, which gum, however, is said to resemble tragacanth rather than gum arabic. The Arabic word *hamra* means red, and possibly the term *amrad* is derived from it. The *amrad* gums of London appear to be made in Bombay by mixing *Babool* gum with other gums collected in various parts of India or imported into Bombay from the Red Sea coast.

EAST AFRICAN GUM.—Under the names of *Cape gum* and *East African gum*, a brittle, almost pulverulent gum enters commerce from

Ghatti gum is said to be obtained from *Anogeissus latifolia*, Wallich, in enormous quantities, to be much used in India, and to be exported from Bombay in the pure state.

Small quantities of gum are produced in India by a large number of trees often having no botanical relations with the acacias. For an account of these gums see *Pharmacographia Indica*, vol. 1.

Cape gums are imported into London in large quantities. Two varieties are recognized. The *glassy hard Cape gum*, the product of *Acacia horrida*, occurs in amber-brown-colored, irregular pieces, occasionally fissured, usually hard soluble in water, giving a dark-colored viscid mucilage free from odor but with an unusual flavor. This gum is said to be bleached and mixed with a pale gum. The *soft Cape gum* is believed to be derived from *Acacia giraffa*, Willd. Its inferior grades are dark brown and yield a bitter mucilage; the finest samples, however, so closely resemble in their physical properties and the mucilage which they yield, the Kordofan gums, that some authorities believe that they are true gum arabic which has been deflected southward by the closure of the Soudan, opened again.

Australian gum, or *Wattle gum*, is the product of *A. pycnantha*, Benth.; *A. decurrens*, Willd.; *A. homalophylla*, A. Gunn, and probably other species of *Acacia*. It is said that gums obtained near the coast and those procured in the interior do not contain metarabin. It occurs in hard pieces, elongated or globular; rough, varying in color from dark amber to pale yellow; entirely soluble in water, and yielding a very adhesive mucilage, which, when dry, is said not to crack. It sometimes contains tannin, and appears not to be suitable for pharmaceutical purposes. The wood of *A. homalophylla* is known as *violet wood*, on account of its pleasant odor. (*Am. Drug.*, 1884.)

Under the names of *Brazilian gum*, *Para gum*, and *gum angico*, large quantities of a gum occurring in large dark-amber or dark-brown glossy drops, soluble in water, are yearly thrown into commerce. It is said to be the product of *Acacia angico*. Its mucilage is very adhesive, but usually too dark in color for pharmaceutical purposes. It must be distinguished from the gum resin often known as *Brazilian gum*, which is said to be obtained from *Hymenaea courbaril*, and is used in making varnishes.

Chagal or *Magvey gum* of Chill occurs in hollow cylindrical pieces from 0.2 to 1.5 Cm. in thickness, occasionally having the form of stalactites or irregular tubers, but in nearly all cases showing the impression of the epidermis to which they have been attached. On their inner surface they are longitudinally streaked, while their outer surface is usually numerous fissured, the fissures penetrating deeply toward the interior. In the absence of these, the pieces are of glassy brightness, transparent, and of very dense structure internally. The color varies from colorless, through yellowish and brownish to a tolerably deep brown, isolated pieces being almost black. Maceration in water is said to reduce the dark pieces to a granular mass, while the transparent pieces dissolve almost entirely; the whole of the commercial sample yielding about five or six per cent. to cold water. The amount dissolved is greatly increased by the use of boiling water. According to the experiments made by Guehm, the commercial drug is scarcely fitted for technical use as a gum, but the clear pieces when made into a concentrated mucilage by prolonged heating answer the purposes of the calico printer well. *Puya chilensis*, *P. lanuginosa*, and *P. lanata* are commonly said to be the sources of the gum, though the researches of Hartwich make this uncertain. The exudation is asserted to be the result of the bite of a caterpillar, *Kastina elegans*. (*Zeit. Oest. Apoth. Ver.*, Aug. 1, 1896.)

Thos. Maben gives the following method of testing mucilage obtained from various gums sold for gum arabic as the best that he has been able to devise after much experimentation. Two or three drops of the mucilage prepared from the gum are placed on a glass or porcelain slab, and one or two drops of the following reagents added; these are then stirred together with a glass rod and the results compared. In the case of borax, acacia mucilage at once agglutinates or hardens into a gummy mass, similarly with basic lead acetate and ferric chloride, while it gelatinizes or forms a softer mass with potassium silicate. Similar reactions are given by the Senegal gums, the Indian *Amrad* gums, white Barbary, white and brown Cape, and Gedda

German East Africa. It is the product of various species of the genus *Acacia*. According to C. Mannich, gum yielded by *A. Vereck* and *A. Kirkii* contains no bassorin, while that which is derived from *A. Seyal*, *A. arabica*, and *A. stenocarpa* contains more or less of the bassorin. The gum from *A. usambarensis* occurs in brown masses of agglomerated tears, and contains so much bassorin that it forms a gelatinous mucilage.

General Properties.—Gum arabic is "in roundish tears of various sizes, or broken into angular fragments; whitish or yellowish-white, translucent; very brittle, with a glass-like, sometimes iridescent fracture; nearly inodorous; taste insipid, mucilaginous; insoluble in alcohol; slowly and completely soluble in water, forming an odorless, mucilaginous liquid, which shows an acid reaction with blue litmus paper, yields a gelatinous precipitate with basic lead acetate T.S., ferric chloride T.S., and concentrated solution of sodium borate. It is not colored blue (absence of starch) or red (absence of dextrin) by iodine T.S., nor does it yield a brownish-black precipitate with ferric chloride T.S., or reduce alkaline cupric tartrate V.S. The powder contains few, or no starch grains or fragments of vegetable tissues, and yields not more than 4 percent. of ash." *U. S.* "When dissolved in an equal weight of water, the solution should neither form a glairy mucilage nor, after admixture with more water, should it yield a gummy deposit on standing. The aqueous solution forms with solution of lead subacetate an opaque, and with solution of borax a more or less translucent, white jelly; it gives no precipitate with solution of lead acetate; is not colored blue or brown by a small quantity of solution of iodine (absence of starch or of ordinary 'dextrin' of commerce) nor bluish-black by test-solution of ferric chloride (absence of tannic acid); and does not give a red precipitate when boiled with solution of potassio-cupric tartrate (absence of certain sugars). Gum *Acacia* should not yield more than 4 per cent. of ash." *Br.* The commercial gum arabic contains 17 per cent. of water and 3 per cent. of ash, consisting almost entirely of calcium, potassium and magnesium carbonates.

The gum dissolves at ordinary temperature slowly, in an equal weight of water, forming a thick glutinous liquid of distinctly acid reaction. It is insoluble in alcohol, ether, and

the oils. 100 parts of diluted alcohol containing 22 per cent. of alcohol by volume dissolve 57 parts of gum, diluted alcohol containing 40 per cent. alcohol takes up 10 parts, and 50 per cent. alcohol only 4 parts (Flückiger). On adding hydrochloric acid to the aqueous solution and precipitating with alcohol, a colorless amorphous substance is obtained. This is *arabic acid*. On hydrolysis, it yields *galactose*, *arabinose*, and a pentabiose named *arabinon*. The *arabin* (or *arabic acid*) may also be prepared by placing a solution of gum, acidulated with hydrochloric acid, on a dialyzer, when calcium chloride will diffuse out, leaving behind solution of *arabin*.

Arabic acid dried at 100° C. (212° F.) has the composition $2C_5H_{10}O_5 + H_2O$; the water separates when it unites with bases. It has a decided tendency to form acid salts. Concentrated nitric acid forms with it nitro-compounds; diluted nitric acid, on the other hand, gives rise to mucic and saccharic acids, together with oxalic and a little tartaric acid. Diluted sulphuric acid on prolonged boiling gives rise to *arabinose*, or *arabin sugar* (*pectinose*, or *pectin sugar*), $C_5H_{10}O_5$, which reduces alkaline copper solution and turns the plane of polarization 121° to the right. Kiliani (*Ber. d. Chem. Ges.*, 1887, 339) first established the formula as given above, and it is now recognized as belonging to the class of *pentoses*. They are not fermentable, and on prolonged boiling with diluted hydrochloric acid, lose the elements of water and yield *furfural*, $C_5H_4O_2$. Neutral lead acetate does not precipitate an aqueous solution of gum arabic, but the basic acetate forms, even in a very diluted solution, a precipitate.

Prolonged heating of the dry gum causes it to change readily into *metarabic* (*metagummic*) acid, which is identical with the *cerasin* found in the beet and in cherry gum. Sulphuric acid will also change arabic into metarabic acid. 25 Gm. pure gum arabic are covered with 50 Cc. strong alcohol, 10 Cc. water, and 5 Cc. sulphuric acid, and allowed to stand 24 hours. On pouring off the fluid, and washing the residue with alcohol and with water, metarabic acid remains behind as a voluminous mass, which dries to a white, tasteless, and odorless powder of acid reaction. (Graeger, *Jahresbericht der Chem.*, 1872, 781.) The *metaplectic acid* which is prepared by Scheibler from the sugar beet is identical with metarabic acid.

The principle separated by cold water from the soluble *arabin* proves to be the same as metarabic (*metagummic*) acid prepared direct from the pure gum arabic by heating, or by the action of sulphuric acid. It is also identical with gum extracted from the sugar beet by Scheibler. In the normal and sound beet this gum is insoluble in water, and merely swells up like metarabic acid, while in altered beets there is found a portion (*arabin*) soluble in water. (Scheibler, *Ber. d. Chem. Ges.*, 1873, p. 612.)

gums. Barbary brown and Amrad give a jelly only with borax, otherwise they react as *acacia*. Australian gum agglutinates with borax, but only gelatinizes with basic lead acetate, and has no reaction with ferric chloride and potassium silicate. Brazilian gum has no reaction with potassium silicate, but gelatinizes with borax and ferric chloride and slightly with basic lead acetate. Ghatti gum gelatinizes with all four reagents, but in a slight degree only with potassium silicate. Oomra gum reacts similarly to *acacia*, except that it is entirely unaffected by basic lead acetate, and forms a softer jelly with ferric chloride. There are, of course, shades of difference in the various reactions which cannot be indicated by these terms, but, generally speaking, a fair idea is given of the nature of the gum. (*P. J.*, March 1, 1890, 717 to 721.)

The similarity of the reactions and composition of *arabinose* and *galactose* (from sugar of milk by inversion) led Kiliani to assert the identity of these two varieties of sugar, but later studies by himself, Claesson, and Scheibler have shown that they are distinct. Thus, *galactose* is fermentable, while *arabinose* is not; *galactose* yields mucic acid when oxidized with nitric acid, and dulseite when reduced with sodium amalgam, while *arabinose* does not yield either; the fusing point of the crystallized *galactose* is given at 142° to 144° C., while that of *arabinose* is 160° C.; *galactose* yields with phenylhydrazin a light yellow compound, fusing at 170° to 171° C., while *arabinose* forms a brownish-yellow compound, fusing at 157° to 158° C. (Scheibler, *Ber. d. Chem. Ges.*, 17, 1731.) *Arabinose* is said to be obtainable only from those varieties of gum arabic that yield no mucic acid when treated with nitric acid. (Claesson, *Ber. d. Chem. Ges.*, 14, 1271.)

Gum arabic undergoes no change by age, when kept in a dry place. Its concentrated aqueous solution remains for a considerable time unaltered, but ultimately becomes sour, from the production of acetic acid. The disposition to sour is increased by employing hot water in making the solution. The tendency of a weak solution to become mouldy is said to be obviated by adding a few drops of sulphuric acid, and decanting from the calcium sulphate deposited. (*A. J. P.*, 1872, 353.) Solution of gum arabic does not ferment upon the addition of yeast, saliva, or gastric juice; the addition of chalk and cheese, however, starts a fermentation which gives rise to lactic acid and alcohol, but not to mannite or glycerin. The addition of a solution of gum to an acidified albumin solution causes a precipitate, which disappears on further addition of gum, but the solution will then curdle and become flocculent on application of heat. Gum may be distinguished from dextrin by the following tests: 1. Gum contains no dextroglucose, which, however, is present in dextrin, and may be recognized by the copper test. (See *Alkaline Cupric Tartrate Volumetric Solution*, PART III.)¹ 2. Gum contains a lime compound; hence its

solution is rendered milky by oxalic acid, while a solution of dextrin remains almost clear. 3. Gum gives a slimy, yellow deposit when its solution is mixed with a neutral ferric salt.

The properties above enumerated belong to gum arabic generally. There are, however, varieties with differences which deserve notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidness of its solution. Under this head may be included the *gomme blanche fendillée* of Guibourt. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light, but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the unbroken pieces are somewhat opaque, each minute fragment is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medicinal use, and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guibourt has proposed for portions of this gum the name of *gomme pelliculée*, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mammillary appearance on the surface. It is less transparent than the former variety, is less freely and completely dissolved by water, and forms a more viscid solution. It dissolves with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities have been ascribed to variable proportions of *bassorin* or *cerasin* associated with the soluble *arabin*. Between these two varieties there are insensible gradations, so that it is not always very easy to classify specimens.

E. Bourquelot (*J. P. C.*, 1904 [6], 19, 473, 474) states that acacia contains an active oxidizing ferment which renders it unsuitable for use in many pharmaceutical preparations, and that, notwithstanding the wide use of acacia as an excipient, it is possible that certain active ingredients may become altered in its presence. Nor is acacia the only gum which contains a ferment; myrrh, frankincense and bdellium also contain an oxydase. Among the substances stated as being incompatible with acacia are pyrogallol, morphine, vanillin, ordinary phenol, cresylol, ortho- and meta-xylyl, thymol, carvol, *a*- and *b*-naphthol, pyrocatechol, guaiacol, phenols, lysol, cresols, acetylguaiacol, veratrol, creosol, eugenol, acetyleneugenol, methylaniline, ethylaniline, paratoluidine, crude aniline, xylydine,

¹J. Henry Schroeder examined twelve specimens of powdered acacia, and states that dextrin is not frequently used as an adulterant, and that if in using the alkaline cupric tartrate test the heat be prolonged during twenty minutes, a well-defined reduction was produced even when pure Senegal gum was used. This fact should be remembered in testing gums by the official method. (*A. J. P.*, 1897, 195.) R. G. Shoults (*A. J. P.*, 1900, 267) supplemented the conclusions of Schroeder and proposed to use the difference in rotatory power of acacia and dextrin as a test. He found a solution of pure acacia to have a laevorotatory power of -18°, while one of dextrin was dextrorotatory varying to the extent of from +120° to +138°. See also Kebler's paper (*Am. Drug.*, 1901, 343). The following test is given in the *Ph. Post*, 1894, 563. Add 3 Cc. of a solution consisting of 15 drops of solution of ferric chloride, 15 drops of a saturated solution of potassium ferrocyanide, 5 drops of HCl (1-125), and 60 Cc. of water to a 20 per cent. solution of the gum. If the gum arabic is pure, it will remain a clear yellow for from eight to ten hours. If there is dextrin present, the color changes to a blue.

a-naphthylamine, pyramidon apomorphine, eserine, adrenaline, isobarbaloin, caffeotannic acid, gallic acid and tannin. Paraxyleneol, hydroquinone, resorcinol, anisol and phenetol do not appear to be affected. Nor is the action confined to chemical substances; acacia is incompatible with the opium and Calabar bean products, suprarenal extract, aloetic preparations, and all substances flavored with vanillin; tannin-containing extracts such as those of rhatany, catechu, and rhubarb; fluidextract of viburnum prunifolium, and kola preparations. Obviously, in cases where mucilage of acacia is concerned, this oxidizing action may be eliminated by heating the liquid to 100° C., and thus destroying the ferment.

Specimens of gum arabic are sometimes found in commerce which are soluble in water with difficulty. According to Köchlin, if ten parts of such gum, fifty parts of water, and three parts of a 12 per cent. solution of hydrogen peroxide be heated together for two or three hours, the gum is rendered easily soluble. (*Nat. Drug.*, 1894, 176.) Related to the acacia gums

substance sometimes adheres to its surface, giving it a bitter taste, from which it may be freed by washing in water. Various adulterations of gum arabic have been practised, and substitutes offered for sale either honestly or with false labels. The high price of the genuine gum of late years has greatly stimulated the exploiting of these products. Starch, especially rice starch, which is difficult of detection on account of the small size of its granules, dextrin and inferior gums, are often added to powdered gum arabic. These foreign substances can usually be detected by the microscope or by appropriate tests for starch or dextrin even in powdered gum. (See page 6.) It has been proposed to change the arabinic acid of the sugar beet, by the method of Scheibler, into metarabinic acid, as the foundation of a true artificial gum arabic, but the artificial gums of the market have no such close chemical relation with the natural gum; many of them are mixtures of various substances, others are produced from starch by the action of sulphuric acid or by other means.

are wood gum, from the wood of foliage trees, yielding xylose on hydrolysis; *cherry gum*, the gum of cherry and almond trees, yielding *b*-arabinose on hydrolysis; *peach gum*, from the peach tree, yielding arabinose and galactose on hydrolysis; *barley gum*, obtained in the nitrogen-free extractive material of cereals, yielding galactose and xylose. Martina examined twenty-seven varieties of gum, and the composition of some of the principal ones is given in the above table.

Impurities and Adulterations.—In parcels of gum arabic there are sometimes pieces of a dark color, opaque, and incorporated with ligneous, earthy, or other impurities. The inferior are often mixed with, or substituted for, the better kinds, especially in powder; and portions of insoluble gum, bdellium, and other concrete juices of unknown origin, are found among the genuine. Flour or starch is sometimes fraudulently added to the powder, but is easily detected by the blue color which it produces with tincture of iodine. In consequence of the impurities and difference in quality, gum arabic should generally be garbled. A foreign

Universal Gum, a patented product obtained from potato starch, has been highly commended for the permanency and adhesiveness of its mucilage, but is said not to act well as an emulsifier. A substitute has also been made from Irish moss. (See *Chondrus*.) Gelatin is sometimes added to acacia as an adulterant; formaldehyde has been recommended by Trillet (*Ph. Post*, 1899, 629) as an agent for its detection. (See also *Proc. A. Ph. A.*, 1900, 643.)

Uses.—Acacia is used in medicine chiefly as a demulcent. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed to dissolve slowly. It has been used as a food, but has very little if any nutritive value. In pharmacy, gum arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered gum arabic are used, one a coarse powder called *granulated*, the other *finely dusted*. The granulated dissolves more readily in water, according to Hager, because it has lost during desiccation only two per cent. of moisture, while in pre-

paring the "finely dusted" powder the high heat necessarily used to thoroughly dry it, drives off ten per cent. of water. Its easy solubility and absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc.

ACETANILIDUM. U. S., Br.

ACETANILIDE

(ăc-ĕ-tăn-ĭ-lĭ'dŭm)

$C_6H_5NO = 134.09$

"The monacetyl derivative [$C_6H_5NH(CH_3.CO)$] of aniline." U. S. "Acetanilide, $CH_3.CO.NH.C_6H_5$, may be obtained by the interaction of glacial acetic acid and aniline." Br.

Acetylamidobenzene, Phenylacetamide; Acetanilid, Antifebrin; Acetanilide, Fr. *Cod.*; Acetanilidum, P. G.; Acetanilide, Antifebrina, It.; Acetanilida, Sp.

Acetanilide was introduced into the Pharmacopœia of 1890, and its very extensive use caused it to be retained in the U. S. P. (8th Revision). The process for its manufacture is not patented.

Preparation.—Acetanilide is made, according to Yvon, as follows: 372 grammes of pure aniline and 240 grammes of glacial acetic acid are heated for four hours, to the boiling point, in a flask provided with a reversed condenser; the excess of both ingredients is then distilled off on a sand bath, this being completed when the temperature reaches $260^\circ C.$ ($500^\circ F.$). The cooled, congealed residue is crude acetanilide, which may be purified by sublimation, or better, by repeated crystallization from water. The yield is about 400 Gm. It may also be prepared by acting on aniline with acetyl chloride (Gerhardt), or by heating aniline with acetamide (Kolbe). The sublimed salt is whiter and lighter than that obtained by crystallization from water, which has the appearance of boric acid. For Walters' method of preparing acetanilide, on a small scale, see *Bull. Pharm.*, 1899, 53.

Properties.—Acetanilide is described by the U. S. Pharmacopœia as in "colorless, shining, micaceous, crystalline laminae, or a crystalline powder; odorless, having a slightly burning taste, and permanent in the air. Soluble in 179 parts of water and in 2.5 parts of alcohol at $25^\circ C.$ ($77^\circ F.$); in 18 parts of boiling water, and in 0.4 part of boiling alcohol; also soluble in 12 parts of ether and 5 parts of chloroform at $25^\circ C.$ ($77^\circ F.$). When heated to $113^\circ C.$ ($235.4^\circ F.$) Acetanilide melts, and at $295^\circ C.$ ($563^\circ F.$) it boils without decomposition. Upon ignition it is consumed without leaving a weighable residue. Solutions of Acetanilide in simple solvents are neutral to test-paper. If 0.5 Gm. of Acetanilide be agitated with 5 Cc. of colorless sulphuric acid in a clean test-tube, it dissolves without imparting color to the liquid. On heating 0.1 Gm.

of Acetanilide with 5 Cc. of concentrated solution of potassium hydroxide (1 in 4), the characteristic odor of aniline becomes noticeable. On now adding 1 Cc. of chloroform, and again heating, the disagreeable odor of phenyl isocyanide (a poisonous product) is evolved (distinction from methylacetanilide or antipyrine). On boiling 0.1 Gm. of Acetanilide for several minutes with 2 Cc. of hydrochloric acid, a clear solution results, which, when mixed with 3 Cc. of an aqueous solution of phenol (1 in 20), and afterwards with 5 Cc. of a filtered, saturated solution of chlorinated lime, acquires a brownish-red color, becoming deep blue upon supersaturation with ammonia water. On heating 0.1 Gm. of Acetanilide with 10 Cc. of water, filtering the solution when cold, and adding bromine T.S., drop by drop, to the filtrate, a whitish precipitate of parabromacetanilide is formed (distinction from antipyrine or acetphenetidim). A cold saturated, aqueous solution of Acetanilide added to ferric chloride T.S. should not affect the color of the latter (absence of aniline salts and various allied substances)." U. S. "Melting point, when dry, $236.5^\circ F.$ ($113.5^\circ C.$). It is soluble in 200 parts of cold or 18 parts of boiling water, and in 4 parts of alcohol (90 per cent.), freely soluble in ether, benzol, and chloroform. On boiling with test-solution of ferric chloride a reddish-brown color is produced, and this is almost entirely discharged by hydrochloric acid. If Acetanilide be heated with solution of potassium hydroxide until the odor of aniline is given off, and the liquid be then warmed with a few drops of chloroform, the unpleasant and penetrating odor of phenyl-isocyanide (isocyanide) is developed; and an aqueous solution mixed with solution of bromine gives a yellowish-white precipitate (distinctions from phenacetin). Heated with free access of air it burns, leaving no residue. With sulphuric acid or with cold nitric acid it forms a colorless solution. A cold saturated aqueous solution does not affect solution of litmus (absence of free acid), and is not affected by test-solution of ferric chloride (absence of acetone, phenazone, and salts of aniline)." Br.

Ritsert (*Ph. Ztg.*, 1890, 306) believes that the difference in melting point of acetanilide given by various writers is due to the almost constant presence of toluidine in aniline, and the production of acetoluids which have the following melting points: *ortho*, $107^\circ C.$; *meta*, $65.5^\circ C.$; and *para*, $147^\circ C.$ A very important reaction, by which the presence of acetoluid may be detected in acetanilide, is in the use of a boiling solution of potassium permanganate. If the acetanilide be pure, it is not altered, and does not reduce the permanganate, but acetoluid, if it be present, is oxidized to acetamidobenzoic acid with reduction of the permanganate. Of a number of samples of acetanilide examined, in only one was the reduction slight, while all the others showed a decided reduction.

Uses.—The effects of acetanilide upon man are very similar to those produced by antipyrine,—namely, after small doses, quietness; after very large doses, malaise, a little headache, singing in the ears, weakness, and a peculiar cyanosis, with some tendency to somnolence, mydriasis, and, if there has been fever, marked fall of temperature usually accompanied by, but not dependent upon, a profuse sweat. After enormous doses complete coma and collapse have been noted. It has in rare instances caused collapse and cardiac failure, and a peculiar measles-like eruption is not very uncommon. Large toxic doses have caused in animals and in man anæsthesia, loss of reflex activity, tremors, irregular failing respiration, convulsions, coma, and general paralysis. The cyanosis is due to the formation of methæmoglobin in the blood. In the animal system acetanilide appears to break up into acetic acid and aniline, the aniline in turn undergoing oxidation into *paramidophenol*, which unites with sulphuric acid to be eliminated as paramidophenol sulphate.

Death has, in a number of cases, been produced by acetanilide when used for medicinal purposes. Five grains (0.32 Gm.) are alleged to have caused fatal heart failure (*Ind. Med. Jour.*, Sept. 1890); but there have been instances of recovery after the dose of an ounce (31 Gm.). Sixty grains (3.9 Gm.) have frequently been followed by serious collapse and in some cases by death. It is also necessary to exercise some care in the external use of the drug, for various cases of severe poisoning have been reported as caused by such use.

There is a wide spread but perhaps not well-grounded belief in the profession that accidents are more rare after acetanilide than after antipyrine, but the medicinal application of acetanilide seems to be identical with that of antipyrine, save only as it is modified by the insolubility of acetanilide. It is also somewhat more powerful than antipyrine, its full dose being ten grains (0.65 Gm.), repeated if necessary; preferably administered in capsules or wafers. For details of medicinal use, see *Antipyrina*. Acetanilide is germicidal, and seems to be especially active in inhibiting the growth of pathogenetic organisms. It is also analgesic, and affords a very useful dressing for wounds and ulcers. The drug itself may be used in the form of a fine powder, or an ointment may be employed in the strength of from 10 to 50 per cent. In certain mucous inflammations, as *vaginitis* and *wrethritis*, a local application (20 to 40 grains to the fluidounce) has been found very effective. Acetanilide may be given in the form of powder, suspended in mucilage of acacia and syrup, or in the form of tablets or capsules.

Dose, from five to eight grains (0.32 to 0.5 Gm.).

Off. Prep.—*Pulvis Acetanilidi Compositus*, U. S.

ACETONUM. U. S.

ACETONE

(ăç-ê-tŏ'nŭm)

"A liquid containing not less than 99 per cent., by weight, of absolute Acetone [Dimethylketone, $\text{CH}_3\text{CO}\cdot\text{CH}_3 = 57.61$]. It should be kept in well-closed vessels in a cool place, remote from lights or fire." U. S.

Pyroacetic Spirit, Dimethyl Ketone; Acétone, Ether (Esprit) pyroacétique, *Fr.*; Aceton, Essigäther, Mesitalkohol, *G.*; Acetone, Chetone, Metilacetone, *It.*

Preparation.—Acetone is found in small amount in normal urine, in blood, etc., and in larger amount in certain pathological conditions. Acetone is produced by the dry distillation of sugar, gum, cellulose, etc., and therefore is always contained in crude wood naphtha.

E. R. Squibb has also prepared it on a large scale by passing acetic acid vapor through a rotating iron cylinder heated to from 500° to 600° C. and containing pumice stone with precipitated barium carbonate. (*J. Am. C. S.*, 1895, 197.) Prepared commercially by the dry distillation of calcium acetate, it boils at 56° C., and has a peculiar ethereal odor and sharp, burning taste.

Properties.—The official description is as follows: "A transparent, colorless, mobile and volatile liquid of a characteristic ethereal odor and a pungent, sweetish taste. Specific gravity: 0.790 at 25° C. (77° F.). Miscible with water in all proportions, without cloudiness, also miscible with alcohol, ether, chloroform, and volatile oils. It volatilizes at low temperatures and boils at 56.5° C. (133.7° F.). It is inflammable and burns with a luminous non-sooty flame. It should not affect the color of blue or red litmus paper previously moistened with water. If 50 Cc. of Acetone be evaporated in a clean glass vessel no weighable residue should remain. If 20 Cc. of Acetone contained in a clean glass-stoppered vial be mixed with 0.1 Cc. of tenth-normal potassium permanganate V.S., the pink tint produced by the admixture should not wholly disappear in less than 15 minutes (limit of *empyreumatic substances*)." U. S.

Distilled with water and chlorinated lime, it yields nearly 200 per cent. of its weight in chloroform, and is hence largely used in the manufacture of this substance, both in this country and in Germany. In the presence of an alkali, iodine converts it into iodoform, so that a trace of acetone in methyl alcohol can be detected by iodoform formation (Kraemer's test).

Schlagdenhauffen asserts that commercial acetone contains an alkaloidal substance. (*P. J.*, 1884, 163.) For a method of detecting acetone in urine, see *A. J. P.*, 1889, 175. See also *Proc. A. Ph. A.*, 1894, 281; 1897, 690; *Ephem.*, 1895, 1653; *Chem. News*, 1899, 252, 262.

Acetone oil, largely a mixture of higher ketones, obtained as a by-product in the manufac-

ture of acetone and suggested by Lang as an addition to alcohol and spirits to denaturize them, cannot be used on a large scale as pointed out by Klar, as the commercial supply would probably be insufficient. (*Chem. News*, 1899, 205.)

Uses.—Acetone is rarely used in medicine, but has been introduced into the U. S. Pharmacopœia (8th Rev.) mainly as a menstruum in making oleoresins (see *Oleoresina*). It is used largely as a solvent for fats, resins, and camphors.

ACETPHENETIDINUM. U. S. (Br.)

ACETPHENETIDIN

(ăc-ět-phen-ět-i-dī-nŭm)

$C_{10}H_{13}NO_2 = 177.79$

"A phenol derivative [Acetparaphenetidin, $C_6H_4(OC_2H_5).NH.CH_3.CO$ 1:4], the product of the acetylation of para-amidophenol." U. S. "Para-acet-phenetidin, $C_2H_5O.C_6H_4.NH.COCH_3$, or Phenacetin, is produced by the interaction of glacial acetic acid and para-phenetidin, a body obtained from para-nitrophenol." Br.

Phenacetinum, Br., P. G.; Para-acetphenetidin, Para-ethoxyacetanilide; Phenacetin; Acet-Phénétidine, *Fr. Cod.*; Phénacétine, Para-acétophénétidine, *Amide* Actique de l'amido-phénétol, *Fr.*; Fenacetina, *It., Sp.*

The chemical relationship of this body to phenol is seen by an examination of its formula and the formulas of the intermediate compounds obtained as stages in its preparation.

Phenol, $C_6H_5.OH$, is converted into *nitrophenol*, $C_6H_4(NO_2)OH$. Only the paranitrophenol is available, and this is separated by distilling off the ortho-nitrophenol by steam distillation. The residual *paranitrophenol*, in the form of the sodium compound, is treated with ethyl bromide, when ethyl paranitrophenol or *paranitrophenetol*, $C_6H_4(NO_2)OC_2H_5$, is produced. This is now reduced by the action of hydrochloric acid and iron turnings to *paraphenetidin*, $C_6H_4(NH_2)OC_2H_5$. Glacial acetic acid then serves to introduce the acetyl group, and *para-acetamidophenetol* (phenacetin), $C_6H_4(NHC_2H_5O)OC_2H_5$, is obtained.

Properties.—Acetphenetidin occurs in "white, glistening, crystalline scales or fine crystalline powder, odorless and tasteless. It is soluble in 925 parts of water, 12 parts of alcohol, 63 parts of ether, and 20 parts of chloroform, at 25° C. (77° F.); in 70 parts of boiling water and in 2 parts of boiling alcohol. Heated to between 134° and 135° C. (273.2° and 275° F.) it melts, and at a higher temperature burns without leaving a weighable residue. It dissolves without color in sulphuric acid, but if shaken with nitric acid it is colored yellow, which color persists when heated. If 0.1 Gm. of Acetphenetidin be boiled for one minute with 1 Cc. of concentrated hydrochloric acid and the solution diluted with 10 Cc. of water,

cooled and filtered, it should yield on the addition of 3 drops of an aqueous solution of chromium trioxide (1 in 30) a ruby red color. On heating 0.1 Gm. of Acetphenetidin with 5 Cc. of a concentrated solution of potassium hydroxide (1 in 4), the odor of aniline should not be perceptible. If 0.1 Gm. of Acetphenetidin be boiled with 10 Cc. of water it should yield a solution which, when cooled and filtered, should not become turbid upon the addition of bromine T.S. in slight excess (absence of *acetanilide*). If 0.1 Gm. of Acetphenetidin be boiled for one minute with 3 Cc. of solution of sodium hydroxide (1 in 2), the solution cooled, and then agitated with 5 Cc. of a solution of chlorinated soda, there should be produced a clear yellow liquid, and not a purplish-red or brownish-red cloudy liquid or precipitate (absence of *acetanilide*). A mixture of 0.3 Gm. of Acetphenetidin with 1 Cc. of 90 percent. alcohol should not acquire a red tint when diluted with three times its volume of water and boiled with one drop of tenth-normal iodine V.S. (absence of *paraphenetidin*)." U. S. The British Pharmacopœia gives the following tests for phenacetin. "0.1 gramme boiled with 2 cubic centimetres of *hydrochloric acid* for half a minute yields a liquid which, diluted with ten times its volume of *water*, cooled, and filtered, assumes a deep-red coloration on the addition of *solution of chromic acid*. Heated with free access of air it burns, leaving no residue. *Sulphuric acid* dissolves it without color. A cold saturated aqueous solution should not become turbid on the addition of *solution of bromine* (absence of *acetanilide*). A mixture of 0.3 gramme of Phenacetin with 1 cubic centimetre of *alcohol* (90 per cent.) should not acquire a red tint when diluted with three times its volume of *water*, and boiled with one drop of *volumetric solution of iodine* (absence of *paraphenetidin*)." Br. The test with chromic acid will serve to distinguish it from acetanilide and exalgin; that with bromine water will indicate the absence of phenol and acetanilide, both of which will show a white turbidity, owing to the formation of difficultly soluble bromine derivatives. The presence of unchanged paraphenetidin may be detected by melting 2.5 Gm. of hydrated chloral in a test tube and adding 0.5 Gm. of the acetphenetidin to be tested. If pure, it will remain colorless; if paraphenetidin be present, it will become violet or reddish blue in tint. For further information see a paper in *Proc. A. Ph. A.*, 1903, 180, on an examination of samples of commercial phenacetin by G. M. Beringer, and *Proc. A. Ph. A.*, 1903, 365, for a paper by L. F. Kebler on its history, methods of manufacture, and chemical constitution.

Uses.—Acetphenetidin was first introduced as an antipyretic by Hinsberg and Kast, who found that in order to produce toxic effects in the lower animals enormous doses are required. These cause vomiting, staggering, hurried respiration, somnolence, cyanosis, and methæmoglobinization of the blood. In man no fatal

cases of poisoning have been reported, but Hollopeter saw twenty-two and a half grains produce in a woman collapse, with cyanosis. Acetphenetidin would seem to be one of the safest, as it certainly is one of the most efficient, drugs of its class. It is asserted that its antipyretic action is more gradual, more prolonged, and less apt to be attended with disagreeable symptoms than that of antipyrine and other allied drugs. The experiments of Ott and of Cerna and Carter appear to prove that the fall of temperature produced by acetphenetidin is due to a lessened production of animal heat caused by a direct influence of the drug upon the thermogenetic centres, and is not necessarily accompanied by any distinct alteration of the circulation. H. C. Wood, Jr., (*Univ. Med. Mag.*, July, 1900) found that when it is given intravenously it has no effect on blood pressure, but that in enormous doses it paralyzes respiration. It seems also to be a depressant to the spinal cord. As an antipyretic and as an analgesic, acetphenetidin appears to cover in its usefulness the same range as does antipyrine. In nervous headache the combination of it with caffeine (twelve grains to three) is often singularly advantageous. By many, acetphenetidin is believed to be less depressing than is antipyrine. Urticaria has been noted after its use, but it seems not to produce any characteristic eruption. According to Reuter, *paraphenetidin*, which is liable to occur in commercial phenacetin, is a dangerous poison, especially acting upon the kidneys.

Dose, from five to fifteen grains (0.32 to 1 Gm.).

ACETUM CANTHARIDIS. Br.

VINEGAR OF CANTHARIDES

(a-cē'tūm cān-thār'ī-dīs)

Vinaigre cantharidé, *Fr.*; Canthariden-Essig, *G.*

"Cantharides, bruised, 2 ounces (Imperial) or 100 grammes; Glacial Acetic Acid and Distilled Water, mixed in equal volumes, a sufficient quantity. Macerate the Cantharides in eighteen fluid ounces (Imp. meas.) or nine hundred cubic centimetres of the mixture of Glacial Acetic Acid and Distilled Water for twenty-four hours; transfer to a percolator: when the liquid ceases to pass, pour sufficient of the menstruum in successive portions over the contents of the percolator to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Vinegar of Cantharides." *Br.*

This preparation was formerly official in all the Pharmacopœias of the British Islands; but it was omitted in the first British Pharmacopœia, to be resumed in the last two revisions. The mode of preparation differs mainly in the partial substitution of percolation for maceration and expression. Glacial acetic acid is now directed to be mixed with an equal volume of

distilled water as the menstruum. This is better than the former method of mixing two kinds of acetic acid of different strengths.

Procter found that, by digestion at a temperature of 100° C. (212° F.), the active principle of the flies is readily taken up by official acetic acid, though a portion of the cantharidin is deposited upon cooling. (*A. J. P.*, xxiv. 299.) It would seem, therefore, that the vinegar of Spanish flies would be best prepared with the aid of heat; and, to a certain extent, this advantage is enjoyed in the present process. Greenish and Wilson (*P. J.*, 1898, 259) propose to make this preparation directly from the active principle, by dissolving 1 Gm. of cantharidin in 200 Cc. of glacial acetic acid and adding sufficient diluted acetic acid to make 2000 Cc.¹

Uses.—This preparation is intended exclusively for external use, as a speedy epispastic. It is said, when lightly applied by a brush, to act as a rubefacient; and, when rubbed freely upon the skin for three minutes, to be followed in two or three hours by full vesication. The pain produced by the application, though more severe, is also more transient than that occasioned by the blistering cerate.

ACETUM IPECACUANHÆ. Br.

VINEGAR OF IPECACUANHA

(a-cē'tūm ip-e-cāc-ū-ūn'hæ)

Vinaigre d'Ipecacuanha, *Fr.*; Brechwurzel-Essig, *G.*

"Liquid Extract of Ipecacuanha, 1 fl. ounce (Imperial measure) or 50 cubic centimetres; Alcohol (90 per cent.), 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Diluted Acetic Acid, 17 fl. ounces (Imp. meas.) or 850 cubic centimetres. Mix; filter, and if necessary add sufficient Diluted Acetic Acid to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Vinegar of Ipecacuanha." *Br.*

The process for this vinegar was changed materially in the last revision of the British Pharmacopœia, liquid extract of ipecacuanha

¹ The *Vinegar of colchicum* (acetum colchici) was omitted in the U. S. Pharmacopœia 1870, although a very active preparation. The following is the article on it in the 14th edition of the U. S. Dispensatory. "Take of Colchicum Root, in fine powder, two troy ounces; Diluted Acetic Acid a sufficient quantity. Moisten the powder with a fluidounce of Diluted Acetic Acid, allow it to stand for half an hour, pack it firmly in a conical glass percolator, and gradually pour upon it Diluted Acetic Acid until the filtered liquid measures two pints. Vinegar of Colchicum may also be prepared by macerating the Colchicum Root, in moderately fine powder, with two pints of Diluted Acetic Acid, in a close glass vessel, for seven days; then expressing the liquid, and filtering through paper." *U. S.*

Vinegar is an excellent solvent of the active principle of colchicum, and the alkaloid of the latter loses none of its efficacy by combination with the acetic acid of the former. Of the two formulas above given, the first, directing percolation, is much preferable to the second, permitting maceration, if performed by competent hands; and the same remark will apply to all the medicated vinegars in which an alternative formula is given. This preparation is effective in doses of thirty drops to two fluidrachms (1.9 to 7.5 Cc.).

diluted with a mixture of alcohol and diluted acetic acid replacing the old method of percolating the drug with diluted acetic acid. It will be found, however, that after the vinegar has been made a few months the odor of acetic ether will be developed; this is sometimes objectionable. The words in the process "if necessary" might have been omitted, as slight loss in filtration always occurs. Diluted Acetic Acid is a good menstruum for ipecacuanha, and this vinegar will doubtless prove effective as an expectorant.

Dose, five to forty minims (0.3 to 2.5 Cc.).

ACETUM OPII. U. S.

VINEGAR OF OPIUM

(a-cē'tūm ō'pī-i)

Black Drop; Vinaigre d'Opium, *Fr.*; Opium-Essig, *G.*

* "Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Myristica, in No. 30 powder, *thirty grammes* [or 1 ounce av., 25.5 grains]; Sugar, *two hundred grammes* [or 7 ounces av., 24 grains]; Diluted Acetic Acid, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fl. oz., 6½ fluidrachms]. Macerate the Opium and Myristica in *five hundred cubic centimeters* [or 1 pint] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin of close texture, and express the liquid. Mix the residue with *two hundred cubic centimeters* [or 7 fluid-ounces] of Diluted Acetic Acid until a uniform magma is produced, then strain and express again. Mix and filter the strained liquids, dissolve the Sugar in the filtrate, and pass enough Diluted Acetic Acid through the filter to make the product measure *one thousand cubic centimeters* [or 33 fl. oz., 6½ fluidrachms]." *U. S.*

The U. S. P. 1890 directed this vinegar to be tested to show its alkaloidal value as follows: "To assay this preparation, transfer 100 Cc. of it to a small capsule, add 4 Gm. of precipitated calcium carbonate, or such a quantity as will be sufficient to neutralize the free acid, and then proceed further as directed under *Tinctura Opīi*. It should yield from 1.3 to 1.5 Gm. of crystallized morphine." *U. S.* 1890. The U. S. P. (8th Rev.) dropped the assay process, because the presence of sugar and the other ingredients rendered such a process unreliable. (See *A. J. P.*, 1894, 136.) The maintenance of a uniform standard strength is secured through the use of an assayed powdered opium in this preparation.

Many will doubtless prefer to make vinegar of opium entirely by maceration. This may be done by placing the powder in a suitable bottle and pouring on the diluted acetic acid, agitating frequently, after allowing the maceration to proceed seven days, expressing, and filtering. The vinegar of opium was introduced into the Pharmacopœias for use as an imitation of *Castor* or *Quaker black drop*, or simply *black*

The formula of the first edition of the U. S. P. was so deficient in precision, and so uncertain in its results, that it was abandoned in the second edition; but, as these objections were obviated in a process by Charles Ellis (*A. J. P.*, vol. ii. p. 202), it was deemed proper to restore it to its official rank at the subsequent revision of the Pharmacopœia. The advantages of the black drop over laudanum are, probably, that disturbing principles contained in opium and soluble in alcohol are left behind by the aqueous menstruum employed, while the morphine meconate is converted by the acetic acid into the acetate. In the original process, published by Armstrong, who found it among the papers of a relative of the proprietor in England, *verjuice*, or the juice of the wild crab, was employed instead of vinegar. Other vegetable acids also favorably modify the narcotic operation of opium; and lemon juice has been employed in a similar manner to vinegar. For the process official in the first ed. U. S. P., see 14th edition U. S. Dispensatory.

Vinegar of opium may sometimes be advantageously used when opium itself, or the tincture, occasions headache, nausea, or nervous disorder. Formerly this preparation was double the strength of laudanum; now it has the same strength. The smallness of the dose was one of its great advantages, but since the weakening, first authorized by the U. S. Pharmacopœia of 1880, this preparation has almost entirely gone out of use.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

ACETUM SCILLÆ. U. S., Br.

VINEGAR OF SQUILL

(a-cē'tūm scīl'læ)

Acetium scilliticum; Meerzwiebel-Essig, *G.*; Vinaigre de scille, *Fr. Cod.*; Vinaigre scillitique, *Fr.*; Aceto scillitico, *It.*; Vinagre de escila, *Sp.*

* "Squill, in No. 20 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Diluted Acetic Acid, *a sufficient quantity*, to make *one thousand cubic centimetres* [or 33 fl. oz., 6½ fluidrachms]. Macerate the Squill with *nine hundred cubic centimeters* [or 30 fluidounces] of Diluted Acetic Acid during seven days, frequently stirring; then strain through muslin, and wash the mass on the strainer with enough Diluted Acetic Acid to make the strained liquid measure nearly *one thousand cubic centimeters* [or 33 fl. oz., 6½ fluidrachms]. Heat this liquid to boiling, filter while hot, and when cooled add sufficient Diluted Acetic Acid to make the product measure *one thousand cubic centimeters* [or 33 fl. oz., 6½ fluidrachms]." *U. S.*

"Squill, bruised, 2½ ounces (Imperial) or 125 grammes; Diluted Acetic Acid, 1 pint (Imp. meas.) or 1000 cubic centimetres or a sufficient quantity. Exhaust the squill by the process of maceration as directed for Tinc-

tures. The resulting Vinegar of Squill should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

Vinegar of Squill may also be prepared by percolating the Squill with the Diluted Acetic Acid after previous maceration with an equal bulk of the Diluted Acetic Acid (this precaution being necessary in order to satisfy thoroughly its tendency to swell) and filtering through paper.

The process now official differs from that of the U. S. Pharm. of 1890 in directing the heating of the strained liquid to coagulate albuminous matter and filtering, so that when the vinegar is mixed with sugar and water, in making syrup of squill, a transparent syrup may be secured.

This was formerly official in the Lond., Ed. and Dub. Colleges, but was omitted as a distinct preparation in the first British Pharmacopœia, reintroduced in 1874 and since retained. As vinegar of squill is apt to be injured by keeping, it should be prepared in small quantities, as wanted for use. The British preparation is a trifle stronger than that of the U. S. P. (8th Rev.). As was shown by E. Gregory (*Can. Pharm. Journ.*, Oct., 1875), the spirit added to it in the former British formula was of no use as a preservative. In the German Pharmacopœia 5 parts of squill are macerated in a mixture of 9 parts of acetic acid (30 per cent.), 36 parts of water, and 5 parts of alcohol, for three days, with frequent shaking, strained without forcible expression, allowed to stand 24 hours, and then filtered. In the Codex, 12 parts of white vinegar are used to macerate 1 part of squill for eight days. Vinegar of squill is employed chiefly in preparing the syrup.

Uses.—This preparation has all the properties of the squill in substance, and is occasionally prescribed, but the syrup is usually and properly preferred. It should be given in cinnamon water, mint water, or other aromatic liquid.

Dose, from fifteen minims to a fluidrachm (0.9 to 3.75 Cc.), but the latter quantity would be apt to nauseate.

Off. Prep.—Syrupus Scillæ, *U. S.*, *Br.*

ACIDUM ACETICUM. *U. S.*, *Br.*

ACETIC ACID

(ăc'î-dŭm ă-cĕt'î-cŭm)

"A liquid composed of not less than 36 percent., by weight, of absolute Acetic Acid [$\text{CH}_3\text{COOH} = 59.58$], and about 64 percent. of water, and obtained by the oxidation of ethyl alcohol or by the destructive distillation of wood." *U. S.* "Acetic acid is a product of the destructive distillation of wood, and of the oxidation of ethylic alcohol. 100 parts by weight should contain 33 parts of hydrogen acetate, CH_3COOH , and 67 parts of water." *Br.*

Acetum Concentratum; Acide acétique, *Fr. Cod.*; Acidum Aceticum Dilutum, *P. G.*; Essigsäure, *G.*; Acido acetico, *It. Sp.*

Off. Prep.—Acidum Aceticum Dilutum, *U. S.*, *Br.*; Liquor Ammonii Acetatis, *Br.*; Oxy-mel, *Br.*; Oxy-mel Scillæ, *Br.* Acetic Acid is also used officially, as a menstruum, diluted to various strengths.

ACIDUM ACETICUM DILUTUM.

U. S., *Br.*

DILUTED ACETIC ACID

(ăc'î-dŭm ă-cĕt'î-cŭm dî-lŭ'tŭm)

"It should contain not less than 6 percent., by weight, of absolute Acetic Acid [$\text{CH}_3\text{COOH} = 59.58$], and about 94 percent. of water." *U. S.* "100 parts by weight should contain 4.27 parts of hydrogen acetate, CH_3COOH ." *Br.*

Acetum Destillatum; Acide acétique diluée, *Fr.*; Acetum, *P. G.*; Reiner Essig, Verdünnte Essigsäure, *G.*

ACIDUM ACETICUM GLACIALE.

U. S., *Br.*

GLACIAL ACETIC ACID

(ăc'î-dŭm ă-cĕt'î-cŭm glă-cî-ă'lă)

$\text{HC}_2\text{H}_3\text{O}_2 = 59.58$

"A liquid containing not less than 99 percent., by weight, of absolute Acetic Acid [$\text{CH}_3\text{COOH} = 59.58$], and not more than 1 percent. of water." *U. S.* "100 parts by weight should contain 99 parts of hydrogen acetate, CH_3COOH ." *Br.*

Acidum Aceticum Concentratum; Acidum Aceticum, *P. G.*; Acide acétique cristallisable, *Fr. Cod.*; Acide acétique concentré, Vinaigre glacial, Esprit de vinaigre, *Fr.*; Essigsäure, Eissig, *G.*; Acido acetico concentrato, *It.*

Three strengths of acetic acid are now official in the *U. S.* and *Br. Pharmacopœias*. These are *Acidum Aceticum Glaciale*, of sp. gr. 1.049 at 25° C. (77° F.), *U. S.* and 1.053 at 15.5° C. (60° F.), *Br.*; *Acidum Aceticum*, of sp. gr. 1.045, *U. S.*, and 1.044, *Br.*, and *Acidum Aceticum Dilutum*, sp. gr. 1.009, *U. S.*, and 1.006, *Br.*

We shall consider these grades separately, in the order of their strength.

Acidum Aceticum Glaciale.—A process for this preparation was given in the British Pharmacopœia of 1864, which consisted in first heating sodium acetate so as to drive off all its water of crystallization, then, after cooling, distilling it with concentrated sulphuric acid, and, finally, if the resulting acetic acid, upon being tested with a mixture of solution of potassium iodate and a little mucilage of starch, was found to contain sulphurous acid, agitating the distilled acid with perfectly dry black manganese oxide, and again distilling. The object of the process was to furnish an acid of the maximum strength. But, on trial, it was not found to be satisfactory, as the resulting acid was not truly glacial, and always contained sul-

¹ Add if the temperature is above, subtract if the temperature is below, 25° C.

² Corresponding with a difference in specific gravity of 0.0001.

NOTE.—If the specific gravity $\left(\frac{25^\circ \text{C.}}{25^\circ \text{C.}}\right)$ of the acid be greater than 1.045, mix with some of the acid an equal weight of water before taking the specific gravity, and multiply the percentage taken from the table by two. It is better, however, to determine the strength of any sample of Acetic Acid by its "normality."

To find the weight in grammes of absolute Acetic Acid in 100 Cc., multiply the specific gravity by the per cent. of absolute acid.

To find the volume per cent. of official Acetic Acid, multiply the "normality" by 15.87. For the volume per cent. of Glacial Acetic Acid, multiply the "normality" by 8.71. For the volume per cent. of official Diluted Acetic Acid, multiply the "normality" by 99.

phurous acid. (C. H. Wood, *P. J.*, 1867, 17.) The following modification of the process does, however, yield a pure product. After the crystallized salt has been fused in an iron dish in its own water of crystallization, and has dried out, it is again brought to fusion by increased heat, whereby, if the heat applied be not too strong, no acid is decomposed or vaporized. The anhydrous salt is then treated with half a molecule of sulphuric acid (for 82 parts anhydrous acetate 49 parts of strongest sulphuric acid), which according to Mohr and Buchner, suffices, instead of twice the amount, usually employed. No sulphurous acid is liberated in this case. A process to be followed on a large scale, practically the counterpart of this, is given in a foot-note, page 18, 14th ed. U. S. Dispensatory.

Acetic acid of maximum strength may also be obtained by distilling dried potassium acetate at a heat between 199° C. (390° F.) and 299° C. (570° F.). One molecule of monohydrated acetic acid distils over, and neutral potassium acetate is left. The acid acetate may be formed by evaporating a mixture of the neutral acetate with an excess of aqueous acetic acid. In this process, the same potassium acetate serves repeatedly for conversion into acid acetate, and subsequent decomposition. This process is said to be employed by manufacturers on a large scale in some parts of the continent of Europe. It originated with Melsens.

Acidum Aceticum.—*U. S.*, *Br.* (sp. gr. 1.045, *U. S.*, 1.044, *Br.*). *Acetic Acid.*—This is the acid resulting from the purification of the crude acetic acid obtained by the destructive distillation of wood. It is the acid most useful to the apothecary, and is employed in making numerous pharmaceutical preparations. As this grade of acid has its source in the impure acetic acid it will be proper to premise some account of the crude acid, called *pyroligneous acid*.

Wood, when charred, yields many volatile products, among which are an acid liquor, an empyreumatic oil, and tar containing creosote and some other proximate principles. When the carbonization is performed in closed vessels, these products, which are lost in the ordinary process of charring, may be collected, and, at the same time, a large amount of charcoal be obtained.

Senff has furnished some comparative results in respect to the dry distillation of wood. The points worked out are a comparison of the products of distillation under similar conditions yielded by wood from various parts of the same trees, and from the same wood in a healthy and in an unsound state; also a comparison of the products from one and the same wood distilled slowly or rapidly. It has been found that when similarly distilled the yield by weight of crude acid, tar, charcoal, and gas from the most diverse species of wood does not essentially differ, but that the percentage of real acid in the crude acid obtained varies considerably, and in this respect the

wood from ordinary foliage trees compares favorably with that from needle-leaved trees; also that stem-wood yields more acid than branch-wood, that wood yields more acid than bark, and that sound wood yields more acid than unsound wood. (*Ber. d. Chem. Ges.*, xviii. p. 60; *P. J.*, 1885, p. 696.)

Crude pyroligneous acid, sometimes called *pyroligneous vinegar*, is a dark brown liquid, having a strong smoky odor, and consists of acetic acid, diluted with more or less water, and holding in solution some creosote and empyreumatic oil, with methyl alcohol. It is from this crude acid that the U. S. and British acetic acid, corresponding to the acetic acid of commerce, is obtained. The purification is effected as follows: the acid is saturated with milk of lime, whereby calcium acetate is formed in solution, and thus most of the tarry matter is precipitated. The solution of calcium acetate is then mixed with a concentrated solution of sodium sulphate, and, by double decomposition, sodium acetate is formed in solution, and calcium sulphate precipitated. The solution of sodium acetate is next subjected to evaporation, during which further impurities that separate on the surface are skimmed off. The solution, being duly concentrated, is set aside to crystallize, and the impure salt thus obtained, after having been partially purified by solution and recrystallization, is fused in an iron vessel, stirred until it dries, and, the heat being carefully raised, subjected to incipient carbonization, whereby remaining empyreumatic matters are carbonized, with little damage to the salt. The mass is then dissolved in water, and the solution, being strained and recrystallized, furnishes pure sodium acetate. (See *Sodii Acetas*.) Finally, this salt, distilled with from 34 to 35 per cent. of its weight of sulphuric acid, yields the acetic acid of commerce, the residue being sodium sulphate, which is reserved for decomposing fresh portions of calcium acetate. The acid has still an empyreumatic flavor, which is removed by filtering it through animal charcoal or rectifying with potassium dichromate. The odor is due to *furfural*, $C_5H_4O_2$, which, as Victor Meyer has shown, can be detected even in glacial acetic acid by the red coloration it gives with aniline. It may be removed from pyroligneous acid by agitating the liquid with 2 or 3 per cent. of benzene. The aqueous layer, after separation from the benzene, is stated to give, by a single distillation, a palatable table vinegar.

Acetic acid, according to E. R. Squibb, improves very much by age, and a sample examined for odor when freshly distilled would not be recognized as the same three months afterward.

An excellent quality of acetic acid was made by E. R. Squibb by an improvement on the process of Schwartz, the principal feature being the careful regulation of the heat, whereby the excessive charring of the wood is prevented and the formation of the tarry substances so

reduced as to leave the acetic acid almost entirely free from empyreuma. The retorts, which are rectangular in shape, are supported by wheels secured to shafts, rotating in bearings connected with the sides, and are run upon car tracks into the ovens, after they have been loaded with some billets of oak wood from the transfer car, in an ingenious and simple manner. In the construction of the ovens, care is taken to economize the fuel and to secure control of the temperature by the use of corrugated bottoms to the retorts and dampers in the flues; when necessary, the vapors are condensed in earthenware air condensers. Experience has shown that the production and liberation of acetic acid take place at a considerably lower temperature than that sufficient to convert the wood into charcoal, Squibb having proved that wood begins to char at 218.3° C. (425° F.); indeed, the wood which is removed from the retorts after the operation is over is sold as kindling wood, and has the color of black walnut. The crude acetic acid does not require the tedious method of purification usually employed, but is treated with soda ash, forming sodium acetate, which is decomposed by sulphuric acid, and the acetic acid recovered in a purified condition by distillation.

The sp. gr. of the different acetic acids increases with their strength up to the density of 1.0679 at 25° C. (maximum), after which it decreases until it reaches 1.0472 at 25° C. the density of the strongest acid (*glacial acid*).

It will be noticed, however, upon an examination of the official table (pp. 14-15) that the specific gravities of the glacial (100 per cent.) and the 39 per cent. acid are practically the same, and that the 74 and 81 per cent. and the 76, 77, and 78 per cent. acids have exactly the same density, the variations between 71 and 83 per cent. being very slight. It will thus be seen that specific gravity cannot be relied upon as a criterion for strength. The glacial acid may, however, be distinguished from the 39 per cent. acid by adding 10 per cent. of water, when, if the density increases, the specimen is the stronger acid.

Acidum Aceticum Dilutum.—*U. S.*, *Br.* *Diluted Acetic Acid.*—"Acetic Acid, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, five hundred grammes [or 17 ounces av., 279 grains], to make six hundred grammes [or 21 ounces av., 72 grains]. Mix them. Specific gravity; about 1.009 at 25° C. (77° F.). It should respond to the tests of purity given under *Acidum Aceticum*. To neutralize 23.8 Gm. of Diluted Acetic Acid should require not less than 24 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 0.25 percent. of absolute Acetic Acid), phenolphthalein T.S. being used as indicator." *U. S.*

"Acetic Acid, $2\frac{1}{2}$ fl. ounces (more exactly, 2.49, Imperial measure) or 1137 grains, or 124.7 cubic centimetres or 130.2 grammes; Dis-

tilled Water, a sufficient quantity. Dilute the Acetic Acid with sufficient Distilled Water to form one pint (Imp. meas.) or one thousand cubic centimetres of Diluted Acetic Acid." *Br.* "Specific gravity 1.006. Each gramme should require for neutralization 7.1 cubic centimetres of a decinormal volumetric solution of sodium hydroxide. It must be free from the impurities indicated under 'Acidum Aceticum.'" *Br.*

Properties.—*Glacial Acetic Acid.* This acid, sometimes called *radical vinegar*, is "a clear, colorless liquid, of a strong, vinegar-like odor, and a very pungent, acid taste. Specific gravity; not above 1.049 at 25° C. (77° F.)." *U. S.* The *U. S.* and *Br.* acids are identical in strength (99 per cent.) but the temperature at which the sp. gr. is taken is 25° C. in the *U. S.* and 15° C. in the *Br.* It possesses the property of dissolving a number of substances, such as volatile and fixed oils (*P. J.*, Sept. 11, 1875), camphor, resins and gum resins, fibrin, albumin, etc. As it attracts humidity from the atmosphere, it should be preserved in well-stoppered bottles. Its combinations with salifiable bases are called acetates. "At a temperature somewhat below 15° C. (59° F.), the Acid becomes a crystalline solid. At 117° to 118° C. (242.6° to 244.4° F.) it boils, evolving inflammable vapors." *U. S.*

"Glacial Acetic Acid should respond to the tests of purity given under *Acidum Aceticum*; but the tint produced by the addition of 2 drops of tenth-normal potassium permanganate V.S. to 2 Cc. of the Acid diluted with 10 Cc. of water, contained in a clean, glass-stoppered bottle, should not be changed to brown within two hours. Introduce into a stoppered weighing-bottle 3 Cc. of Glacial Acetic Acid and weigh accurately. Dilute the Acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 5.958, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Acetic Acid in the latter." *U. S.* "It crystallizes when sufficiently cooled, and remains crystalline until the temperature rises above 60° F. (15.5° C.). Specific gravity 1.058 at 60° F. (15.5° C.), and this is increased by the addition of 10 per cent. of water (distinction from a diluted acid of 46 per cent., which has the same specific gravity). Each gramme diluted with 50 cubic centimetres of water should require for neutralization 16.6 cubic centimetres of the volumetric solution of sodium hydroxide. It must be free from the impurities indicated under 'Acidum Aceticum.'" *Br.* The anhydride was first isolated by C. Gerhardt, who found it to be a limpid liquid, heavier than water, and having the constant boiling point of 138° C. (279° F.). Glacial acetic acid should be kept in carefully stoppered glass containers, as it otherwise loses strength. The test of the British Pharmacopœia for oil of turpentine, which requires that it shall form a clear solu-

tion with an equal volume of glacial acetic acid, seems to be reliable only when the acid has been carefully kept and the test carried out at a temperature varying between 14.4° C. and 16.6° C. (58° F. and 62° F.). (See *P. J.*, 1902, 42, 345, 512.)

Acetic Acid is officially described as "a clear, colorless liquid, having a strong, vinegar-like odor, a purely acid taste, and a strongly acid reaction. Specific gravity: about 1.045 at 25° C. (77° F.). Miscible with water or alcohol in all proportions. When heated, the Acid is volatilized without leaving a residue. On adding to Acetic Acid enough ammonia water to neutralize it or to leave the Acid in slight excess, and then ferric chloride T.S., the liquid will acquire a blood-red color, which is discharged by strongly acidulating with sulphuric acid. When the Acid is slightly supersaturated with ammonia, the liquid should not have a bluish tint (absence of *copper*), nor should any residue be left after evaporating the alkaline liquid on a water-bath (absence of *other fixed impurities*). Acetic Acid diluted with 20 volumes of water should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Acetic Acid diluted with 10 volumes of water should not yield a precipitate or turbidity with barium chloride T.S. (absence of *sulphuric acid*), or with silver nitrate T.S. (absence of *hydrochloric acid*). If 5 Cc. of the Acid be supersaturated with 10 Cc. of ammonia water, and 5 Cc. of tenth-normal silver nitrate V.S. be added, and the mixture boiled for one or two minutes, no dark deposit should be produced (absence of *formic* or *sulphurous acids*). When the Acid is slightly supersaturated with potassium hydroxide T.S., the liquid should not develop a smoky odor or taste. If 5 drops of tenth-normal potassium permanganate V.S. be mixed with 2 Cc. of the Acid, previously diluted with 10 Cc. of water, and contained in a clean, glass-stoppered vial, the pink tint should not change to brown at once, and should not become entirely brown, or free from pinkish-brown, in less than half a minute (limit of *empyreumatic substances*). If 10 Gm. of Acetic Acid be diluted with water to measure 100 Cc., then 59.6 Cc. of this solution should require not less than 36 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Acetic Acid), phenolphthalein T.S. being used as indicator." *U. S.*

The British Pharmacopoeia requires that "each gramme should require for neutralization 5.5 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no residue on evaporation, and no characteristic reaction with the tests for lead, copper, arsenium, chlorides, nitrates, sulphates, and sulphites. It should not darken in color when exactly neutralized with *solution of ammonia* and warmed with *solution of silver nitrate* (absence of formates). 2 cubic centimetres of Acetic Acid diluted with 10 cubic centimetres of *water*

should not immediately discharge the color of one drop of *solution of potassium permanganate*, but at the end of half a minute the mixture should retain a shade of crimson (limit of *empyreumatic matter*)." *Br.*

Of the British acid (sp. gr. 1.044) the strength in hydrogen acetate is 33 per cent. The U. S. official acid is somewhat stronger than the British. In the arts *Acetic Acid No. 8* (sp. gr. 1.040) has long been used; it derives its name from the fact that one part added to sufficient water to make eight parts, by measure, constitutes so-called distilled vinegar, used in pickling; the latter is not equal to the official diluted acetic acid in strength (one-fifth weaker). See *Acidum Aceticum Dilutum*, page 17. Calcium phosphate has been frequently detected in acetic acid sold as pure and was copiously precipitated by ammonia added in excess. (Bruchner, *A. J. P.*, Sept. 1870, p. 389.) Victor Meyer has met with glacial acetic acid contaminated with 0.108 Gm. furfural in a liter. (*Ber. d. Chem. Ges.*, 1878, p. 1870.)

It is difficult to ascertain the strength of acetic acid by saturating it with the carbonated alkalis, when the operator depends upon litmus paper for ascertaining the point of its neutralization. The difficulty is caused by the fact that the potassium and sodium acetates, though neutral in composition, are alkaline to litmus paper. Hence the liquid begins to be alkaline to litmus paper while some free acid yet remains, but insufficient to overcome the alkaline reaction of the salt formed. It follows, therefore, that by the use of litmus paper the strength of the acetic acid will be underrated. The degree of inaccuracy, where litmus paper is used, is much diminished by saturating the acetic acid with a solution of pure calcium saccharate of a known strength, as proposed by C. G. Williams. (*P. J.*, May, 1854, p. 594.) A still better way is to add to the acid a weighed excess of barium carbonate, and to calculate its strength by the amount of the carbonate decomposed, ascertained by deducting the undissolved from the total used. (Redwood.) Equally accurate results may be obtained by the use of calcium carbonate in a similar manner. (E. C. Nicholson and D. S. Price, *Chem. Gaz.*, Jan. 15, 1856.)

Charles F. Squibb has made numerous experiments proving the value of many strengths of acetic acid as menstrua for exhausting the valuable organic principles of drugs by percolation; he found even diluted acetic acid a reliable menstruum. J. P. Remington preferred a 10 per cent. acetic acid, and suggested a class of preparations termed "*acettracts*" to replace solid extracts. Acetic acid is a powerful solvent and can frequently be made to take the place of the more expensive alcoholic menstrua. (*A. J. P.*, 1897, p. 121.)

Uses.—*Crude Pyroligneous Acid.* This acid having been incidentally described as the source of the acetic acid of commerce, it may be

proper in this place to notice its uses. It has been employed as an application to *gangrene* and ill-conditioned *ulcers*. It acts on the principle of an antiseptic and stimulant, the former property being mainly due to the presence of creosote.

The crude acid is advantageously applied to the preservation of animal food. William Ramsey made some interesting experiments with it for that purpose. Herring and other fish, simply dipped in the acid and afterwards dried in the shade, were effectually preserved, and when eaten were found very agreeable to the taste. Herring, slightly cured with salt by being sprinkled with it for six hours, then drained, next immersed in pyroligneous acid for a few seconds, and afterwards dried in the shade for two months, were found by Ramsey to be of fine quality and flavor. Fresh beef, dipped in the acid in summer for a minute, was perfectly sweet in the following spring. Silliman states that one quart of the acid, added to the common pickle for a barrel of hams, at the time they are laid down, will impart to them the smoked flavor as perfectly as if they had been smoked in the ordinary way.

Glacial Acetic Acid.—This acid is used only externally, and acts as a rubefacient, a vesicant, or a caustic, according to the length of time it is applied. Its application requires caution. It is sometimes employed as a substitute for cantharides, when a speedy blister is desired. It may be applied by means of blotting paper or cambric moistened with the acid. It is a good corrosive for the destruction of warts and corns.

Acetic Acid.—This acid is very rarely used internally, but is refrigerant and astringent when sufficiently diluted. Owing to its volatility and pungency, its vapor is frequently applied to the nostrils as an excitant in *syncope*, *asphyxia*, and *headache*. When employed for this purpose, it is generally added to a small portion of potassium sulphate, so as to moisten the salt, and the mixture is put into small glass bottles with ground stoppers.

It is a mild caustic, and has been used in cancer, by injection into the diseased tissue, but the general result has not been favorable. Two or three ounces of it taken internally undiluted very nearly caused death in an adult. (*L. L.*, July, 1867.) The prominent symptoms were, at first, slight collapse, and asphyxia from closure of the glottis. Recovery was secured by tracheotomy; after the reaction, great thirst, salivation, pain in the fauces, and inability to swallow were present, but without serious gastric, pulmonary, or cardiac disturbances.

Diluted Acetic Acid.—The object of making diluted acetic acid official is to possess a weak solution of pure acetic acid which may be substituted for distilled vinegar in all formulas in which nicely is required. For a long period diluted acetic acid has been made by mixing one part of acetic acid with seven parts of water by measure. The official diluted

acid was made considerably stronger in the U. S. P. 1880, and the strength was not altered in the U. S. P. 1890, nor in the 8th Revision. Distilled vinegar contains a little organic matter, which is always darkened or precipitated when its acid is saturated with an alkali, a change which does not take place when diluted acetic acid is employed.

Dose, of diluted acetic acid, twenty to forty minims (1.3 to 2.5 Cc.)

ACIDUM BENZOICUM. U. S., *Br.*

BENZOIC ACID

(ăç'î-dûm bën-zō'î-cûm)

$\text{HC}_7\text{H}_5\text{O}_2 = 121.13$

"An organic acid [$\text{C}_6\text{H}_5\text{COOH}$], obtained from benzoïn by sublimation, or prepared artificially. It should be kept in dark amber-colored, well-stoppered bottles, in a cool place." *U. S.* "Benzoic Acid, $\text{C}_6\text{H}_5\text{COOH}$, is obtained from benzoïn by sublimation. It may also be obtained from toluene, from hippuric acid, and from other organic compounds." *Br.*

Acidum Benzolicum Sublimatum, Flores Benzoes (Flowers of Benzoïn); Acide benzoïque, Fleurs de Benjoïn, *Fr.*; Acidum Benzolicum, *P. G.*; Benzoesaure, Benzoëblumen, *G.*; Acido benzoico, *It.*, *Sp.*

Both the U. S. and *Br.* Pharmacopœias have omitted processes for the preparation of benzoic acid.

Formerly the benzoïn before sublimation was mixed with sand; but this is now usually omitted, as not only useless, but probably injurious by favoring the production of empyreumatic substances. The acid, which exists in the benzoïn combined with resin, is volatilized by the heat, and condensed in the upper part of the apparatus. Unless the temperature be very carefully regulated, a portion of the resin is decomposed, and an oily substance generated, which rises with the acid, and gives it a brown color, from which it cannot be entirely freed by bibulous paper; and this result, even with the greatest caution, sometimes takes place. The process for subliming benzoic acid may be conducted in a glazed earthenware vessel, capped by a cone of paper, or by another vessel with a small opening at the top, and a band of paper pasted round the place of junction. After the heat has been applied for an hour, the process should be suspended until the sublimed acid is removed from the upper vessel or paper cone, when it may be renewed, and the acid again removed, and thus alternately until colored vapors rise. Mohr, after experimenting, recom-

mended the following plan as unobjectionable. In a round cast iron vessel, eight or nine inches in diameter and two inches deep, a pound or less of coarsely powdered benzoin is placed, and uniformly strewn over the bottom. The top of the vessel is closed by a sheet of bibulous paper, which is secured to the sides by paste. A cylinder of thick paper in the form of a hat, just large enough to fit closely around the sides of the pot, is then placed over it, and in like manner secured by paste. A moderate heat is now applied by means of a sand bath, and continued for three or four hours. The vapors pass through the bibulous paper, which absorbs the empyreumatic oil, and are condensed within the hat in brilliant white flowers, having an agreeable odor of benzoin. (*Ann. Pharm.*, xxix. 178.) The process official in U. S. P. 1870 was based upon Mohr's, but it frequently happens that the sublimed crystals, after they have formed in the cap, and while the sublimation is still going on, fall upon the bibulous paper, and if this paper should happen to be heated to only 120° C. (248° F.) the crystals will melt, and soon stop up the pores of the paper. If coarse muslin be substituted for the bibulous paper, it serves the purpose of retaining any empyreumatic substances, and yet permitting the vapors to pass through without becoming glazed by a deposit of melted acid. Strips of paper passed at irregular intervals across the cap prevent the falling back of crystals. The remaining acid of the benzoin may be extracted, if deemed advisable, by treating the residue of the balsam with lime or sodium carbonate. From the mode of preparing benzoic acid by sublimation, it was formerly called *flowers of benzoin*.

Another mode of separating the acid from benzoin is by combining it with a salifiable base and precipitating with an acid. Such is the process of Scheele. It consists in boiling the powdered benzoin with calcium hydroxide and water, filtering the solution of calcium benzoate thus obtained, and precipitating the benzoic acid with hydrochloric acid. In order to get the benzoic acid in the ordinary form, it has been proposed to sublime the acid after its precipitation.

Several other modes of extracting the acid have been recommended. The following is the process of Stolze. One part of the benzoin is dissolved in three parts of alcohol, the solution filtered and introduced into a retort, and the acid saturated by sodium carbonate dissolved in a mixture of eight parts of water and three of alcohol. The alcohol is distilled off and the sodium benzoate contained in the residuary liquid is decomposed by sulphuric acid, which precipitates the benzoic acid. This is purified by solution in boiling water, which lets fall the acid when it cools. By this process Stolze obtained 18 per cent. of acid from benzoin containing 19.425 per cent. By the process of Scheele he obtained 13.5 per cent.; by the agency of sodium carbonate, 12 per cent.; by

sublimation, only 7.6 per cent. Scharling prepared benzoic acid by means of heated steam, and obtained 8 per cent. (*A. J. P.*, xxiv. 236.)

The acid is manufactured very cheaply by synthetic methods. The two most commonly employed are those which start either with *toluene*, $C_6H_5CH_3$, or *naphthalene*, $C_{10}H_8$. In the first method the toluene is changed to benzo-trichloride, $C_6H_5.CCl_3$, and this, heated with water to 150° C. (302° F.) in closed vessels, generates benzoic acid according to the reaction:

By the second method naphthalene is changed first into naphthalene tetrachloride, and this by the action of nitric acid into phthalic acid, $C_6H_4(COOH)_2$. This is converted into a calcium phthalate and strongly heated with calcium hydroxide, whereby the phthalate is converted into calcium carbonate and benzoate; this latter salt is then treated with hydrochloric acid, and the benzoic acid thus set free. This acid is frequently resublimed in contact with benzoin, in order to give it the vanilla-like odor of the acid sublimed from the gum. A method of making benzoic acid from tannin or gallic acid is described in *Ph. Era*, 1892, 172. P. Schulze produced benzoic acid by heating benzal chloride or benzo-trichloride in the presence of ferric benzoate or metallic iron. The process is patented. (*Ph. Centralh.*, 1896, 221.)

Under the name of *German benzoic acid*, there was at one time imported into the United States benzoic acid prepared from the urine of cattle and horses by treating it with milk of lime and boiling the calcium hippurate with hydrochloric acid. By boiling the hippuric acid thus separated, with hydrochloric acid, it is split into benzoic acid and glyco-coll, according to the reaction:

It is white, has a fine lustre, and is said to be very pure, but sometimes has a slight urinous odor indicative of its origin. (*A. J. P.*, xxvii. 23; *P. J.*, July, 1875.) Owing to the scarcity in the market of benzoin yielding paying quantities of benzoic acid, it was asserted that the English manufacturers used certain varieties of Botany Bay gum (*Gum acroides*), and obtained a larger yield of an acid which was at one time regarded as cinnamic, but has been shown to be benzoic acid. (*N. R.*, Feb. 1879.)

Properties.—Sublimed benzoic acid is in "white, or yellowish-white, lustrous scales or friable needles, nearly odorless, or having a slight characteristic odor resembling that of benzoin, and an acid, pungent taste; somewhat volatile at a moderately warm temperature, and acquiring a yellow color on exposure to light." *U. S.* From solution the acid crystallizes in transparent prisms. When quite pure it is inodorous; but prepared by sublimation from the balsam it has a peculiar, agreeable, aromatic odor, dependent on the presence of an oil, which may be separated by dissolving the acid in alcohol and precipitating it with water. Its taste is

warm, acrid, and acidulous. It is unalterable in the air, but at 121.6° C. (251° F.) melts, and at a somewhat higher temperature rises in suffocating vapors. Sp. gr. 1.29. The Br. Pharmacopœia gives as its melting point 121.4° C. (250.5° F.); "but when obtained from benzoin, it melts at about 248° F. (120° C.), forming a yellowish liquid which becomes brownish but not red as the temperature rises (absence of hippuric acid), and boils at about 462° F. (238.9° C.). When heated to the last-named temperature, it passes off in vapor which burns with a bright-yellow flame, and leaves only a slight residue."

Br. It is inflammable, burning without residue. One hundred parts of 90 per cent. alcohol dissolve about forty parts, while the same quantity of pure ether will dissolve about thirty parts. (Bourgoin.) The addition of borax or sodium phosphate increases its solubility. It is readily dissolved by alcohol, and by concentrated sulphuric and nitric acids, from which it is precipitated by water. "Soluble in 281 parts of water and in 1.8 parts of alcohol at 25° C. (77° F.); in 15 parts of boiling water, and in 1 part of boiling alcohol; also soluble in 3 parts of ether, 7 parts of chloroform, and readily soluble in carbon disulphide, benzene, fixed and volatile oils; sparingly soluble in petroleum benzine." *U. S.* "It is soluble in 400 parts of cold or 17 parts of boiling water, in its own weight of absolute alcohol, in 3 parts of alcohol (90 per cent.), in 2.5 of ether, in 7 of chloroform, and in the fixed and volatile oils; also in solutions of the alkalies and of calcium hydroxide, forming benzoates, and it is precipitated from these on the addition of hydrochloric acid unless the solutions are very dilute." *Br.* It is entirely soluble in solutions of potassium, sodium, or ammonium hydroxides, from which it is precipitated by hydrochloric acid. On carefully neutralizing any of these solutions and adding solution of ferric sulphate previously diluted with water, a flesh-colored precipitate is produced. Its solution reddens litmus paper, and with salifiable bases it forms salts called benzoates.

"Benzoic Acid volatilizes freely with the vapor of water. On heating it to 100° C. (212° F.), it begins to sublime. At 121.4° C. (250.5° F.) it melts, and at a higher temperature it is consumed without leaving a residue. The acid sublimed from benzoin has a lower melting point, and a greater solubility in water, than that prepared artificially. An aqueous solution of Benzoic Acid colors blue litmus paper red. On heating Benzoic Acid gradually with 3 parts of freshly slaked lime in a dry test-tube, benzene is evolved. Benzoic Acid is freely soluble in solutions of alkali hydroxides. On carefully neutralizing such a solution, and adding ferric chloride T.S., previously diluted with 2 volumes of water, and neutralized, if necessary, by ammonia water, a flesh-colored precipitate of ferric benzoate is produced. A solution of Benzoic Acid in pure, cold sulphuric acid, when gently warmed, should not turn

darker than light brown; if it is then poured into water, the Benzoic Acid should separate as a white precipitate, and the liquid should be colorless (absence of readily carbonizable, organic matters). If 0.5 Gm. of the Acid and 0.8 Gm. of calcium carbonate be mixed with a little distilled water in a crucible, the mixture dried, gently ignited, and then dissolved in 20 Cc. of distilled water, with the aid of nitric acid in slight excess, and filtered, the addition of silver nitrate T.S. should not produce much more opalescence than is produced by the same quantity of the same reagent in a solution measuring 20 Cc., prepared by dissolving 0.8 Gm. of the same calcium carbonate in distilled water with the aid of nitric acid (absence of more than traces of chlorine). On warming 0.5 Gm. of the Acid with 5 Cc. of water, and 0.5 Gm. of potassium permanganate in a test-tube, loosely stoppered, and placing it in a water-bath heated to about 45° C. (113° F.) for about ten minutes, then tightly stoppering, and cooling the test-tube with cold water, upon removing the stopper, no odor of oil of bitter almond should be discernible (absence of cinnamic acid)." *U. S.* "When 0.5 gramme is heated in a closed crucible with twice its weight of calcium carbonate, the mass dissolved in diluted nitric acid, and solution of silver nitrate added, only the slightest cloudiness should result (absence of chlorobenzoic acid). It should yield no characteristic reaction with the tests for oxalates. It should not develop the odor of benzaldehyde when warmed with its own weight of potassium permanganate and ten times its weight of diluted sulphuric acid (absence of cinnamic acid). 0.2 gramme suspended in 10 cubic centimetres of water should not immediately discharge the color of two drops of solution of potassium permanganate (absence of hippuric and cinnamic acids)." *Br.*

Benzoic acid is a characteristic constituent of the balsams, and has been found in vegetable and animal products. When heated, it should sublime without residue; but the *Br. Pharm.* allows a slight residue for impurities.

Potassium permanganate has been depended upon more than any other reagent to distinguish between benzoic acids as obtained from different sources. Schacht proposes the following test: if 3 grains of benzoic acid be dissolved in 96 minims of solution of potassium hydroxide, sp. gr. 1.777, diluted with 96 minims of distilled water, and 10 drops of a solution made by dissolving 1 grain of potassium permanganate in 200 grains of water be added to it and the whole heated to boiling, dark green liquids (in which brown precipitates gradually appear) are produced if the benzoic acid be obtained from urine, from toluene, or from commercial benzoin, while if the benzoic acid be from Siam benzoin (sublimed or made by wet process) decoloration of the liquids and brown precipitates are produced, due to the presence of cinnamic acid. (*Ph. Centralh.*, 1881, 565.)

The odor of bitter almonds confirms the presence of cinnamic acid. Essell (*Ph. Ztg.*, 1904, 272) modifies this test to secure greater accuracy as follows: 0.2 Gm. of the finely powdered benzoic acid and 5 Ce. of tenth-normal permanganate solution are mixed in a test tube of wide diameter and securely corked. When the red color is discharged (usually after a few minutes) 5 Ce. more of tenth-normal permanganate solution are added, and the tube is set aside from 15 to 30 minutes, with frequent shaking. If then the cork be removed the odor of benzaldehyde will be strongly perceptible in the presence of 5 per cent. of cinnamic acid, and distinctly recognizable if only 1 per cent. is present. It is claimed that benzoic acid from benzoïn can be distinguished from that from other sources by adding resorcinol and sulphuric acid to the alcoholic solution of the acid; the benzoïn-benzoic acid gives a beautiful red color, due probably to a trace of vanillin or other aldehyde in the natural product. (Göldner, *Ph. Ztg.*, 1892, 697.)

Uses.—Benzoic acid is irritant to the alimentary mucous membrane, and as a stimulant expectorant is of some value in *chronic bronchitis* and the later stages of the acute disorder. Led by his belief that it has the power of converting uric acid into hippuric acid, Alexander Ure many years ago proposed benzoic acid as a remedy for the dissolving of deposits of the urates, but it is now proved that the hippuric acid which appears in the urine of those taking benzoic acid is formed out of the benzoic acid itself. This conversion would appear to take place in the kidneys, since, after the exhibition of large doses, benzoic and not hippuric acid can be detected in the blood, while even small amounts of hippuric acid injected into the blood produce violent poisoning. Moreover, Bunge and Schmiedeberg have succeeded in converting benzoic acid into hippuric acid by passing blood containing benzoic acid slowly through the kidneys immediately after their removal from the body. In rare cases, according to Meissner and Shepard, the benzoic acid is converted into succinic instead of hippuric acid. When it is given very freely a portion of the benzoic acid escapes unchanged. Where the nitrogen necessary for the conversion of the benzoic into hippuric acid comes from, is at present unknown. *A priori* it would seem probable that the source of this nitrogen was the urea, but the testimony as to the effect of the injection of benzoic acid upon the urea and uric acid of the urine is entirely contradictory. Investigators are about equally divided in their findings that the uric acid is very much diminished, and that it remains normal; a fact which is also true of urea. In our own experience benzoic acid has seemed to be a very useful remedy in the treatment of *uric acid gravel*, though without specific influence on the uric acid diathesis.

The urine is always strongly acidified by the free administration of benzoic acid, so that the

remedy is useful in *phosphatic gravel* and in *ammoniacal cystitis* with a tendency to a deposit of the phosphates. Its beneficial influence, of course, continues only during its administration, and it is necessary to give it in very large doses—up to a drachm a day. It has been strongly recommended in *nocturnal incontinence*, and has also sometimes been given with advantage in various forms of *cystitis* and even in acute *gonorrhœa*. As first pointed out by Dougall in 1872, benzoic acid is a powerful antiseptic. Bucholz found that 0.2 per cent. of it has a decided influence upon the development of the organisms of putrefaction; and F. Baden Benger (*P. J.*, 1875, p. 211) states that one-fourth of a grain of it added to a fluidounce of infusion of orange, buchu, or gentian will cause the infusion to keep unchanged for at least one month.

Benzoic acid and benzoates (notably sodium benzoate) are ingredients in many antiseptic preparations. Patented preservative mixtures containing benzoic acid are numerous. A maximum (one-fourth of one per cent.) of sodium benzoate is now allowed by law in the State of Pennsylvania for use as a preservative in fruit juices and syrups. Benzoic acid may be administered in pill, using soap as an excipient. It is an ingredient in some cosmetic washes, and has been employed by way of fumigation as a remedy in affections of the skin. It has also been employed as a local hæmostatic, in connection with alum, with considerable asserted success; but there can be little doubt that alum is the more efficient ingredient.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

ACIDUM BORICUM. *U. S.*, *Br.*

BORIC ACID [Boric Acid]

(ăc'î-dûm bô'rî-cûm)

$H_3BO_3 = 61.54$

"It should contain not less than 99.8 per cent. of pure Boric Acid [$B(OH)_3$]." *U. S.* "A weak acid having the formula H_3BO_3 . Obtained by the interaction of sulphuric acid and borax, and by the purification of native boric acid." *Br.*

Hydrogen Borate; Acidum Boracicum; Boracic Acid; Acide Borique Cristallisé, *Fr. Cod.*; Acidum Boricum, *P. G.*; Borssaure, *G.*; Acido bórico, *It., Sp.*

Boric acid occurs in small amount, most probably in combination as a magnesium salt, in sea water and in certain mineral waters, as the hot springs of Wiesbaden, Aix-la-Chapelle, and Vichy; in certain mineral substances, such as the *borocalcite* which occurs in considerable quantities in the nitre beds of Chili; in the natural borax or *tincal*, first found in the basins of dried-up lagoons in Central Asia, and afterwards in large amount in Clear Lake, Cali-

fornia; in *ulexite* (sodium and calcium borate) and *colemanite* (calcium borate). The last of these minerals now yields by far the largest amount of the boric acid obtained on the Pacific coast. It is found in a large vein deposit in San Bernardino County, California, where it is mined and shipped to the works of the Borax Consolidated Co. (Limited), at Alameda, California. Boric acid itself is extracted, under the name of *sassolin*, from the lagoons of the volcanic districts of Tuscany, and from the crater of Vulcano, one of the Lipari Islands.

Preparation.—In the neighborhood of Monte Rotondo, Lago Zolfozero, Sasso, and Larderello are found numerous hillocks and fissures, the latter of which emit hot aqueous vapor containing boric acid and certain gases. Around one or several of these fissures, called *suffioni*, a circular basin of masonry is built, which is filled with water and called a lagoon. By the jets of vapor constantly breaking through it, the water becomes gradually impregnated with boric acid and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapor, where it is sufficiently concentrated to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid thus obtained contains from 74 to 84 per cent. of boric acid, the impurities consisting chiefly of alum, the double ammonium and magnesium sulphate, and calcium sulphate. The production of Tuscan boric acid for the year 1902 was stated to be 2763 metric tons, while that for 1903 amounted to 2583 metric tons.

About 9000 metric tons of a calcium borate known as *pandermite* were produced in Turkey in 1903, while Chili is credited with having exported 15,734 tons of calcium borate in the same year.

The native borax minerals of California supply, at present, the entire American demand for boric acid. The American production of refined borax including boric acid for the year 1902 was 18,152 metric tons, valued at \$2,536,614. The production of crude borax in the United States for the year 1904 was 41,422 metric tons.

Properties.—"Transparent, colorless scales, of a somewhat pearly lustre, or six-sided, triclinic crystals, or a light, white, very fine powder, slightly unctuous to the touch; odorless, having a faintly bitter taste, and permanent in the air. Boric Acid is soluble in 18 parts of water, 15.3 parts of alcohol, and 4.6 parts of glycerin at 25° C. (77° F.); in 3 parts of boiling water and 4.3 parts of boiling alcohol. The addition of hydrochloric acid decreases its solubility in water." *U. S.* "Soluble in 30 parts of cold water, in 4 of glycerin, in 30 of alcohol (90 per cent.), and in 3 of boiling water." *Br.* Boric

acid has a sp. gr. of 1.434, dissolves in three parts of boiling water and in volatile oils, but is insoluble in ether. On evaporation of the alcoholic solution, the boric acid volatilizes even more readily than from the aqueous solution. Glycerin, when heated, dissolves a very large quantity of boric acid. (See *Glyceritum Boroglycerini*; also *Boroglyceride*, PART II.) Its aqueous solution tastes somewhat acid, colors litmus paper a wine red, and changes turmeric paper to a brown color, analogous to that produced by alkalies, even when hydrochloric acid is present. On moistening the paper so browned and then dried with caustic alkali solution, it turns first blue and then a dirty gray color. Cassol and Gertraud (*Chem. News*, 1903, 27) use *curcumin* with oxalic acid for determining the presence of boric acid when used as a preservative for foods. "When heated to 100° C. (212° F.), Boric Acid loses water, forming metaboric acid (HBO_2), which slowly volatilizes at that temperature. Heated to 160° C. (320° F.), it fuses to a glassy mass of tetraboric (or pyroboric) acid ($\text{H}_2\text{B}_4\text{O}_7$); at a higher temperature the fused mass swells up, loses all of its water, and becomes boron trioxide (B_2O_3), which fuses into a transparent, hygroscopic, non-volatile mass. Boric acid readily volatilizes from a boiling aqueous solution. Its solution in alcohol or glycerin, when ignited, burns with a flame enveloped with a green-colored mantle. An aqueous solution of Boric Acid (1 in 50) colors blue litmus paper red, and yellow turmeric paper brownish-red after drying, even when the solution has been acidulated with hydrochloric acid; this brownish-red color is changed to bluish-black by ammonia water. If 1 Gm. of Boric Acid be added to 10 Cc. of boiling alcohol in a test-tube, complete solution should result." *U. S.* "It changes the color of *litmus* to wine-red in the cold, a hot saturated solution giving a bright red color; *turmeric paper* moistened with an aqueous solution, even when slightly acidulated with *hydrochloric acid*, becomes brownish-red on gently drying, and this color changes to a greenish-black, if *solution of potassium hydroxide* be added. The solution in *alcohol* burns with a flame tinged with green, especially when the solution is acidulated with *sulphuric acid*. Boric Acid liquefies when warmed, and on careful heating loses 43.6 per cent. of its weight, the product solidifying, on cooling, to a brittle glass-like mass. It should yield no characteristic reaction with the tests for lead or copper, and only the slightest reactions with the tests for iron, calcium, magnesium, potassium, sodium, ammonium, chlorides, and sulphates." *Br.*

Boric acid is a weak acid, or may even act as a base. Thus, with sulphuric and phosphoric acids it forms compounds which may be considered as salts. Its compounds with bases, when in solution, are readily decomposed by other acids, but at red heat boric oxide will displace many of the stronger but more volatile acids. "The aqueous solution of the Acid

(1 in 25) should not be precipitated by barium chloride T.S. (absence of *sulphates*); by silver nitrate T.S. with nitric acid (absence of *chlorides*); by ammonium oxalate T.S. (*calcium*); or by sodium phosphate T.S. and ammonia water (*magnesium*), or respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). 5 Cc. of the saturated aqueous solution should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). In a solution of 1 Gm. of Boric Acid in a mixture of 1 Cc. of hydrochloric acid and 49 Cc. of water, 0.5 Cc. of potassium ferrocyanide T.S. should not at once produce a blue color (limit of *iron*). One Gm. of Boric Acid, when dissolved in 50 Cc. of distilled water, after the addition of 50 Cc. of glycerin, should require not less than 16.2 Cc. of normal sodium hydroxide V.S., for neutralization (corresponding to at least 99.8 percent. of Boric Acid), phenolphthalein T.S. being used as indicator." *U. S. Sch uffele* of Paris, has drawn attention to a commercial boric acid containing lead. (*N. R.*, July, 1877).

Boric acid requires 18 parts of cold water to dissolve it, and this fact has led to many attempts to increase its solubility without interfering with its usefulness. The use of glycerin has been officially sanctioned. Scholz and Mansier recommend the use of magnesium carbonate (11 per cent.), but such an addition is not always permissible. When equal parts of boric acid and borax are dissolved in boiling water a crystalline mass separates on cooling, which has been termed *boro-borax*. Its advantages are increased solubility and neutral reaction. The remarkable volatility of boric acid when in alcoholic solution has been observed by Schneider and the fact utilized in its quantitative determination. (*Zeit. Oest. Apoth. Ver.*, 1896, 791.)

Uses.—The physiological action of boric acid and its salts is feeble, yet severe and even fatal cases of poisoning from it have been reported. The symptoms have been great depression of spirits, fall of bodily temperature, a pulse which is either rapid or slow but always very feeble, nausea, violent vomiting, hiccough, sometimes an erythematous eruption accompanied with much oedematous swelling, ecchymoses, disturbance of respiration, and, very late in the poisoning, coma followed by death. The acid escapes rapidly from the system, and to some extent through all the secretions, but especially by the urine. It has been demonstrated by E. T. Stewart and H. C. Wood to act as a depressant upon the spinal centres, and also to have a depressant influence upon the heart itself.

Boric acid and its salts are usually poisonous to the lower forms of life, and have considerable antiseptic power, but the experiments of Sternberg and of Andrews have shown that this influence is too feeble to be depended upon against pathogenetic germs. The acid acts upon mucous membranes as a soothing detergent, is

nearly free from irritating properties, and is much used as a local application in mucous membrane inflammations, such as *conjunctivitis*, *aphthous ulceration of the mouth*, and even *diphtheria*.

In antiseptic surgery the remedy has been tried, but has failed to take rank with more powerful agents. Lint saturated with an aqueous solution, or an ointment produced by melting one part each of spermaceti and white wax with six parts of vaseline and adding while hot two to four parts of a saturated glycerite of boric acid, may be used. In treating wounds, it is often desirable to use a solution containing more than 4 per cent. of boric acid (about the extent of its solubility in water). Jaenicke proposes for this purpose a mixture of equal parts of boric acid and borax, of which 16 per cent. is soluble in water at ordinary temperature. It is said to be non-irritating, non-poisonous, and efficacious; being soluble to the extent of 30 per cent. in water at the temperature of the blood, the solution can be applied to the interior of organs; on cooling, the crystals of the acid salt separate. (*A. J. P.*, 1892, 97.) In *ammoniacal cystitis* boric acid may be given internally, and the washing out of the bladder with a saturated solution of the acid or of borax often acts most happily.

Of the acid, ten grains (0.65 Gm.) may be given three times a day; strength of the solution for use on the conjunctiva or other mucous membrane, from five grains to the ounce up to saturation. Fatal cases of boric acid poisoning have been produced by the immoderate use of its solution in washing out internal cavities. Two ounces of boric acid in the vagina produced violent poisoning, but the patient recovered. The question of the use of boric acid as a food preservative has been the cause of a good deal of dispute and is as yet hardly definitely determined. It has certainly been proven that very large doses of boric acid may be taken without serious poisoning. Maass indeed affirms that common salt is twice as toxic, at least for the frog. Cyon found that borax may be given to a dog up to 180 gr. a day without disturbing the general nutrition. On the other hand the statements of Liebreich, that it is without harmful influence upon the kidney, has been denied by Harrington. As the result of an elaborate study under the auspices of the United States Department of Agriculture, H. A. Wiley concluded that while small quantities of boric acid or borax up to a half gramme daily can be taken for a short period of time without detriment to health, the long continued use of even a small dose causes disturbances of appetite and digestion. There was also constantly a loss of weight which Wiley attributed to failure in assimilation on account of digestive disturbances. The habitual use of any preserved food is certainly not advantageous, but that boric acid is distinctly more deleterious than saltpetre does not seem to be demonstrated.

For the detection of boric acid in food products see *Chem. News*, 1903, 27; *A. Pharm.*, 1904, 194; *J. Am. C. S.*, 1904, 91.

The tendency of the crystals of boric acid to slip from under the pestle renders the process of pulverization very tedious. It is essential that the acid be in an impalpable powder when it is desired to make an ointment. The gradual addition of ether to the acid has been suggested as a valuable aid to trituration. Manufacturers at the present time supply boric acid made by precipitation in an impalpable powder. Boric acid ointment (Lister's) is made from one part each of boric acid and white wax, and two parts each of oil of sweet almond and paraffin.

Dose, of boric acid, five to ten grains (0.32 to 0.65 Gm.).

ACIDUM CAMPHORICUM. U. S.

CAMPHORIC ACID

(ăc'f-dŭm cām-phōr'ī-cŭm)

"A dibasic organic acid [$\text{C}_8\text{H}_{14}(\text{COOH})_2$], obtained by the oxidation of camphor." *U. S.*

Acide camphorique, Fr.; Acidum camphoricum, P. G.; Kamphorsäure, Kamphylsäure, Kamphersäure, G.

This acid is obtained by the oxidation of camphor by heating it with nitric acid, and purifying the crystals so obtained. On further oxidation it is changed into *camphoronic acid*, $\text{C}_8\text{H}_{14}\text{O}_6$. It has been made synthetically by Komppa (*P. J.*, 1904, 77).

Properties.—It occurs in "colorless, odorless, monoclinic prismatic crystals or plates; melting at 187°C . (368.6°F .); at a higher temperature yielding an anhydride, and ultimately decomposing without leaving any weighable residue. Soluble in 125 parts of water at 25°C . (77°F .), and in 10 parts of boiling water; readily soluble in alcohol, less soluble in ether and chloroform; soluble in fatty oils. Camphoric Acid is dextro-rotatory, showing, in 10 percent. alcoholic solution, the value $[\alpha]_D = +47.8^\circ$. The aqueous solution reddens blue litmus paper. If 2 Cc. of a saturated aqueous solution of Camphoric Acid be mixed with 2 Cc. of sulphuric acid in a test tube, and 1 Cc. of a solution made by dissolving 1 Gm. of ferrous sulphate in 2 Cc. of diluted sulphuric acid be poured carefully upon it, no dark-colored zone should develop at the line of contact (absence of *nitric acid*)." *U. S.*

Uses.—Camphoric acid, when taken internally, is rapidly absorbed and eliminated from the kidneys. When given in overdose it is capable of producing both gastric and renal irritation. Originally proposed by Fürbringer as an intestinal disinfectant in *tubercular* and other *intestinal catarrhs*, it has been used to some extent

in *cystitis*, but is especially employed in the treatment of *night sweats*; thirty to forty-five grains (2 to 3 Gm.) of it may be administered in twenty-four hours if necessary.

Dose, five to fifteen grains (0.32 to 1.0 Gm.).

ACIDUM CITRICUM. U. S., Br.

CITRIC ACID

(ăc'f-dŭm cit'rī-cŭm)

"A tribasic organic acid [$\text{C}_6\text{H}_4(\text{OH})(\text{COOH})_3 + \text{H}_2\text{O}$], usually prepared from the juice of limes or lemons. It should contain not less than 99.5 percent. of pure Citric Acid." *U. S.* "Citric Acid, or hydrogen citrate, $\text{C}_6\text{H}_4\text{OH}(\text{COOH})_3 \cdot \text{H}_2\text{O}$, may be obtained from the juice of the fruit of various species of *Citrus*." *Br.*

Acidum Citri, s. Limonis, s. Limonum, s. Limonorum; Acidum citricum, P. G.; Citronensäure, Citronsaure, G.; Acide citrique, Fr. Cod.; Acide du Citron, Fr.; Acido citrico, It., Sp.

Citric acid is the peculiar acid to which limes and lemons owe their sourness. It is present also in the juice of other fruits, such as the cranberry, the red whortleberry, the berry of the bittersweet, the red gooseberry, the currant, the strawberry, the raspberry, the tamarind, and the red elderberry (fruit of *Sambucus racemosa rubra*). The latter berry contains citric acid so abundantly that it has been proposed as a source of the acid by Thibierge, of Versailles. It is contained also largely in the fruit of *Cyphomandra botacea*, a solanaceous plant, indigenous in Mexico, Peru, and other parts of South America, where it is called *tomato de la paz*. The commercial source of citric acid is lime, lemon, and bergamot juice; large quantities of *lime juice* are made in Sicily, concentrated, and exported to England and the United States.¹ Citric acid, which was formerly imported in large quantities from Great Britain, is now made extensively in the United States.

The acid is extracted from lemon or lime juice by a very simple process, for which we are indebted to Scheele; it is one requiring some careful manipulation. The boiling juice is first completely saturated with calcium car-

¹ The composition of some of these commercial lime juices is given by Allen (*Com. Org. Anat.*, 2d ed., vol. I., 458), as follows:

	Density.	Oz. Free Acid per gallon.	Oz. Combined Org. Acid per gallon.
Lime juice:			
Raw Sicilian		6 to 9	0.85
Raw English	1.04 to 1.05	11 to 13	0.3
Concentrated	1.20 to 1.25	56 to 72	6 to 8
Bergamot juice:			
Concentrated	1.22 to 1.25	47 to 55	7 to 8
Lemon juice:			
Raw	1.035 to 1.04	10.6 to 13.5	0.4 to 0.7
Concentrated	1.28 to 1.38	82 to 112	8.6

See *Limonis Succus* and also paper by D. H. Hassler, *A. J. P.*, 1886, p. 14.

bonate (chalk or whiting) in fine powder, and the calcium citrate thus formed is allowed to subside. This is then washed repeatedly with water, and decomposed by diluted sulphuric acid. An insoluble calcium sulphate is precipitated, and the disengaged citric acid remains in solution. This is carefully concentrated in leaden boilers until a pellicle begins to form, when it is transferred to other vessels to cool and crystallize.

The commercial lemon juices contain free citric acid; free acids other than citric; citrates, salts of organic acids other than citric; salts of inorganic acids; and albuminous, mucilaginous, saccharine, and other indifferent bodies. Spirit is frequently added as a preservative, and mineral acids are not uncommonly employed as adulterants. Verjuice has also been used for the purpose (Allen). See *Limonis Succus*, also *Montserrat lime juice*, *P. J.*, 1883, p. 606, and notes on manufacture, *N. R.*, 1883, 47.

Preparation.—In the U. S. Pharmacopœia, very properly, no process is given for making citric acid, as it is always purchased from the manufacturing chemist. The former British Pharmacopœia gave the following process for preparing it:

“Take of Lemon Juice *four pints* [Imperial measure]; Prepared Chalk *four ounces and a half* [avoirdupois]; Sulphuric Acid *two fluid-ounces and a half*; Distilled Water *a sufficiency*. Heat the Lemon Juice to its boiling point, and add the Chalk by degrees till there is no more effervescence. Collect the deposit on a calico filter, and wash it with hot water till the filtered liquor passes from it colorless. Mix the deposit with a pint [Imp. meas.] of Distilled Water, and gradually add the Sulphuric Acid previously diluted with a pint and a half [Imp. meas.] of Distilled Water. Boil gently for half an hour, keeping the mixture constantly stirred. Separate the acid solution by filtration, wash the insoluble matter with a little Distilled Water, and add the washings to the solution. Concentrate this solution to the density of 1.21, then allow it to cool, and after twenty-four hours decant the liquor from the crystals of sulphate of calcium which will have formed; further concentrate the liquor until a film forms on its surface, and set it aside to cool and crystallize. Purify the crystals, if necessary, by recrystallization.” *Br.* *

On the large scale the juice is placed in a wooden vat, closed at top, and is saturated with whiting (calcium carbonate). Carbonic acid gas is thus evolved, which passes out by an exit pipe, and may be used in the manufacture of sodium bicarbonate, while calcium citrate precipitates. The supernatant liquor, containing much extractive matter, is drawn off, and the calcium citrate is decomposed by diluted sulphuric acid, liberating the citric acid, and precipitating the lime as a sulphate. The mixture of citric acid and calcium sulphate is run off into a wooden filter-back, lined with lead, furnished with a perforated false bottom, and

lined throughout with stout twilled flannel. The solution of citric acid passes off through a pipe leading from the bottom of the back to suitable reservoirs.

The sulphate is washed until it becomes tasteless, and the washings are run off into the same reservoirs. The filtered acid solution is then concentrated by evaporation in wooden vessels lined with lead, through which steam is made to pass by means of coiled lead pipes. As citric acid is liable to decomposition if subjected to a very high temperature, the use of the vacuum pan is highly advantageous in concentrating the solution. When the liquor is sufficiently concentrated, it is transferred to cylindrical sheet-lead vessels, placed in a warm situation, to crystallize. The crystals at first obtained are colored. In order to purify them, they are redissolved in a small quantity of water, with the assistance of heat, and the solution is digested with purified animal charcoal, filtered, evaporated, and the crystals, after having been washed and drained, are dried on wooden trays lined with sheet-lead, in a room heated by steam.

The calcium citrate of the above process should be decomposed without any delay; for, if kept, it will undergo fermentation, with the effect of destroying the citric acid. According to Personne, the products of this fermentation are acetic and butyric acids, carbon dioxide and hydrogen being evolved. It is desirable to have a slight excess of sulphuric acid, as this rather favors than otherwise the crystallization of the citric acid. It is found necessary, also, to add occasionally a small proportion of sulphuric acid to the citric acid liquor, during the progress of its concentration. According to J. Carter Bell (*N. R.*, 1880, p. 274), the concentrated juice contains from sixty-four to ninety-six ounces of citric acid to the imperial gallon. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of having undergone the acetous fermentation.

Citric acid by fermentation of carbohydrates is claimed by German patent No. 72,957 of 1893, and species of citromyces (*Citromyces pfefferienus* and *C. glaber*) are especially mentioned as bringing about this fermentation. This patent was supplemented by a German patent 91,891 of 1897, based upon the discovery that the same result may be obtained by means of *Mucor pyroformis*. The latter fungus is found on putrefying fruit, especially on pears and apples; its spore carriers grow only in a moist atmosphere and form long white filaments, terminated by brownish-black heads. It can be readily obtained in pure culture by sowing the spores in a suitable medium, such as sugar solutions, beer wort, steamed rice, starch paste, etc., the ordinary room temperature being favorable for its growth. The solution becomes acid from the formation of citric acid. (*J. Soc. Chem. Ind.*, June 30, 1897; see also *P. J.*, 1893, 182; 1894, 893; 1902, 551.)

Ohley (*Ph. Era*, 1901, 706) has devised a process which consists in diluting fresh concentrated lemon juice with twice its volume of water, filtering after standing over night to remove albumen, then adding a calculated quantity of calcium chloride, followed by solution of sodium hydroxide, gradually added, until the solution is exactly neutral, when, upon stirring, a magma of calcium citrate is quickly deposited. From this the sodium chloride formed is readily removed by hot water, and the calcium citrate is then decomposed by the calculated quantity of sulphuric acid. The main advantages of the new process are: convenience, a yield approximating to theoretical figures, and decidedly superior purity of product.

Properties.—"Colorless, translucent, right-rhombic prisms; odorless; having an agreeable, purely acid taste; efflorescent in warm air, and deliquescent when exposed to moist air." *U. S.* Its sp. gr. is 1.6. When heated, it dissolves in its water of crystallization, and at a higher temperature undergoes decomposition, becoming yellow or brown, and forming a very sour syrupy liquid, which is uncrystallizable. By destructive distillation it gives rise at first to water and *aconitic acid*, $C_8H_8O_6$, and on further heating it is decomposed into carbon dioxide, acetone, and *itaconic* and *citraconic acids*, both of the formula $C_5H_6O_4$. "When heated to about $75^\circ C.$ ($167^\circ F.$), the Acid begins to lose its water of crystallization; at about $135^\circ C.$ ($275^\circ F.$) it becomes anhydrous, and melts between 152° and $153^\circ C.$ (305.6° and $307.4^\circ F.$). When slowly ignited, it is gradually decomposed without emitting an odor resembling burning sugar (difference from *tartaric acid*), and is finally consumed without leaving more than 0.05 percent. of residue." *U. S.*

Citric acid is "soluble in 0.54 part of water, and in 1.55 parts of alcohol at $25^\circ C.$ ($77^\circ F.$); in about 0.4 part of boiling water and in 1.43 parts of boiling alcohol; also soluble in 18 parts of ether." *U. S.* "Soluble in three-fourths of its weight of cold or in half its weight of boiling water, somewhat less soluble in alcohol (90 per cent.), and soluble to a slight extent in ether. The aqueous solution made by dissolving 35 grains of the Acid in 1 ounce (or 1 gramme in $12\frac{1}{2}$ cubic centimetres) of water resembles, in acidity, an average specimen of Lemon Juice." *Br.* It is nearly insoluble in chloroform, benzene and petroleum benzin. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition. It is incompatible with alkaline solutions, whether pure or carbonated, converting them into citrates; also with the earthy and metallic carbonates, most acetates, the alkaline sulphides, and soaps. It is characterized by its taste, by the shape of its crystals, and by forming an insoluble salt with lime water when heated, and a deliquescent one with potassium hydroxide. If sulphuric acid be present the acid will be hygroscopic, and the precipitate by lead acetate will

not be entirely soluble in nitric acid, the insoluble portion being lead sulphate. "An aqueous solution of Citric Acid reddens blue litmus paper." On adding 1 Cc. of an aqueous solution of the Acid (1 in 10) to 50 Cc. of calcium hydroxide T.S. (or sufficient of the latter to render the mixture alkaline) the liquid remains clear. Upon boiling this for about one minute, it becomes opaque through the precipitation of calcium citrate, which redissolves on cooling. If 1 Gm. of the powdered Acid be dissolved in 5 Cc. of a cold solution of potassium acetate (1 in 3), the liquid should remain clear, even after the addition of an equal volume of alcohol (absence of *tartaric* or *oxalic acid*.)" *U. S.* (See Spiller, *J. Chem. Soc.*, x. 110.)

Sometimes crystals of tartaric acid are substituted for or mixed with the citric, or the two acids may be mixed in powder, a fraud which is detected by adding a solution of potassium acetate to that of the suspected acids, when, if tartaric acid be present, a crystalline precipitate of potassium bitartrate will be formed. Pusch's method of determining the presence of tartaric acid in citric acid is as follows: 1 Gm. of powdered citric acid is added to 10 Gm. of strong, pure, colorless, sulphuric acid in a dry test tube, and the tube is then immersed in boiling water for an hour. The citric acid dissolves with frothing and evolution of gas, and a lemon-colored liquid is formed, which undergoes no change within half an hour if the sample be pure; but if as much as one-half per cent. of tartaric acid be present, the color is brownish and reddish-brown an hour afterward. (*A. Pharm.*, xxii. 316.) Another delicate method of detecting tartaric acid is to digest the suspected acid with ferric hydroxide in a test tube, afterwards to raise the heat slowly to the boiling point, and, having allowed the excess of hydroxide to subside, to decant the clear liquid, and evaporate it to a syrupy consistence. If the acid be pure, the liquid remains limpid, and of a fine red color; if contaminated with tartaric acid, even to the extent of only one per cent., it becomes cloudy, and deposits tartrate. Another test is potassium permanganate, of which an alkaline solution is without action on citric acid, while under the influence of tartaric acid the manganese peroxide is deposited.

"On mixing 5 Cc. of an aqueous solution of the Acid (1 in 10) with a quantity of ammonia water insufficient to neutralize it completely, and adding to this liquid 1 Cc. of ammonium oxalate T.S., it should remain clear (absence of calcium). The aqueous solution (1 in 10), mixed with a few drops of hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see Part III, Test No. 121), nor, upon the subsequent addition of ammonia water in slight excess, to the solution, should the liquid acquire more than a faint tint (limit of iron). If to 10 Cc. of the aqueous solution of the Acid (1 in 100) a few drops of hydrochloric acid be added, followed by 1 Cc. of barium chloride T.S., no turbidity should re-

sult within five minutes (limit of sulphuric acid). If 5 Gm. of Citric Acid be dissolved in sufficient water to measure 100 Cc., then 34.75 Cc. of this solution should require not less than 24.87 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 4 percent. of pure Citric Acid), phenolphthalein T.S. being used as indicator." U. S. "Each gramme dissolved in water should require for neutralization 14.3 cubic centimetres of the volumetric solution of sodium hydroxide. It should yield no characteristic reaction with the tests for copper or iron, and only very slight reactions with those for calcium or sulphates. Its solutions should not contain any metallic particles. 10 grammes dissolved in 20 cubic centimetres of water, neutralized with solution of ammonia, and sufficient of a saturated aqueous solution of hydrogen sulphide added to produce 100 cubic centimetres of liquid, no darkening of color should result after 5 minutes (absence of lead). One drop of solution of ferrous sulphate, then a few drops of solution of hydrogen peroxide, and finally an excess of solution of potassium hydroxide, added to an aqueous solution of the Acid, no purple or even light violet coloration should result (absence of tartaric acid). Or 1 gramme placed in a test-tube with 5 cubic centimetres of solution of ammonium molybdate, 2 or 3 drops of solution of hydrogen peroxide being added, should not afford a bluish coloration after the tube has been shaken and placed in boiling water for ten minutes (absence of tartaric acid; but the presence of any metallic particles gives rise to a similar coloration). On incineration with free access of air, it should not yield more than 0.05 per cent. of ash." Br.

Lead is often found in the metallic state in citric acid in small quantity, and this arises from small portions being rubbed off in breaking off the crystals from the crystallizing vats. The presence of lead or copper may be detected as above, or by igniting in a porcelain crucible a small quantity of the acid, dissolving the ash in a few drops of nitric acid, diluting largely, and passing hydrogen sulphide through it, a black precipitate indicating the impurity. Some interesting observations in relation to the presence of lead in citric acid and citrates are recorded by Haussmann in *A. J. P.*, 1894, 173.

Composition.—The formula of the anhydrous acid is $C_6H_8O_7H_3$. It is a tribasic acid, and may therefore yield three classes of citrates according as one, two, or three atoms of hydrogen are replaced by metal, the first two classes being acid citrates, and the third class neutral citrates. When crystallized from its solution by cooling, it contains one molecule of water. Crystals of the formula $(C_6H_8O_7)_2 + H_2O$ have also been formed. (Flückiger, *Pharm. Chem.*, 1879, p. 157.) Witter (*Ph. Centralh.*, 1892, 1003) has obtained anhydrous citric acid, in crystals melting at $153^\circ C.$, by heating aqueous solutions of the hydrated acid to $130^\circ C.$ If citric acid be heated until all its water of crystallization

has been driven off, there will be produced aconitic acid ($H_3C_6H_5O_6$), which is found naturally in aconite, larkspur, black hellebore, equisetum, yarrow, and other plants. According to Hentschel, aconitic acid is best obtained by boiling for six hours 100 Gm. of citric acid with 50 Gm. of water mixed with 100 Gm. of pure sulphuric acid in a flask provided with a reverse condenser. Upon cooling the flask a solid cake of aconitic acid is formed, which may be purified by mixing with strong hydrochloric acid, and washing until free from sulphuric acid; colorless, shining crystals are obtained. (*A. Pharm.*, 1887, p. 357.)

Uses.—Citric acid acts as a poison chiefly if not solely by irritating the gastro-intestinal mucous membrane. It is, however, much less irritant than tartaric acid, and, so far as we know, no death has been caused by it. The action of therapeutic doses upon the system is not decided. In scurvy, citric acid is probably of no value. It is eliminated by the kidneys, and, as first stated by Bence Jones, when given in sufficient quantities renders the urine acid. In a free state it is rarely used internally, except as an imperfect substitute for lemon juice. When added in the quantity of six hundred grains to a pint of distilled water, it forms a solution of the average strength of lemon juice. Of this solution, or of lemon juice, twenty grains of potassium bicarbonate saturates three fluidrachms; twenty grains of potassium carbonate, four and a fourth fluidrachms; and twenty grains of ammonium carbonate, five and a half fluidrachms. Half a fluidounce of lemon juice, or of an equivalent solution of citric acid, when saturated, is considered a dose.

An agreeable substitute for lemonade may be made by dissolving from two or four parts of the acid, mixed with sugar and a little oil of lemon, in nine hundred parts of water; or twenty grains of the acid may be dissolved in a pint of water, and sweetened with sugar which has been rubbed on fresh lemon-peel. Citric acid is used as one of the ingredients in the effervescent salts. In the experiments of Strong, one-half to one per cent. of citric acid was found to be so poisonous to the cholera germ as to make impure water to which it was added probably a safe drink. It was further found that a large Philippine lemon, containing 40 Cc. of juice, was the equivalent of 2.74 grammes of citric acid. (*Report Government Laboratories, Philippine Islands*, Sept. 1, 1903.)

Dose, of the acid, from five to thirty grains (0.32 to 2.0 Gm.).

ACIDUM GALLICUM. U. S., Br.

GALLIC ACID

(ăç'î-dŭm găl'lî-cŭm)

"An organic acid [$\text{C}_6\text{H}_2(\text{OH})_3\text{COOH} + \text{H}_2\text{O}$], usually prepared from tannic acid." U. S. "A trihydroxybenzoic acid, $\text{C}_6\text{H}_2(\text{OH})_3\text{COOH}\cdot\text{H}_2\text{O}$. It may be prepared by the action of diluted sulphuric acid on tannic acid." Br.

Trihydroxybenzoic Acid, Dioxysalicylic Acid, Trihydroxybenzoic Acid; Acide gallique, Fr. Cod.; Gal-lussaur, G.; Acido gallico, It.; Acido agallico, Sp.

The former British Pharmacopœia process for making gallic acid is as follows: "Boil one part of coarsely powdered galls with four fluid parts of diluted sulphuric acid for half an hour, then strain through calico while hot; collect the crystals that are deposited on cooling, and purify these with animal charcoal and repeated crystallization." Br.

The process based on sulphuric acid's influence in favoring the change of tannic into gallic acid, requires less time than former processes.

The U. S. 1870 process was founded upon the fact that when galls in infusion, or in the state of moistened powder, are exposed to the air, their tannic acid is gradually converted into gallic acid. The gallic acid, being freely soluble in boiling, but very sparingly in cold water, is extracted from the altered galls by decoction, and is deposited as the water cools. A repetition of the solution and deposition renders the acid more pure; but it cannot be obtained wholly colorless unless by the aid of animal charcoal. There are few processes in which it is more necessary that the animal charcoal should be purified. The presence of the slightest quantity of ferric salt interferes with the bleaching of the acid; and it is even advisable to examine the filtering paper, lest it may contain sufficient of this substance to vitiate the results of the process. The first crop of crystals in the process retains a very large proportion of water; and it will be found convenient to subject them to strong expression between folds of bibulous paper.

The elder Robiquet first suggested that galls contained a principle capable of converting tannic into gallic acid, with the presence of water, and in the absence of atmospheric air. Laroque proved that this principle acts as a ferment, and that the change referred to is the result of a *gallic acid fermentation* in the galls. E. Robiquet showed that galls contain *pectose* and *pectase*, the former of which, according to the experiments of Frémy, is the principle out of which pectin is formed in plants, and the

latter a peculiar ferment which effects the transformation. He believed that in galls the pectase, aided by a proper temperature and the presence of water, changed not only pectose into pectin, but also tannic into gallic acid. Strecker previously advanced the opinion that tannic acid was a combination of gallic acid and sugar, the latter of which is destroyed in the process for procuring gallic acid, which is thus simply set free from the combination. E. Robiquet admitted the occasional transformation of tannic acid into gallic acid and sugar, but did not believe that the sugar pre-existed as such in the tannin. (*J. P. C.*, 3e sér., xxiii. 241.) Wittstein, in endeavoring to obtain gallic acid from *Chinese galls* by forming them into a paste with water, found that but a very small proportion of the acid was generated at the end of six weeks. Thinking that this might have resulted from the want of the ferment in the Chinese galls, he added to these one-eighth of their weight of common galls, and at the end of three weeks obtained an amount of gallic acid nearly equal to one-half the weight of the galls employed. The same result, though more slowly, followed the addition of yeast to the Chinese galls. Wittstein obtained both carbonic acid and alcohol as products of this operation, thus favoring the views of Strecker as to the constitution of tannic acid; and the idea that tannin was a glucoside convertible through exposure of galls to the air, or more rapidly by sulphuric acid, into glucose and gallic acid, was accepted without qualification, until Schiff (*Ber. d. Chem. Ges.*, iv. 231, 967) proved that although crude tannic acid contains glucose, it is possible to separate a large quantity of the glucose without destroying the tannic acid. He proposed that *pure tannic acid* be called *digallic acid*, and that the term *tannin* be applied to natural tannin, i.e., the *glucoside* of digallic or pure tannic acid, for when natural tannin is boiled with diluted mineral acids or subjected to the influence of a nitrogenous ferment, it splits into gallic acid and glucose:

Digallic acid is the first anhydride of gallic acid:

Gallic acid is a *phenol acid*, or combination of these two classes of organic compounds; its formula is $\text{C}_6\text{H}_2(\text{OH})_3\text{COOH}$. It may be termed, therefore, a *trihydroxybenzoic acid*. It is monobasic.

Properties.—Gallic acid is in "white, or pale fawn-colored, silky, interlaced needles, or triclinic prisms; odorless; having an astringent and slightly acidulous taste; permanent in the air. Soluble in 83.7 parts of water, and in 4.14 parts of alcohol at 25° C. (77° F.); in 3 parts of boiling water, and in 1 part of boiling alcohol; also soluble in 40 parts of ether, and in 12 parts of glycerin; very slightly soluble in chloroform, benzene, or petroleum benzin." U. S. It produces a deep bluish-black color with solutions of ferric salts, which disappears when the solution is heated, a result which Mahla

has shown to depend on the conversion of the gallic into *pyrogallie* or *metagallic acid* (pyrogallol) by the loss of carbon dioxide. (*Am. J. Sci.*, Nov., 1859.)

Gallic acid does not precipitate gelatin, or a solution of ferrous sulphate. "When heated at 100° C. (212° F.), the Acid loses its water of crystallization (nearly 9.58 percent.). At about 200° C. (392° F.) it begins to melt, and at a higher temperature it is gradually decomposed. At a low red heat it is consumed without leaving a residue. An aqueous solution of Gallic Acid has an acid reaction upon blue litmus paper." *U. S.* It should leave no residue when burned, and be entirely dissipated when thrown on red-hot iron. On exposure to the air, its solution undergoes spontaneous decomposition; but it is said that by the addition of a drop of oil of cloves it may be kept for a long time without change, the absence of tannin and microscopic fungi being proved. "Gallic Acid neither colors nor precipitates pure ferrous salts, but forms a bluish-black precipitate with ferric salts. On adding to a cold saturated aqueous solution of Gallic Acid some calcium hydroxide T.S., a bluish-white precipitate will form, where the test solution is temporarily in excess, and will disappear on shaking. When the test solution has been added in excess, the precipitate no longer dissolves, and the liquid acquires a tint which is blue by reflected and green by transmitted light, and becomes pink on the addition of a large excess of calcium hydroxide T.S. (distinction from *tannic acid*). An aqueous solution of the Acid should not precipitate alkaloïds, gelatin T.S., albumin T.S., or starch T.S. (difference from and absence of *tannic acid*)."
U. S. "It yields a bluish-black precipitate with *test-solution of ferric chloride*. The crystalline Acid loses 9.5 per cent. of its weight when dried at 212° F. (100° C.). It should yield no characteristic reaction with the tests for sulphates. Its aqueous solution is not precipitated by *solutions of isinglass, albumen, alkaloids, or tartarated antimony* (absence of *tannic acid*). It leaves no residue when burned with free access of air (freedom from mineral matter)." *Br.* By the action of arsenic it is converted almost entirely into tannic acid without the production of arsenous acid. (*Schiff, Chem. News*, xxix. 73.) Young's test, potassium cyanide, gives a reddish color with gallic acid and none with tannic acid. A mixture of ammonium chloride and ammonia produces a red coloration, but no precipitate, in gallic acid solution; while in tannic acid solution it produces a whitish precipitate rapidly turning reddish-brown. (*A. J. P.*, April, 1889.) A test proposed by Flückiger consists in adding to the solution of gallic acid a diluted (1 to 100) solution of pure ferrous sulphate. To the colorless solution a little sodium acetate is to be added, when a deep violet color will appear, due to the formation of ferrous gallate. The *U. S. Pharmacopœia* test is: "If 5 Cc. of a cold saturated aqueous solution of the Acid be treated, in a

watch-glass, with 6 drops of sodium hydroxide T.S., the liquid will gradually acquire a deep green color, which is changed to reddish or brownish-red by acids." *U. S.* Heated to 216° C. (420° F.), gallic acid gives off carbon dioxide, and is changed into *pyrogallie acid*.

Uses.—Gallic acid is astringent, but less powerfully so than tannic acid. As it does not coagulate albumin, it is readily absorbed when ingested, and is rapidly eliminated by the kidneys. Its presence in the urine is, under these circumstances, very readily demonstrated by the addition of a soluble ferric salt. Owing to its being more readily transported by the blood, it is more effective than tannic acid in all cases of hemorrhage (*hæmoptysis, hæmaturia*, etc.) in which the bleeding vessels must be reached through the route of the circulation. But in hemorrhage from the alimentary mucous membrane, or from any other part with which tannic acid can be brought into direct contact, the latter astringent is by far the more effectual. Tannic acid is also much more efficient in anginose or other relaxations in which a decided astringent action is desired and in which a direct application can be made. Gallic acid has been employed with advantage in *pyrosis*, and in the *night-sweats of phthisis or exhaustion*. In *albuminuria*, when there is a very large amount of albumin excreted, gallic acid may be employed with service to diminish the flow, and the drug has even been used in acute *Bright's disease* following *scarlatina*, with asserted great advantage. (*N. R.*, Oct. 1875.) It is said not to constipate the bowels, and may be given in the form of pill or powder. *Ointment of gallic acid*, ten parts of the acid to ninety of benzoïnated lard, was official in the *U. S. Pharmacopœia* of 1880.

Dose, five to fifteen grains (0.32 to 1.0 Gm.)

ACIDUM HYDRIODICUM DILUTUM.

U. S.

DILUTED HYDRIODIC ACID

(ăc'î-dŭm hŷ-dri-ôd'î-cŭm di-lŭ'tŭm)

"A solution of Hydriodic Acid [HI = 126.9], containing not less than 10 percent., by weight, of the absolute Acid, and about 90 percent. of water. It should be kept in amber-colored, glass-stoppered bottles, protected from the light." *U. S.*

Acide hydrolodique diluée, *Fr.*; Verdünnte Jodwasserstoffsäure, *Gr.*

* "Potassium Iodide, one hundred and thirty-five grammes [or 4 ounces av., 333 grains]; Potassium Hypophosphite, ten grammes [or 154 grains]; Tartaric Acid, one hundred and thirty-six and five-tenths grammes [or 4 ounces av., 356 grains]; Distilled Water, Diluted Alcohol, each, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains].

Dissolve the Potassium Salts in two hundred and fifty cubic centimeters [or 8 fluidounces,

217 minims] of Distilled Water with the aid of heat, and the Tartaric Acid in *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol. Having poured the solution of Tartaric Acid into a bottle of about one thousand cubic centimeters capacity, add the solution of the Potassium Salts and shake the mixture briskly. Place the bottle in a bath of ice-water for several hours and, having inserted a pledget of cotton tightly in the throat of a funnel, transfer the contents of the bottle to the funnel. When all the liquid has passed through, wash the bottle and crystalline precipitate with Diluted Alcohol in successive small portions until *one thousand grammes* [or 35 ounces av., 120 grains] of clear solution have been obtained. Evaporate the liquid at a moderate temperature, on a water-bath, until all of the Alcohol has been dissipated, and add sufficient Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains].” U. S.

The official description is as follows: “A clear, colorless liquid, odorless, and having an acid taste. Specific gravity, about 1.106 at 25° C. (77° F.). Miscible, in all proportions, with water or alcohol. On distilling Diluted Hydriodic Acid, water with some weak acid first passes over; at the temperature of 127° C. (260.6° F.), an acid of the strength of 57.5 percent. distills over unchanged. To blue litmus paper it shows a strongly acid reaction. Silver nitrate T.S. produces a yellow, curdy precipitate, insoluble in nitric acid, almost insoluble in ammonia water, but soluble in solutions of sodium thiosulphate and potassium cyanide. If a few drops of ferric chloride T.S. or chlorine water be added to the Acid, diluted with twice its volume of water, iodine will be liberated and impart to the solution a reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color. The Acid should not become colored on keeping. Barium chloride T.S. should not produce a turbidity or precipitate (absence of *sulphuric acid*). The Acid should not be rendered turbid by the addition of potassium sulphate T.S. (absence of *barium*). Diluted Hydriodic Acid, when evaporated to dryness on a bath of boiling water, and then heated to 115° C. (239° F.), should not leave more than 1 percent. of residue. Ten Cc. of the Diluted Acid, without further acidulation, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 5 Cc. of Diluted Hydriodic Acid be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and then evaporated to dryness on a bath of boiling water, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). Into a flask provided with a well fitting stopper, introduce 2.54 Gm. of Diluted Hydriodic Acid, diluted with 50 Cc. of distilled water, followed by 25 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of ferric ammonium sul-

phate T.S., and 3 to 4 Cc. of nitric acid (free from nitrous compounds); then securely stopper the flask, and shake it well. Not more than 5 Cc. of tenth-normal potassium sulphocyanate V.S. should then be required to produce a permanent reddish-brown tint (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 0.5 percent. of absolute Hydriodic Acid).” U. S.

Diluted hydriodic acid was introduced into the U. S. Pharmacopœia 1860; it was dismissed in the revision of 1870, and is again recognized in the present 8th Revision. The old process consisted in passing hydrogen sulphide into a bottle containing iodine and water until the iodine disappeared and the liquid was colorless, it was then filtered to separate the precipitated sulphur and the filtrate heated to drive off the excess of hydrogen sulphide. The reaction is as follows:

Various processes have been proposed for making hydriodic acid. Buchanan used an extemporaneous formula, which consisted in dissolving 330 grains of potassium iodide and 264 of tartaric acid, each in one and a half fluidounces of water, mixing the solutions, filtering to separate the potassium bitartrate formed, and finally adding sufficient distilled water to make the solution measure fifty fluidrachms. Each fluidrachm of this preparation represents five grains of iodine. Dunn's modification of Buchanan's process is as follows: Take of potassium iodide 209½ grains; tartaric acid, in crystals, 190½ grains. Dissolve the iodide in three fluidrachms of distilled water, and the acid in the same quantity, and filter if necessary; mix the solutions, set the mixture in ice-cold water, and allow it to stand for one hour; then filter, and make up the measure to two fluidounces. Each fluidrachm represents 10 grains of iodine. (A. J. P., 1869, 41.) H. Kolbe (J. Pr. Chem., 1879, 172, and A. J. P., June, 1877) adds phosphorus to iodine in a retort filled with carbon dioxide. Heat is applied, and water added; on application of moderate heat, hydriodic acid gas free from iodine is produced. C. Winckler (A. J. P., May, 1880) dissolves iodine in carbon disulphide, adds sufficient water to form a layer on top of the solution of iodine, and passes a stream of hydrogen sulphide through the mixture; when this has acquired a yellow color, the layers are separated, the aqueous hydriodic acid is boiled a few minutes to expel hydrogen sulphide, and it is then chemically pure.

The present U. S. 8th Revision process is based on Buchanan's method, but directs in addition to potassium iodide and tartaric acid, potassium hypophosphite and diluted alcohol. The hypophosphite is added in order to provide a small quantity of hypophosphorous acid which acts as a preservative, while the diluted alcohol aids in the precipitation of the potassium bitartrate because of the insolubility of the latter in alcohol. The ice-water bath is also used to assist

in the separation of the potassium bitartrate.

Uses.—Diluted hydriodic acid is used in the preparation of syrup of hydriodic acid by adding 100 Gm. of the acid to 900 Gm. of syrup and water; as now prepared the acid is reasonably permanent, but it should not be used or dispensed if discolored by the presence of free iodine; it contains ten times the amount of hydriodic acid present in the official syrup of hydriodic acid. Diluted hydriodic acid was introduced into use as a medicine by Andrew Buchanan of Glasgow. The acid official in 1860 contained ten grains of iodine in each fluidrachm, and was therefore twice as strong as Buchanan's solution. There can be little doubt that hydriodic acid is capable of producing the alterative effects of iodine, and it may be given in all cases to which that medicine is applicable. When the solution becomes discolored it may be irritant through the liberated iodine; but this effect may be partially obviated by exhibiting it in any amy-laceous liquid, as barley water.

Dose, ten minims (0.6 Cc.) three times a day, well diluted.

Off. Prep.—Syrupus Acidi Hydriodici, *U. S.*

ACIDUM HYDROBROMICUM DILUTUM.

U. S., Br.

DILUTED HYDROBROMIC ACID

(äc'í-düm hÿ-drô-brô'mj-cüm di-lüt'üm)

"A liquid composed of not less than 10 per cent., by weight, of absolute Hydrobromic Acid [$\text{HBr} = 80.36$], and about 90 percent. of water. It should be kept in amber-colored, glass-stoppered bottles, protected from light." *U. S.*
 "An aqueous solution containing 10 percent. by weight of hydrogen bromide, HBr . It may be obtained by the distillation of potassium bromide with concentrated phosphoric acid." *Br.*

Acidum Bromhydricum Dilutum, Acidum Bromhydricum; Acide Bromhydrique dissous, *Fr. Cod.*; Acide hydrobromique dilué, *Fr.*; Acidum hydrobromicum, *P. G.*; Verdünnte Hydrobromsäure, v. Bromwasserstoffsäure, *G.*

The *U. S.* and *Br.* Pharmacopœias do not give processes for this acid. Both acids are identical in strength. The following process is based upon that of E. R. Squibb: Take of Potassium Bromide and Sulphuric Acid, each, one hundred and fifty parts, Distilled Water, a sufficient quantity. Add the Sulphuric Acid to twenty-five parts of Distilled Water, and cool the mixture. Then dissolve the Potassium Bromide in one hundred and fifty parts of water by the aid of heat, supplying the loss of water by evaporation during the heating. Carefully pour the diluted Sulphuric Acid into the hot solution with constant stirring, and set the mixture aside for twenty-four hours, in order that the Potassium Sulphate may crys-

tallize. Pour off the liquid into a retort, break up the crystalline mass, transfer it to a funnel, and having drained the crystals, drop slowly upon them fifty parts of cold Distilled Water so as to wash out the acid liquid. Add this liquid to that in the retort, and distil nearly to dryness at a moderate heat. If red fumes of bromine are given off during any stage of the distillation, change the receiver as soon as such fumes begin to appear. Finally determine in the distillate the amount of actual Hydrobromic Acid (16.1 Gm. should require 20 Cc. of the volumetric solution of sodium hydroxide), and add to the remaining weighed distillate such an amount of cold Distilled Water as shall cause the finished acid to contain 10 percent. of actual hydrobromic acid. If the bromide used contains bromate, the distillate will probably be tinged with the red color of bromine; should such contamination be produced, the acid may be rendered fit for use by carefully adding solution of sodium sulphite until the acid is deprived of color, and then rectifying it by distillation.

This process for making solution of hydrobromic acid does not differ essentially from that of E. R. Squibb (*A. J. P.*, 1878, p. 116), except in the improvement of the rather smaller proportion of sulphuric acid used, and in the fact of the difference in strength of the two hydrobromic acids, Squibb's being 34 per cent., the above 10 per cent. The advantages possessed by both methods over those frequently used are greater purity of product and more definite strength.

The most convenient process is undoubtedly that of Dewitt C. Wade (*Peninsular Medical Journal*, Feb. 1875), modelled after Buchanan's method of making hydriodic acid, which directs that 120 grains of potassium bromide be dissolved in one fluidounce of water, and 153 grains of tartaric acid be added to the solution; acid potassium tartrate is produced, the greater part of which crystallizes out on standing 12 hours at a low temperature, and a solution of hydrobromic acid is formed, sp. gr. 1.228, containing about 80 grains pure hydrobromic acid to the fluidounce, equivalent to nearly 15 per cent. Fothergill's acid, although based upon Wade's formula, is weaker, the quantity of potassium bromide being 81½ grains and that of tartaric acid 99 grains to the fluidounce, the manipulation being the same; each fluidounce of Fothergill's acid contains about 55 grains of pure hydrobromic acid, or about 10 per cent. Diluted hydrobromic acid made in this way is open to the objection of containing cream of tartar, and probably some undecomposed potassium bromide in solution, and thus is not strictly pure. To lessen this, Charles Rice proposed the addition of a double quantity of alcohol to facilitate the precipitation, recovering the alcohol by distillation subsequently. (*N. R.*, 1877, p. 107.) Other processes have been suggested for the preparation of hydrobromic acid. Edward Goebel (*N. R.*, Sept. 1880) proposed a method

based on Glover's process, which is to decompose 148 grains of barium bromide dissolved in half an ounce of water, with 50.6 grains of sulphuric acid, diluted with two drachms of distilled water; the precipitated barium sulphate is washed with distilled water until the filtrate weighs 810 grains to make the 10 per cent. acid solution. The processes of Balard, Millon, and Loewig are commented upon by John M. Maisch (*Proc. A. Ph. A.*, 1860), who proposed some useful modifications. Markoe (*Ibid.*, 1875, p. 686) recommends an economical process, which, however, must be followed with care, and is better adapted for making the acid on a large scale. He pours a pint of water into a gallon stoneware jar, and then adds one pound or more of phosphorus, distributing it over the bottom; ice is now added until the jar is half full, a gallon glass funnel is inserted in the throat of the jar, and a funnel tube adjusted, so that the end will be a short distance above the surface of the phosphorus; the funnel is about one-third filled with broken ice, and the jar placed in a larger vessel, and broken ice packed between. Three or four pounds of bromine, after being chilled, are slowly added, in order that the fumes of hydrobromic acid and bromine that may arise may be fully condensed by the ice in the funnel, and an accumulation of bromine avoided, which might produce an explosion from too sudden reaction. The excess of phosphorus is removed after all the bromine has been added, the liquid distilled, hydrobromic acid condensed, and the strength adjusted, while to the residue in the retort water may be added to make diluted phosphoric acid. A convenient method for obtaining a small amount of hydrobromic acid gas or solution, was described by L. H. Friedburg, in a communication before the New York Section of the American Chemical Society (May, 1905). Bromine is allowed to trickle into paraffin which is kept in a melted condition by placing the flask containing it in a shallow steam bath. The bromine vapors, which will pass over with the hydrobromic acid, are partly absorbed by a second flask containing paraffin, joined to the first flask and standing with it in the steam bath. (See also Gassman's process, *S. W. P.*, 1893, 107.) Marshall proposed a method which depends on the easy solubility of bromine in hydrobromic acid, the conversion of the bromine into sulphur bromide by the addition of sulphur, and the ready decomposition of sulphur bromide when shaken with water, thus:

(*Y. B. P.*, 1901, 483).

Properties.—Diluted hydrobromic acid is a colorless, transparent liquid, entirely vaporized by heat, inodorous, strongly acid to the taste, sp. gr. about 1.076 (U. S.) at 25° C. (77° F.) and containing 10 per cent. absolute hydrobromic acid. "Miscible, in all proportions, with water or alcohol. On distilling it, water and weak acid first pass over; when the temperature of 126° C. (258.8° F.) is reached, an

acid of 48 percent. remains, which may be distilled unchanged. Diluted Hydrobromic Acid strongly reddens blue litmus paper." U. S. Although of a pungent and irritating odor, and fuming when in contact with the atmosphere when concentrated, in its diluted state it is odorless. On adding chlorine or nitric acid to diluted hydrobromic acid, there is liberated bromine, which is soluble in chloroform or carbon disulphide, imparting to these liquids a yellow color.

Tests.—"Silver nitrate T.S. causes a yellowish-white precipitate, which is insoluble in diluted nitric acid, but slowly soluble in an excess of stronger ammonia water, and readily soluble in solutions of sodium thiosulphate or potassium cyanide. If copper sulphate T.S. be added to the Acid, a deep red color is produced upon the addition of sulphuric acid. The Acid should not become colored on keeping. Barium chloride T.S. should not produce a turbidity or precipitate (absence of *sulphuric acid*). Ten Cc. of the Acid should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). If 10 Cc. of Diluted Hydrobromic Acid be evaporated to dryness, and heated to 110° C. (230° F.), no appreciable residue should remain (limit of *non-volatile impurities*). Ten Cc. of the Diluted Acid without further acidulation, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 10 Cc. of the Acid be shaken with 2 Cc. of chloroform, no color should be imparted to the latter (absence of *free bromine*), and upon subsequently adding chlorine water, which has been previously diluted with an equal volume of water, drop by drop, with shaking, the chloroform should be colored orange, with no trace of violet (absence of *iodine*). Five Cc. of Diluted Hydrobromic Acid should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). If 0.5 Cc. of Diluted Hydrobromic Acid be mixed with 10 Cc. of water, and 8 Cc. of silver nitrate T.S. with 6 Cc. of ammonium carbonate T.S. be added, and if the mixture, after digesting for ten minutes on a bath of boiling water, be cooled and filtered, the filtrate, on supersaturating with nitric acid, should not become more than slightly opalescent (limit of *hydrochloric acid* and *chlorides*). If 10 Gm. of Diluted Hydrobromic Acid be diluted with sufficient distilled water to measure 100 Cc., and if to 8.04 Cc. of this solution, after exact neutralization with diluted ammonia water (litmus T.S. being used as indicator), there be added 3 drops of potassium chromate T.S., then not less than 10 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red tint (each Cc. corresponding to 1 percent. of absolute Hydrobromic Acid)." U. S. "4 grammes should require for neutralization 5 (more exactly 4.98) cubic centimetres of the volumetric solution of sodium hydroxide, or, for complete precipitation, 50 (more exactly

49.8) cubic centimetres of the *volumetric solution of silver nitrate*. It should yield no characteristic reaction with the tests for arsenium, barium, chlorides, phosphates, sulphates, or sulphites. It should yield no residue on evaporation to dryness." *Br.* Concentrated hydrobromic acid has been furnished by manufacturing chemists containing from 20 to 50 per cent. of absolute hydrobromic acid; C. T. Tyrer states that the stronger acids are prone to show discoloration in a few days after being made, but that even the highly colored acids, when diluted to the official strength, become colorless; the concentrated acid attacks glass rapidly and the silica is not thrown out on dilution; he recommends acid of the sp. gr. 1.250 as having the most suitable limit of concentration for pharmaceutical purposes. (*Y. B. P.*, 1896, 296).

The following table by Biel will be found useful in showing from the specific gravities of solutions the percentage of absolute hydrobromic acid.

Biel's Table of Percentage and Specific Gravity of Hydrobromic Acid.

Per cent. HBr.	Specific Gravity at 15°C. (59°F.)	Per cent. HBr.	Specific Gravity at 15°C. (59°F.)
1	1.0082	26	1.219
2	1.0155	27	1.229
3	1.0230	28	1.239
4	1.0305	29	1.249

23	1.190	48	1.490
24	1.200	49	1.496
25	1.209	50	1.513

Uses.—Diluted hydrobromic acid is very nearly identical with potassium bromide in its action, but is too irritant to the stomach to be used freely in *epilepsy* and other serious affections. In an experimental study made by Reichert, of the University of Pennsylvania, it was found to act upon animals precisely as do the bromides in general. It has been especially commended in *trinitus aurium*. Two fluidrachms contain about 12 grains of bromine, equivalent in this to 18 grains of potassium bromide, and may be given at once, well diluted with water or syrup. The addition of a trace of spirit of lemon to the mixture renders the resemblance of this dose to lemonade a very close one.

Dose, from one-half to two fluidrachms (1.8 to 7.5 Cc.).

ACIDUM HYDROCHLORICUM.

U. S., Br.

HYDROCHLORIC ACID

(äc'ŭ-düm hÿ-drq-çhlô'rj-cüm)

"A liquid composed of 31.9 percent., by weight, of absolute Hydrochloric Acid [HCl = 36.18], and 68.1 percent. of water. It should be kept in glass-stoppered bottles." *U. S.* "A liquid containing 31.79 per cent. by weight of hydrogen chloride, HCl , and 68.21 per cent. of water. Obtained by dissolving in water the gas produced by the interaction of sulphuric acid and sodium chloride." *Br.*

Acidum Muriaticum, *Pharm.* 1870; Acidum Hydrochloratum, s. Chlorhydricum; Spirit of Sea Salt, Marine Acid, Muriatic Acid, Chlorhydric Acid; Acide chlorhydrique officinal, *Fr. Cod.*; Acide hydrochlorique, Acide chlorhydrique ou muriatique, *Fr.*; Acidum hydrochloricum, *P. G.*; Salzsäure, Chlorwasserstoffsäure, *G.*; Acido cloridrico concentrato, Acido muratico, *It.*; Acido cloridrico, Acido muriatico, *Sp.*

Preparation.—Hydrochloric acid is obtained mainly by the action of sulphuric acid on sodium chloride or common salt. In England it is produced in enormous quantities during the decomposition of common salt for the purpose of making sodium sulphate, from which soda ash and sodium carbonate are afterwards manufactured in immense quantities. The decomposition of the sea salt is performed in semi-cylindrical vessels, the curved part, next the fire, being made of iron, and the upper or flat surface, of stone. The acid gas is conveyed by a pipe to a double-necked stoneware receiver, half filled with water, and connected with a row of similar receivers, likewise containing water. As carried out on a larger scale, the decomposition of the salt takes place in hemispherical iron pans, 9 feet in diameter, covered by a brick-work dome; upon the mass of salt the requisite quantity of sulphuric acid is allowed to run from a leaden cistern placed above the decomposing pan. Torrents of hydrochloric acid gas are evolved, which collect in the space between the pan and the brick-work dome, whence they pass by a brick-work or earthenware flue into upright towers or condensers. These towers are filled with bricks or coke, down which a small stream of water is allowed to trickle. The gas, passing upward, meets the water and is dissolved by it, and as the acid liquor approaches the bottom, it becomes more and more nearly saturated with gas.

Hydrochloric acid is also made on a commercial scale by the action of steam upon magnesium chloride, which is such an abundant waste product at the rock salt mines of Stassfurt. The process used is that of Weldon as developed by Pechiney of Salindres, in France.

With the increasing development of electrolytic processes for the production of caustic alkali, it has been sought to convert the chlorine set free at the same time into hydrochloric acid. This is done by burning the chlorine direct with the hydrogen set free at the cathode. A pro-

cess of this kind is now being operated at Niagara Falls by the Roberts Chemical Company, who electrolyze potassium chloride and obtain as products potassium hydroxide and hydrochloric acid.

The acid, when required to be pure, is generally prepared by saturating distilled water with the gas in Woulfe's apparatus. A quantity of pure fused sodium chloride is introduced into a retort or flask, placed on a sand bath. The vessel is then furnished with an S-tube, and connected with a series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the extrication of the gas slackens, heat is applied, and gradually increased until the water in the bottles refuses to absorb any more, or until no more gas is found to come over. As soon as the process is completed, boiling water should be added to the contents of the retort or flask, in order to facilitate the removal of the residue. During the progress of the saturation, the water in the several bottles increases in temperature, which lessens its power of absorption. It is, therefore, expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

In the process for hydrochloric acid, theory calls for a little less than 90 parts of liquid sulphuric acid to 100 of common salt. A moderate excess of the former may be useful to insure the complete decomposition of the salt. The reaction for its formation is:

If only half the amount of sulphuric acid be used, the reaction is:

In the first of these reactions, as only one molecule of salt is taken, it is obvious that there is not enough sodium furnished to neutralize the sulphuric acid completely and make the normal sulphate, Na_2SO_4 , so the result is the acid sulphate, HNaSO_4 . On the other hand, in the second reaction, the two molecules of salt furnish just the sodium necessary to neutralize the one molecule of sulphuric acid and make the neutral sulphate, Na_2SO_4 .

As hydrochloric acid, prepared in the ordinary mode, often contains arsenic, so as to obscure its indications when employed in testing for that poison, it is of interest to the practical toxicologist to know that it may be obtained free from that impurity by distilling sodium or potassium chloride with oxalic acid in equivalent proportions.

The following method of freeing hydrochloric acid from arsenic trioxide is recommended by Engel as easy and entirely efficacious. It is founded on the fact that arsenic trioxide is reduced to arsenic by hypophosphorous acid. Into a liter (about 2 pints) of arsenical hydrochloric

acid introduce 4 to 5 grammes (about 60 or 70 grains) of potassium hypophosphite, dissolved in a little water. At the end of an hour or two, the liquid becomes yellow and then brown; and a precipitate soon forms, more or less copious according to the amount of impurity. After the liquid becomes clear, which usually happens in 45 minutes, decant the hydrochloric acid and distil it. The acid thus obtained is entirely free from arsenic. This process should be conducted in a place where the direct rays of the sun may fall on the vessels; or, where this is impossible, the vessels should be subjected, by means of a water bath, from 4 to 6 hours, to a heat little short of the boiling point of the acid. (*J. P. C.*, 1873, p. 10.) Traces of arsenic may also be removed by adding solution of stannous chloride, and after the precipitate of impure arsenic has settled, the clear liquid is redistilled. (Bettendorf, *Zeit. An. Chem.* [2], 5, p. 492.)

Properties of the Pure Acid.—Hydrochloric acid, when pure, is a "colorless, fuming liquid, of a pungent odor, and an intensely acid taste; the fumes and odor disappear on diluting the Acid with two volumes of water. Specific gravity: about 1.158 at 25° C. (77° F.). Miscible, in all proportions, with water or alcohol. On distilling it, at first a stronger acid passes over, until, at 110° C. (230° F.), a liquid containing 20.13 percent. of the absolute acid remains (specific gravity, about 1.098 at 25° C.), which distils unchanged, leaving no residue." *U. S.* Exposed to the air it emits white fumes, owing to the escape of the acid gas and its union with the moisture of the atmosphere. When concentrated, it blackens organic substances, as does sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1.21. The U. S. acid has the specific gravity of 1.158 at 25° C. (77° F.), which is practically equivalent to the figure given in the British Pharmacopœia, which is 1.160 at 15.5° C. (60° F.). When exposed to heat, it continues to give off hydrochloric acid gas, with the appearance of ebullition, until its sp. gr. falls to 1.094, when it properly boils, and may be distilled unchanged, or entirely volatilized.

Hydrochloric acid is characterized by forming, on the addition of silver nitrate, a white precipitate (silver chloride), insoluble in nitric acid, but readily soluble in ammonia. It is incompatible with alkalies, with metallic oxides and their carbonates, and with potassium sulphide, potassium tartrate, tartar emetic, iron and potassium tartrates, silver nitrate, and solution of lead subacetate.

It is very often desirable to know, in chemical and pharmaceutical operations, the quantity of absolute acid contained in samples of acid of different densities. (See table page 36.)

This acid, when pure, will evaporate without residue in a platinum spoon. On heating it with manganese dioxide an abundance of chlorine gas is given off. If sulphuric acid

¹ Add if the temperature is above, subtract if below, 25° C.

² Corresponding with difference in specific gravity of 0.0001.

NOTE.—To find the per cent. of chlorine, multiply the per cent. of HCl by 0.9724.

To find the weight in grammes of HCl in 100 Cc., multiply the specific gravity by the per cent. of HCl.

To find the volume per cent. of official Hydrochloric Acid, multiply the "normality" by 9.823. For the volume per cent. of official Diluted Hydrochloric Acid, multiply the "normality" by 34.60.

be present, a solution of barium chloride will cause a precipitate of barium sulphate in the acid, previously diluted with distilled water. Iron may be detected by saturating the diluted acid with sodium carbonate, and then adding potassium ferrocyanide, which will strike a blue color if that metal be present, or by the simple

addition of potassium sulphocyanate, when a blood-red coloration is produced. The absence of arsenic may be inferred if it does not tarnish bright copper foil when boiled with it. "If 10 Cc. of the Acid be evaporated from a platinum or porcelain dish, and dried at 110° C. (230° F.), no appreciable residue should remain

(limit of *non-volatile impurities*). If to 5 Cc. of Hydrochloric Acid, diluted with an equal volume of water, 1 Cc. of chloroform be added, and if chlorine water which has been diluted with an equal volume of water be then cautiously added, a drop at a time, with constant agitation, the chloroform should remain free from any yellow, orange, or violet color (absence of *bromine* or *iodine*). If 1 Cc. of the Acid be diluted with 5 Cc. of water, and if 1 Cc. of potassium iodide T.S. with 1 Cc. of chloroform be added, and the mixture agitated, the chloroform should be free from any violet coloration (absence of *free chlorine* or *bromine*). Five Cc. of diluted Hydrochloric Acid (1 in 10), should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). If 1 Cc. of the Acid be diluted with 5 Cc. of water, and a few drops of barium chloride T.S., be added, no precipitate or turbidity should appear within one hour (absence of *sulphuric acid* or *sulphates*), nor should the addition to this mixture of a few drops of tenth-normal iodine V.S. produce any turbidity (absence of *sulphurous acid*). Hydrochloric Acid when diluted with distilled water (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Introduce into a stoppered weighing-bottle 3 Cc. of Hydrochloric Acid and weigh accurately. Dilute the Acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 3.618, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Hydrochloric Acid in the latter." *U. S.* "Each gramme, diluted with water, should require for neutralization 8.7 cubic centimetres of the *volumetric solution of sodium hydroxide*, and 0.1 gramme should require, for complete precipitation, 8.7 cubic centimetres of the *volumetric solution of silver nitrate*. It leaves no residue on evaporation, and when diluted with water should yield no characteristic reaction with the tests for arsenium, lead, copper, iron, aluminium, bromides, iodides, sulphates, or sulphites. Diluted with much water and solution of *potassium iodide* added, no blue color is produced on the addition of *mucilage of starch* (absence of free chlorine)." *Br.* Ammonia in excess, if it produces no precipitate, shows the absence of iron.

If a small portion of the diluted acid be treated with test zinc, the evolved gas should not blacken paper wet with silver nitrate test solution (arsenous or sulphurous acid). Free chlorine or nitric acid may be discovered by its having the power to dissolve gold leaf. Any minute portion of the leaf which may be dissolved is detected by adding a solution of stannous chloride, which will give rise to a purplish tint. The free chlorine is derived from the reaction of nitric or nitrous acid on a small

portion of the hydrochloric acid, which is thus deprived of its hydrogen. Hence it is that, when free chlorine is present, nitrous acid or some other oxide of nitrogen is also present as an impurity. The nitric and nitrous acids are derived from nitrates found as impurities in the common salt and from nitrous acid in the commercial sulphuric acid employed in the preparation of the hydrochloric acid.

Hydrochloric Acid of Commerce. Muriatic Acid.—This acid has the general properties of the pure aqueous acid. It has a yellowish color owing to the presence of ferric chloride, or of a minute proportion of organic matter, such as cork, wood, etc. It usually contains sulphuric acid, and sometimes free chlorine and nitrous acid. But the most injurious impurity, to those who consume it in the arts, is sulphurous acid. Savory analyzed three samples of commercial hydrochloric acid, each having a sp. gr. of between 1.16 and 1.17, and found them to contain from 7 to nearly 11 per cent. of sulphurous acid. To detect this acid, Girardin has proposed a very delicate test, namely, stannous chloride. The mode of using the test is to take about half an ounce of the acid to be tested, and to add to it two or three drachms of stannous chloride. The mixture having been stirred two or three times, as much of distilled water as of stannous salt is to be added. If sulphurous acid be present, the hydrochloric acid becomes turbid and yellow immediately upon the addition of stannous chloride; and upon the subsequent addition of the water a slight evolution of hydrogen sulphide takes place, perceptible to the smell, and the liquid assumes a brownish hue, depositing a powder of the same color. The manner in which the test acts is as follows: By a transfer of chlorine, stannic chloride and metallic tin are produced, the latter of which, by reacting with the sulphurous acid, gives rise to a precipitate of stannic and stannous sulphides. In case the sulphurous acid forms but one-half of one per cent. of the commercial acid, the precipitate may not be perceptible. Under these circumstances, a solution of copper sulphate must be added to the liquid previously warmed, when a brown precipitate of copper sulphide will be immediately formed (Heintz). Or, if a weak solution of iodine be decolorized by the hydrochloric acid, sulphurous or arsenous acid may be suspected. Lambert has proposed the following, which he considers as a more delicate test for sulphurous acid. Saturate the suspected hydrochloric acid with potassium carbonate, and add successively a little weak solution of starch, one or two drops of solution of potassium iodate, and sulphuric acid, drop by drop. Sulphurous acid, if present, will be set free with iodic acid, and these, by reacting on each other, will develop iodine, which will cause a blue color with the starch. Or the addition of pure zinc will liberate nascent hydrogen, which will cause the evolution of hydrogen sulphide gas, detected with lead acetate paper, and this test is preferable.

An impurity very frequently present in the commercial acid, as shown by Dupasquier, is arsenic. (See U. S. P. tests above.) The immediate source of this impurity is the sulphuric acid used to prepare the hydrochloric acid. The sulphuric acid derives the arsenic from the sulphur used in its manufacture, and this last from pyrites containing a little of the poisonous metal. The arsenic, when present, is in the form of a trichloride, and, from its volatility in this state of combination, is transferred to the hydrochloric acid, distilled from the commercial acid. This impurity is separated by diluting the acid with an equal volume of water, and passing through it hydrogen sulphide, which thus throws down the arsenic as a trisulphide. According to Wittstein, hydrochloric acid is freed from arsenic by mercury, according to Reinsch, by copper, and in either case it may be deprived of metallic impregnation by careful distillation. (*A. J. P.*, 1851, p. 408.) M. Auguste Houzeau asserts that to deprive commercial arseniferous hydrochloric acid of arsenic it is sufficient simply to boil it, in a flat bottomed vessel, to two-thirds of its original volume, all the arsenic escaping in the form of the trichloride. (*J. P. C.*, 4e sér., i. 97.) Bettendorf separates arsenous and arsenic acids from hydrochloric acid, sufficiently concentrated, by precipitating with stannous chloride, and then distilling the acid; when it is so treated, it is perfectly free from arsenic. (*A. J. P.*, 1870, p. 219.) When leaden vessels are used in preparing hydrochloric acid, it is likely to contain lead chloride, which falls as a white precipitate on neutralizing the acid. The nature of the precipitate is verified by dissolving it in nitric acid and adding potassium iodide, when the yellow lead iodide will separate (Hainault). Scheffer proved the presence of lead in a sample used for making solution of ferric chloride (*A. J. P.*, Nov. 1875). Another instance was noted by F. Reppert (*A. J. P.*, Dec. 1875). This impurity, being fixed, may be separated by distilling the acid. A small proportion of thallium has been detected in commercial hydrochloric acid by Wm. Crookes, being derived from sulphuric acid, in the manufacture of which pyrites was employed. Selenium has been found in French hydrochloric acid, causing the acid to have a bad odor.

Properties of Hydrochloric Acid Gas.—Hydrochloric acid gas is colorless and elastic, possessing a very pungent odor, and the property of irritating the organs of respiration. It destroys life and extinguishes flame. It reddens litmus powerfully, and has the other properties of a strong acid. Its sp. gr. is 1.278 (Gay-Lussac and Biot). Subjected to a pressure of 40 atmospheres, at the temperature of 10° C. (50° F.), it is condensed into a transparent liquid, to which alone the name of *liquid hydrochloric acid* properly belongs. Water absorbs this gas with the greatest avidity.

It consists of one volume of chlorine and one of hydrogen, united without condensation.

Toxicological Properties.—Hydrochloric acid, when swallowed, is highly irritating and corrosive, but less so than sulphuric or nitric acid. It produces hicough, violent efforts to vomit, and agonizing pain in the stomach. There is much thirst, with great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid has been recently swallowed, white vapors of a pungent odor will be emitted from the mouth. The best antidote is magnesia, but soap or sufficiently diluted alkaline solutions are almost equally efficient. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on general principles.

Uses.—Hydrochloric acid is tonic, refrigerant and antiseptic. It is exhibited, largely diluted with water, in *low fevers*, *phthisis*, some forms of *syphilis*, and to counteract *phosphatic deposits* in the urine. It is especially valuable in *gastro-intestinal indigestion* when there is no tendency to diarrhoea, and may often be added with advantage to liquid preparations of calumba, gentian, and cinchona. It is also frequently given in *dyspepsia* along with pepsin, to aid its solvent powers. (See *Acidum Hydrochloricum Dilutum*.) In concentrated form, it is decidedly caustic, but weaker than nitric acid, and is often used to destroy small dermal growths.

Dose, five to ten minims (0.3 to 0.6 Cc.), well diluted.

ACIDUM HYDROCHLORICUM DILUTUM. U. S., Br.

DILUTED HYDROCHLORIC ACID

(ăc'î-dûm hÿ-drô-clô'rî-cûm di-lû'tûm)

"Diluted Hydrochloric Acid should contain 10 percent., by weight, of absolute Hydrochloric Acid [$\text{HCl} = 36.18$], and 90 percent. of water. It should be kept in glass-stoppered bottles." *U. S.* "100 parts by weight should contain 10.58 parts of hydrogen chloride, HCl ." *Br.*

Acidum Muriaticum Dilutum, *Pharm.*, 1870; Diluted Muriatic Acid; Acide chlorhydrique diluée, *Fr.*; Acidum hydrochloricum dilutum, *P. G.*; Verdünnte Salzsäure, *G.*; Acido cloridrico diluito, *It.*

* "Hydrochloric Acid, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, two hundred and nineteen grammes [or 7 ounces av., 317 grains], to make three hundred and nineteen grammes [or 11 ounces av., 110 grains]. Mix them." *U. S.*

"Hydrochloric Acid, 6 fl. ounces (more exactly, 6.035, Imperial measure) or 3063 grains, or 301.8 cubic centimetres or 350.1 grammes; Distilled Water, a sufficient quantity. Introduce the Hydrochloric Acid into a glass flask, the capacity of which to a mark on the neck is *one pint* (Imp. meas.) or one thousand cubic centimetres; add Distilled Water until the mixture, at 60° F. (15.5° C.), after it has been shaken, measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The official description is as follows: "Specific gravity: about 1.049 at 25° C. (77° F.). It does not fume in the air and is without odor, but otherwise it should conform to the reactions and tests given under *Acidum Hydrochloricum*. If to 3.62 Gm. of Diluted Hydrochloric Acid there be added about 20 Cc. of water, it should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Hydrochloric Acid), methyl-orange T.S. being used as indicator." *U. S.*

The British diluted acid is slightly stronger than the U. S. preparation. "Sp. gr. 1.052, containing 10.58 per cent. by weight of absolute acid. Each gramme should require for neutralization 2.9 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should be free from the impurities mentioned under '*Acidum Hydrochloricum*.'" *Br.*

For medicinal properties and uses, see *Acidum Hydrochloricum*.

Dose, from ten to thirty minims (0.6 to 1.8 Cc.), to be taken in water.

The United States Pharmacopœia (8th Rev.) gives only an extemporaneous process for this acid (see below); that of the U. S. P. 1890, which may be used on a larger scale, is as follows: "Potassium Ferrocyanide, in coarse powder, *twenty grammes* [or 308 grains]; Sulphuric Acid, *eight cubic centimeters* [or 1 fluidrachm, 11 minims]; Water, *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims]; Distilled Water, *a sufficient quantity*. Place the Potassium Ferrocyanide in a tubulated retort, and add to it *forty cubic centimeters* [or 1 fluidounce, 3 fluidrachms] of water. Connect the neck of the retort (which is to be directed upward), by means of a bent tube, with a well-cooled condenser, the delivery tube of which terminates in a receiver surrounded with ice-cold water, and containing *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims] of Distilled Water. All the joints of the apparatus, except the neck of the receiver, having been made air-tight by means of well-fitting corks, pour into the retort, through the tubulure, the Sulphuric Acid, previously diluted with *twenty-five cubic centimeters* [or 6 fluidrachms, 45 minims] of Water. Gently mix the contents of the retort, and then heat it, in a sand-bath, so as to keep the liquid in brisk ebullition, until about one-half of its volume has passed over into the receiver. Detach the receiver, and assay a small portion of the contents by the method given below. Then add to the remainder so much Distilled Water as may be required to bring the product to the strength of *two per cent.*, by weight, of absolute Hydrocyanic Acid." *U. S.* 1890.

Diluted Hydrocyanic Acid may be prepared, extemporaneously, by the U. S. P. (8th Rev.) process: "Silver Cyanide, *six grammes* [or 92.5 grains]; Diluted Hydrochloric Acid, *fifteen and fifty-four hundredths cubic centimeters* [or 4 fluidrachms, 12 minims]; Distilled Water, *forty-four and one-tenth cubic centimeters* [or 1 fluidounce, 3 fluidrachms, 56 minims]. Mix the Diluted Hydrochloric Acid with the Distilled Water, add the Silver Cyanide, and shake the whole together in a glass-stoppered bottle. When the precipitate has subsided, pour off the clear liquid." *U. S.*

The British Pharmacopœia does not give a detailed process for preparing this acid. It describes it as "a colorless liquid with a peculiar odor. Specific gravity 0.997. It only slightly reddens *litmus*. It yields, when neutralized, the reactions characteristic of cyanides." *Br.* It will be seen that both official acids recognize the same standard (2 per cent. of hydrogen cyanide).

When potassium ferrocyanide is decomposed by sulphuric acid, the residue in the retort is potassium sulphate, mixed with an insoluble compound of iron cyanide and potassium cyanide (*Everitt's Salt*). The reaction is expressed by the following equation:

Half of the cyanogen present in the potas-

sium ferrocyanide goes to form the hydrocyanic acid, while the other half remains in the white residue. Everitt's salt, so named from its discoverer, is a yellowish-white powder. Like potassium ferrocyanide, it is a double salt (iron and potassium cyanide), but of different molecular ratio. As it appears in practice, it is apt to be greenish, owing probably to the presence of a little Prussian blue.

In the U. S. process for obtaining hydrocyanic acid extemporaneously, the reacting materials are single molecules respectively of silver cyanide and hydrochloric acid. These, by double decomposition, generate hydrocyanic acid, which dissolves in the water, and silver chloride, which subsides, and from which the acid is poured off when clear. (See *Argenti Cyanidum*.) The extemporaneous process is useful to country practitioners, because the acid will not keep indefinitely. A portion of hydrocyanic acid, if purchased by a practitioner, may spoil on his hands before he has occasion to use it; but if he supply himself with silver cyanide, he may readily at any moment prepare a small portion of the acid, by following the directions of the formula. It is doubtful, however, whether all of the silver cyanide will be decomposed, except under much more careful treatment than the process is likely to receive.

The change which was made in the process of the Pharmacopœia of 1880, in the substitution of diluted alcohol for the distilled water formerly used as the solvent for the hydrocyanic acid, was in accordance with the views of Gault and others, who asserted that greater stability was thus secured. It was not of sufficient value to be retained in the U. S. P. 1890, and the use of diluted alcohol was abandoned. (F. T. Drake, *Proc. A. Ph. A.*, 1891, p. 147.)

Another process for obtaining medicinal hydrocyanic acid, proposed by Clark, and adopted by Laming, is by the reaction of tartaric acid on potassium cyanide in solution. Laming's formula has been modified as follows: Potassium cyanide, pure, 65 parts; tartaric acid, 150 parts; alcohol, 675 parts; water, sufficient to make 1538 parts. Mix the potassium cyanide and tartaric acid with 500 parts of water in a well-stoppered bottle, or dissolve each separately in 250 parts of water, and mix the solutions; then add the alcohol and sufficient water to make 1538 parts. After the acid potassium tartrate has subsided as a heavy crystalline powder, the clear supernatant liquid is decanted.

The yield of official acid is 1350 parts, but the generated cream of tartar weighs 188 parts, thus making the 1538 parts as above directed. The solution contains mere traces of the acid tartrate. (*A. J. P.*, 1883, p. 559.)

Great care must be observed in using this process to procure pure potassium cyanide, the commercial article usually being adulterated.

Investigations have shown that potassium ferrocyanide is decomposable not only by the weakest acids but also by numerous non-acid organic substances, hydrocyanic acid being liber-

ated; thus the diluted mineral acids (containing even less than 0.1 per cent.), formic, acetic, butyric, lactic, tartaric, benzoic acids, even carbon dioxide and hydrogen sulphide, phenols, peptones, casein, etc., will decompose potassium ferrocyanide more or less quickly at temperatures below 100° C., liberating a portion of the hydrocyanic acid. (*A. J. P.*, 1893, p. 283).

The processes thus far given are intended to furnish a *diluted* hydrocyanic acid for medicinal purposes. The methods of obtaining the *anhydrous* acid are different. Vauquelin's process for the anhydrous acid is to pass a current of hydrogen sulphide gas over mercuric cyanide contained in a glass tube, connected with a receiver kept cold by a freezing mixture of ice and salt. The first third only of the tube is filled with cyanide; the remaining two-thirds being occupied, half with lead carbonate, and half with calcium chloride; the carbonate being intended to retain the excess of hydrogen sulphide gas, while the chloride is intended to separate water.

The process of Wöhler for the anhydrous acid is the following: The potassium cyanide selected is a black cyanide, formed by fusing together, in a covered crucible, 8 parts of dry ferrocyanide, 3 of ignited cream of tartar, and 1 of charcoal in fine powder. The cyanide, while still warm, is exhausted by 6 parts of water; and the clear solution, placed in a retort, is decomposed by cold diluted sulphuric acid, gradually added. The hydrocyanic acid is condensed first in a U-tube containing calcium chloride and surrounded with ice cold water, and afterwards in a small bottle, connected with the U-tube by a narrow tube, and immersed up to the neck in a mixture of ice and salt. After the acid has been condensed and dehydrated in the U-tube, the cold water surrounding it is withdrawn by a siphon, and replaced by water at a temperature between 29.4° and 32.2° C. (85° and 90° F.), whereby the anhydrous acid is made to distil over into the small bottle. Wade and Panting prepare pure hydrocyanic acid by dropping a mixture of equal parts of sulphuric acid and water upon *pure* potassium cyanide and condensing the vapors. (*M. R.*, 1898, 339.)

Berthelot has made hydrocyanic acid synthetically. He first prepared, by a direct synthesis of its elements, *acetylene* (C_2H_2). He then mixed this gas with pure nitrogen, passed a series of electric discharges from a Ruhmkorff coil through the mixture, and, when the odor of prussic acid was perceptible, agitated with a solution of potassium hydroxide to get the fixed cyanide. It has also been made by heating chloroform with ammonia and potassium hydroxide solution. (Hofmann.)

Properties of the Diluted Acid.—Diluted hydrocyanic acid, of the proper medicinal strength, is officially described as "a colorless liquid, of a characteristic odor resembling that of bitter almonds. On account of its poisonous character it should be tasted with great caution.

It is completely volatilized by heat. Diluted Hydrocyanic Acid shows an acid reaction with blue litmus paper. If to 1 Cc. of the Acid, rendered alkaline by potassium hydroxide T.S., a few drops of ferrous sulphate T.S. be added and the mixture boiled and then acidulated with hydrochloric acid, a blue precipitate will be formed." *U. S.* It imparts a slight and evanescent red color to litmus. If it reddens litmus strongly and permanently, some acid impurity is present. It loses strength rapidly in open vessels. It is not reddened by potassium and mercury iodocyanide. The non-action of this test shows the absence of contaminating acids, which, if present, would react upon the iodocyanide and produce mercuric iodide. The red color produced when ammonium picrate is added to a solution of an alkaline cyanide and heated has been proposed as a test for prussic acid. (*Guyot, N. R.*, May, 1877.) It is liable to undergo decomposition if exposed to the light, but it may be kept for a longer time in a bottle covered with black paint or black paper. From experiments carefully conducted by Bussy and Buignet, it appears that, when the alteration in the acid under the influence of light has begun, it will afterwards go on very rapidly in the dark; and that after exposure for a certain time to the light, though no alteration may be apparent, an influence has nevertheless been exerted which disposes to change, and promotes decomposition even in the absence of light. Hence the necessity of immediately enclosing the acid in bottles from which the light is excluded. (*J. P. C.*, 1863, p. 475.) Experience has shown that it is best preserved in cork-stoppered bottles of amber glass; when glass and rubber stoppers were used, decomposition frequently took place rapidly.¹ Its most usual impurities

are sulphuric and hydrochloric acids, the former of which may be detected by barium chloride, which will produce a precipitate of barium sulphate, and the latter by precipitating with silver nitrate, when so much of the precipitate as may be silver chloride will be insoluble in boiling nitric acid, while the silver cyanide is readily soluble.

It is now generally acknowledged that mineral acids prevent the deterioration of the diluted prussic acid. But the presence of a mineral acid is not necessary for its preservation, for Christison has known the medicinal acid from potassium ferrocyanide to keep perfectly well, although barium nitrate did not produce the slightest cloudiness. Nevertheless it has been frequently shown that much of the acid kept in the drug stores is below the official strength. Various remedies have been proposed. (*P. J.*, July, 1871; Feb. 1, 1874; Sept., 1874.) One of these is to reduce the strength to one-tenth per cent., this weak solution being said not to undergo change. In our experience a one per cent. acid retained its properties through very severe tests of exposure. John Williams has found in a series of experiments that the addition of 20 per cent. of glycerin has a very pronounced influence in preventing deterioration of the acid. (*P. J.*, Sept., 1874; Sept., 1875.)

Formerly the medicinal acid was of different strengths, as ordered by the different pharmaceutical authorities, but happily the U. S. and Br. Pharmacopœias conform in this important point. At one time its strength was indicated by its specific gravity, which is lower in proportion as it is stronger; but this inaccurate method is not now relied on, and, though the British Pharmacopœia gives the sp. gr. of its diluted acid at 0.997, both Pharmacopœias give quantitative tests as indices of the strength.

Assay.—U.S.P. 1890. "To ascertain the percentage strength, mix in a flask (of the capacity of about 100 Cc.) 0.27 Gm. of Hydrocyanic Acid (obtained by distillation as above directed) with sufficient water and magnesia to make an opaque mixture of about 10 Cc. Add to this 2 or 3 drops of potassium chromate test-solution, and then, from a burette, silver nitrate decinormal volumetric solution, until a red tint is produced which does not again disappear by shaking. Each Cc. of silver nitrate volumetric solution used indicates 1 per cent. of absolute Hydrocyanic Acid. After ascertaining the strength of the distillate, dilute it with Distilled Water so as to bring it to the strength of 2 per cent. of absolute acid. Lastly, test the finished product again, when 1.35 Gm. of it should require, for complete precipitation,

¹ Anhydrous hydrocyanic acid sometimes undergoes an apparently spontaneous molecular change by which it is converted into a black solid body, which was supposed to be *paracyanogen* or one of its compounds. This change takes place more slowly in aqueous solutions of the acid, which are converted into a black liquid, and it is only in a state of extreme dilution, when, for example, water contains not more than one per cent. of the acid, that it is altogether prevented. It sometimes takes place in the official diluted acid; and Procter exhibited a bottle, which had been most carefully closed, and kept excluded from the light, in which, nevertheless, the acid had become as black as ink. The cause of this phenomenon remained long unknown; but in 1862 M. E. Millon satisfied himself, by experiment, that the real agency was the presence of ammonia, which may sometimes operate even through the air. It has also been asserted that the cause of the decomposition is the presence of a microscopic plant. (*J. P. C.*, 1862, p. 48.) The preservative influence of a little sulphuric acid in the diluted hydrocyanic acid would be explained by its neutralization of ammonia; and it is not impossible that the greater resistance offered to the change by the preparation made by the original process, in which sulphuric acid is used, than by the others, may be owing to the influence of this acid, either passing over with its vapor, or acting on the acid vapor before it leaves the retort. An important practical inference from all this is the necessity of providing, as far as possible, that ammonia should in no manner have access to the acid, during or after its preparation. The effect of ammonia in inducing changes in diluted hydrocyanic acid is denied by Pettit. (*A. J. P.*, 1873.) Rimmington asserts that hydrocyanic acid acts upon the alkali of some varieties of glass. Siebold, who has confirmed this,

declares that the addition of hydrochloric acid is useless as a preservative, except when prussic acid is kept in bottles which yield the alkali. (*P. J.*, Sept. 1874.) Lescol and Rigaut (*O. R. A. S.*, Aug. 4, 1879) state that pure hydrocyanic acid can be preserved for a long time; but the presence of potassium cyanide causes decomposition even in the absence of water.

10 Cc. of silver nitrate decinormal volumetric solution." U. S. 1890. This method of assay is based upon Pappenheim's process for the determination of hydrocyanic acid in bitter almond water, as described by Veilhaber in *A. Pharm.*, 1878, p. 408. In the absence of free mineral acid silver nitrate precipitates the whole of the cyanogen as white silver cyanide before any of the red silver chromate is formed; the test is vitiated by the presence of hydrochloric acid or chlorides and has been replaced in the U. S. P. 8th revision by the following test, which resembles in principle that of the British Pharmacopœia: "If 5 Gm. of Diluted Hydrocyanic Acid be diluted with distilled water to measure 50 Cc., then 26.9 Cc. (26.84 Cc.) of this solution, after the addition of 5 Cc. of ammonia water and 3 drops of potassium iodide T.S., should require for the production of a slight permanent precipitate, the addition of not less than 10 Cc. of tenth-normal silver nitrate V.S." U. S. The Br. Pharmacopœia directs that "each gramme of Diluted Hydrocyanic Acid, rendered alkaline by the addition of solution of sodium hydroxide, and maintained faintly alkaline throughout the operation, should require the addition of 3.7 cubic centimetres of the volumetric solution of silver nitrate before a permanent precipitate begins to form." Br.

Tests.—The Br. Pharm. requires that "5 cubic centimetres evaporated in a platinum dish should leave no residue. It should yield only the slightest reactions with the tests for sulphates or chlorides." Br. To explain the volumetric test it should be noticed that silver cyanide, though itself insoluble, is rendered soluble by combining with sodium cyanide, in the proportion of one molecule of each. When, therefore, the diluted hydrocyanic acid is converted, by the addition of sodium hydroxide, into sodium cyanide, no permanent precipitate will begin to appear, upon the addition of silver nitrate, until more than sufficient silver cyanide is produced to form the soluble compound referred to, which happens when one-half of the sodium cyanide has been converted into silver cyanide. An acid of the strength indicated by either of these methods contains two per cent. of anhydrous acid. The former test of entire solubility in boiling nitric acid, applied to the precipitate obtained by silver nitrate, was intended to verify its nature; for, if the hydrocyanic acid contained hydrochloric acid, part of this precipitate would be silver chloride, not soluble in the boiling acid. *Scheele's medicinal hydrocyanic acid* contains about 5 per cent. of anhydrous acid, and therefore two minims of it are equal to five of the U. S. acid. The use of *Scheele's* acid should be discouraged as unnecessary and very dangerous. In view of the deterioration of hydrocyanic acid upon keeping through loss by volatilization, the following approximate practical test is recommended by E. R. Squibb: If one drop of diluted hydrocyanic acid be added to 15 Cc. of distilled water in one vessel, and

one drop of silver nitrate test solution (U. S. P.) be added to 7 Cc. of distilled water in a test tube, and the first solution be dropped into the second from a pipette, and the contents be closely observed for a few seconds between the drops, a distinct opalescence should be observed before the fourth drop is added, and should become very marked as the fourth and fifth drops are added.

Fordos and Gélis have proposed, as a test of the strength of the compounds containing cyanogen, an alcoholic solution of iodine of known strength; as, for example, three grains to the fluidounce. The test solution is added, drop by drop, to the cyanogen compound, until a permanent yellowish tinge is produced. The iodine unites with the cyanogen, and with the substance in combination with the cyanogen, in the ratio of their several equivalents; and hence the cyanogen present is easily calculated from the proportion of iodine expended in uniting with it. This test is commended for its accuracy by James Robertson of Manchester, Eng. (See *A. J. P.*, 1853, p. 551.) Link and Moeckel (*Zeit. An. Chem.*, 1878, p. 455) made a series of experiments, and showed that the most delicate test for hydrocyanic acid was that of iron sulphocyanate. (*A. J. P.*, 1879, p. 86.)

Properties of the Anhydrous Acid.—Hydrocyanic acid, perfectly free from water, is a colorless, transparent, inflammable liquid, of extreme volatility, boiling at 27° C. (80° F.), and congelating at -15° C. (5° F.). Its sp. gr. as a liquid is 0.6969, at the temperature of 18° C. (64° F.); and as a vapor 0.9423. Its taste is at first cooling, then burning, with an after-taste in the throat like that of bitter almonds; but, from its extremely poisonous nature, it must be tasted with the utmost caution. Its odor is so strong as to produce immediate headache and giddiness, and its vapor so deleterious that the smallest portion of it cannot be inhaled without the greatest danger. Both water and alcohol dissolve it readily. It is much more prone to undergo decomposition than the diluted acid. In the course of a few hours it sometimes begins to assume a reddish-brown color, which becomes gradually deeper, till at length the acid is converted into a black liquid, which exhales a strong odor of ammonia. It is a very weak acid in its chemical relations, and reddens litmus but slightly. It does not form solid compounds with metallic oxides, but cyanides of metals, the elements of water being eliminated. According to Sobero, hydrocyanic acid is generated, in sensible quantities, by the action of weak nitric acid on the volatile oils and resins. Wöhler affirmed in 1828 that picric acid when treated with baryta water yields it; and Julius Post and H. Hübner have found that nitrobenzene and dinitrobenzene do also when treated, the former with fusing potassium hydroxide, the latter with boiling diluted solution of potassium hydroxide. Though a product of art, it exists in some plants, and is

generated by reaction between the constituents of many vegetable products upon contact with water. These principles are usually amygdalin and emulsin, but according to Peckholt the root of *Manihot utilisima* (Pohl) copiously generates hydrocyanic acid with water, although he was unable in 15 analyses to find amygdalin in it. (*A. J. P.*, Oct., 1872.) (See *Amygdala Amara*.)

Composition.—Hydrocyanic acid consists of one atom each of cyanogen and hydrogen; or, in volumes, of one volume of cyanogen and one of hydrogen without condensation, its formula being HCN or HCy. Cyanogen, (CN)₂, is a colorless gas, of a strong and penetrating odor, inflammable, and burning with a beautiful bluish-purple flame. Its sp. gr. is 1.8157. It was discovered in 1815 by Gay-Lussac, who viewed it as a compound radical which when combined with hydrogen becomes hydrocyanic acid. Hydrocyanic acid, in a diluted state, was discovered in 1780 by Scheele, who correctly stated its elements to be carbon, nitrogen, and hydrogen; but the peculiar way in which they are combined was first pointed out by Gay-Lussac, by whom also the anhydrous acid was first obtained.

Uses.—Diluted hydrocyanic acid has been much used in respiratory diseases and to quiet cough, but its action is so fugacious that it has really very little medicinal value except as a local remedy in sick stomach of nervous origin and in *gastrodynia*. Externally, it may be of great service in *pruritus*.

It should be administered with the greatest caution, on account of its minute dose, and its variable strength as usually found. The proper plan, therefore, is to begin with a small dose, two drops, for example, and gradually to increase the quantity until some obvious impression is produced. On account of the rapidity and fugaciousness of its action, it should be given at intervals of not more than two hours; indeed, it is very improbable that the largest therapeutic dose of the substance exerts any influence whatever upon the system one hour after its ingestion. If giddiness, weight at the top of the head, sense of tightness at the stomach, or faintness come on, its use should be discontinued. In all cases in which a fresh portion of medicine is used, the dose should be lowered to the minimum quantity, lest the new sample should prove stronger than that previously employed. When resorted to as a lotion, from thirty minims to a fluidrachm may be dissolved in a fluidounce of distilled water.

Dose, one to four minims (0.06 to 0.25 Cc.).

Toxicology.—Hydrocyanic acid is one of the most deadly poisons known, and frequently exceedingly rapid in its action. According to Christison, a grain and a half of the anhydrous acid is capable of producing death in the human subject. One or two drops of the pure acid are sufficient to kill a vigorous dog in a few seconds. Sometimes death occurs almost instan-

taneously. Usually, however, three stages of the poisoning are manifest: a first, very brief one, of difficult respiration, slow cardiac action, and disturbed nervous action; a second, violent convulsive stage, with dilated pupils, vomiting, often loud cries, unconsciousness, etc.; and a third, closing period, of asphyxia, collapse, and paralysis, sometimes interrupted by convulsions. When smaller doses are ingested, the symptoms come on more slowly, but are similar to those just described, and when paralysis is developed it affects both motility and sensation. A peculiar bloated look of the deeply suffused face and neck, with frothing at the mouth, occurring along with the symptoms previously described, is almost pathognomonic of the poisoning. The odor of hydrocyanic acid is sometimes very strong, and should always be searched for about the mouth. It is very important as an aid in the diagnosis, but is certainly not always present. Death is usually the result of asphyxia, produced by a direct paralyzing action of the poison upon the respiratory centres. The poison appears also to have a direct paralyzing action upon the heart, and sometimes to produce fatal syncope. The post mortem appearances are glistening and staring expression of the eyes, gorged state of the venous system with fluid, dark, or bluish-black blood. The lungs are sometimes natural, at other times turgid with blood. The blood may be of a uniform arterial or venous hue, according as the death has been rapid or slow. Death, if it should occur, usually takes place in from one to forty minutes. One case has, however, been reported in which it was delayed one hour and a quarter. When recovery is brought about, the symptoms in most cases abate very rapidly. T. & H. Smith of Edinburgh, recommended as an antidote for the medicinal acid a mixture of ferric salts, swallowed after the administration of magnesia as follows: From one to two drachms of magnesia, made into a smooth cream with water, are to be first swallowed, and then 16 minims of solution of perchloride of iron (*Br.*) and 12½ grains of ferrous sulphate dissolved in water. These quantities are calculated for 100 minims of medicinal hydrocyanic acid. Should more than this be supposed to have been taken, the ferruginous ingredients must be increased in proportion, but not the magnesia. (*P. J.*, 1865, 276.) Cobaltic nitrate has been found, in some cases when injected freely into the lower animals, to lessen the symptoms of cyanic poisoning, but is itself so poisonous that its use in the human subject is hardly justifiable. (*Ph. Z. R.*, 33, 518.) Attempts have been made to neutralize hydrocyanic acid in the system by converting it into a haloid compound through the subcutaneous injection of solutions of bromized sodium bromide and iodized sodium iodide (see Goldfarb, *Wirkungen d. Jodycans, Dissert.*, Dorpat, 1892), but this mixture has been condemned by Kobert, and in itself does not seem to us at all advisable. Kobert and Krohl (*Arbeiten d. Pharm. Inst. z. Dorpat*,

1891, vii.; *Ph. Centralh.*, 1891) have found that in the lower animals good results may be achieved in the poisoning by the conversion in the system of the prussic acid into oxamide by means of peroxide of hydrogen. The oxamide is itself somewhat poisonous, and after its production it is essential to give large draughts of water to wash it out of the system. It is affirmed that in various mining and extracting establishments, and in certain chemical works, where the cyanides are used in enormous quantities, Kobert's method is practically employed, and Merck furnishes what is known as an "antidote-box," containing the necessary apparatus and the supply of hydrogen peroxide. When the cyanide has been taken into the system the peroxide must be introduced by means of a stomach tube into the stomach itself, and the latter should then be washed out. Before or immediately after the administration by the mouth the salts should be given hypodermically. In cases of poisoning by inhalation the antidote should be used subcutaneously. The poison's action is, however, so rapid that there is rarely time for any antidote to be of value. Atropine, which has been suggested as physiologically antagonistic to hydrocyanic acid, has no antidotal value.

Tests.—After suspected death from poison, it is sometimes necessary to ascertain whether the event was caused by the acid. At a period long after death it would be needless to search for so volatile a poison; but it has been recognized three weeks after death, in a case reported by Brame, in which about six drachms of acid, containing between 8 and 9 per cent. of anhydrous acid, had been swallowed. If the autopsy be not too long deferred, the odor of the acid is generally perceptible when the cadaver is opened. The odor after nitrobenzene poisoning resembles very closely that of the acid, but it is affirmed that the diagnosis can be made by leaving the opened body exposed; the odor of the acid will disappear, and that of the nitrobenzene remain. One of the best tests is that proposed by Liebig in 1847, consisting in the change of the hydrocyanic acid into ammonium sulphocyanate, which salt is then tested with a ferric salt. Two drops of the acid, so diluted as not to afford the least blue tint with the salts of iron, upon being mixed with a drop of ammonium sulphhydrate (yellow from dissolved sulphur), and heated upon a watch glass until the mixture is colorless, yield a solution of ammonium sulphocyanate which becomes of a deep blood-red color upon the addition of ferric sulphate, in consequence of the formation of iron sulphocyanate. (*Chem. Gaz.*, April 1, 1847; from *An. Ch. Ph.*) This test is praised by A. S. Taylor, who found it to act characteristically on two grains of diluted hydrocyanic acid, containing only 1-3930th of a grain of anhydrous acid. To render the test this delicate, Taylor deems it necessary to evaporate the liquid gently to dryness, after the addition of the ammonium

sulphhydrate, in order to bring the sulphocyanate to the solid state before adding the ferric salt, a fractional part of a drop of which will commonly suffice to produce the characteristic color. The red color is instantly discharged by solution of corrosive sublimate or mercuric nitrate, and is thus distinguished from that which might possibly be produced under similar circumstances by acetic acid. Should the acid be mixed with organic matters, Taylor proposes a modification of Liebig's test, as follows: Place it in a watch glass, and invert over it another, holding in the centre a drop of ammonium sulphhydrate. In from half a minute to ten minutes, without heat, the ammonium sulphhydrate will be converted into ammonium sulphocyanate, and upon removing the upper glass, and evaporating its contents to dryness, the ferric salt will produce the blood-red color. Even more delicate than the sulphocyanate reaction is the formation of Prussian blue as follows: A drop or two of ferrous sulphate solution is added to the suspected liquid together with one drop of solution of ferric chloride, and the mixture shaken and heated gently; on acidifying now with diluted hydrochloric acid, blue flocks of precipitated Prussian blue separate, or with very diluted solutions a blue or bluish-green color is obtained. O. Henry and E. Humbert have proposed, as a test for hydrocyanic acid, first to convert it into silver cyanide by distilling the suspected matters into a diluted solution of silver nitrate, and then to decompose the cyanide by iodine, so as to form cyanogen iodide. The dried cyanide is added to half its estimated weight of pure iodine, contained in a test tube. Upon the application of a gentle heat, cyanogen iodide is formed, and characteristic crystals of it are deposited on the cool surface of the tube. (*J. P. C.*, 1857, p. 173.) Wormley (*Micro-Chemistry of Poisons*, 2d ed., 186) considers the silver nitrate test as the most delicate of all when the hydrocyanic acid vapor is distilled from a mixture and received in a drop of silver nitrate solution placed in a watch glass above it.

An extremely sensitive test of hydrocyanic acid in the state of vapor has been offered by Schönbein. It consists of white filtering paper imbued with the resin of guaiacum by dipping it in a solution of 3 parts of the resin in 150 of alcohol, and then drying. At the moment of use it is to be moistened with a solution of copper sulphate containing 1 part in 500 parts of water. If now brought into contact with hydrocyanic acid, whether dissolved in water or diffused in the air in the form of vapor, it instantly becomes blue. According to Schönbein, it will change color in air containing only a forty-millionth part of hydrocyanic acid. The test cannot, however, be relied on, since a similar reaction is yielded by numerous other substances, such as nitrous, nitric, and hydrochloric acids, chlorine, bromine, iodine, ammonia, diluted sulphuric acid, chromium trioxide, potassium dichromate, etc. The

paper should be exposed to a current of air drawn through the suspected liquid, and, if indications be yielded, distillation practised to get the volatile acid in a state of sufficient purity to be submitted to the sulphocyanate test. This, as performed by Almén and Strieve, consists in adding ammonium sulphide, to form the sulphocyanate, converting this into the non-volatile potassium sulphocyanate by the addition of a few drops of solution of potassium hydroxide, then evaporating nearly or quite to dryness, adding a few drops of water acidulated with hydrochloric acid, and finally adding a drop or two of solution of ferric chloride, when the blood-red color of the sulphocyanate will be developed. (*B. M. S. J.*, July, 1873.) Another test, which was proposed by Schönbein, and which was found by Büchner to be exceedingly delicate, is dependent upon the power prussic acid has of preventing the catalytic action of the red blood corpuscles. Normally, when these are brought into contact with hydrogen peroxide, the latter is decomposed and oxygen liberated; if prussic acid be present, no oxygen is set free, but the mixture becomes of a deep brown color. In this way Büchner recognized 5 milligrammes of the anhydrous acid in 600 grammes of blood and water. This test is not applicable to old blood.

A very delicate test proposed for hydrocyanic acid is as follows: About one-half centigramme (one-twelfth grain) of ammonio-ferrous sulphate (or other pure ferrous salt) and the same quantity of uranic nitrate are dissolved in 50 Cc. of water, and 1 Cc. of this test liquid is placed in a porcelain dish. On now adding a drop of a liquid containing the smallest quantity of prussic acid, a gray purple color or a distinct purple precipitate is produced. (*M. Carey Lea, Am. J. Sci.* [3], ix. 121-123.)

Dose, of diluted hydrocyanic acid, one ℥ to four minims (0.06 to 0.25 Cc.).

ACIDUM HYPOPHOSPHOROSUM. U. S.

HYPOPHOSPHOROUS ACID

(*ăc'î-dûm hÿ-pô-phôs-phô-rô'sûm*)

"A liquid composed of 30 percent., by weight, of absolute Hypophosphorous Acid [$\text{PO.H}_2(\text{O})\text{H} = 65.53$], and 70 percent. of water. It should be kept in glass-stoppered bottles." *U. S.*

Acide hypophosphoreux, *Fr.*; Unterphosphorigesäure, *G.*

This acid was introduced into the U. S. P. (8th Rev.) to have a permanent concentrated solution of hypophosphorous acid which could be conveniently reduced in strength by adding water, as in making the official diluted acid.

Properties.—It is officially described as "a colorless liquid, without odor, and having an acid taste. Specific gravity: about 1.130 at 25° C. (77° F.). Miscible, in all proportions,

with water. Hypophosphorous Acid, even when largely diluted with water, has an acid reaction upon blue litmus paper. When heated in a porcelain dish, water evaporates, and the acid becomes more concentrated. On further heating between 130° and 140° C. (266° and 284° F.), it decomposes, forming hydrogen phosphide, which ignites, and phosphorous acid; the latter between 160° and 170° C. (320° and 338° F.) decomposes into hydrogen phosphide and phosphoric acid; the pasty residue finally reddens, ignites, and the last portions of unoxidized phosphorus burn out at a higher temperature. The addition of silver nitrate T.S. to Hypophosphorous Acid, diluted with an equal volume of water, produces a black precipitate of metallic silver; the addition of mercuric chloride T.S., a white precipitate of mercurous chloride. When the Acid is gently heated with copper sulphate T.S., a yellow precipitate forms, which rapidly assumes a reddish-brown color. If some of the Acid be neutralized with ammonia water, a clear liquid should result, and a portion of this liquid should not become turbid upon the addition of potassium sulphate T.S. (absence of *barium*); nor should more than a slight turbidity be produced in another portion by barium chloride T.S. (limit of *phosphoric, phosphorous, sulphuric, oxalic, and tartaric acids*). Ten Cc. of the Acid should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Neither platinic chloride T.S. nor sodium cobaltic nitrite T.S. should produce more than a slight yellow turbidity in the diluted Acid (limit of *potassium*). If 2 Cc. of Hypophosphorous Acid be measured into a beaker containing 3 Cc. of nitric acid, which has been previously diluted with about 10 Cc. of water, and the whole evaporated to dryness on a bath of boiling water, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). If 10 Gm. of Hypophosphorous Acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require 30 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Hypophosphorous Acid), methyl-orange T.S. being used as indicator." *U. S.*

Uses.—This acid is not used for medicinal purposes; in pharmacy it is employed in making the diluted acid.

Off. Prep.—Acidum Hypophosphorosum Dilutum, *U. S.*

ACIDUM HYPOPHOSPHOROSUM DILUTUM. U. S.

DILUTED HYPOPHOSPHOROUS ACID

(*ăc'î-dûm hÿ-pô-phôs-phô-rô'sûm dî-lû'tûm*)

"A liquid composed of 10 percent., by weight, of absolute Hypophosphorous Acid [$\text{PO.H}_2(\text{O})\text{H} = 65.53$], and 90 percent. of water." *U. S.*

Acide Hypophosphoreux dilué, *Fr.*; Verdünnte Unterphosphorigesäure, *G.*

* "Hypophosphorous Acid, two hundred grammes [or 7 ounces av., 24 grains]; Distilled Water, four hundred grammes [or 14 ounces av., 48 grains], to make six hundred grammes [or 21 ounces av., 72 grains]. Mix them. Keep the product in well-stoppered bottles." *U. S.*

This acid was introduced into the *U. S. Pharmacopœia* of 1890, and retained in the 8th Revision mainly because of its value as an addition, as a reducing agent, to pharmaceutical preparations containing iodides, which are liable to decomposition through exposure to light and air. Diluted hypophosphorous acid has proved to be the most satisfactory preservative to these easily decomposed salts. It may be added directly, or, as in the case of diluted hydriodic acid, a hypophosphite can be employed, and the salt decomposed by an acid during the manipulation. It may be made on a large scale, however, by boiling phosphorus with milk of lime and subsequently decomposing the calcium hypophosphite with a strong acid, oxalic acid being frequently used for this purpose. The following process of Procter's (*A. J. P.*, 1858, p. 121) is based on this principle. Take of calcium hypophosphite 480 grains, crystallized oxalic acid 350 grains, distilled water 9 fluidounces. Dissolve the hypophosphite in 6 fluidounces of the water, and the acid in the remainder with the aid of heat; mix the solutions, pour the mixture on a white paper filter, and when the liquid has passed add distilled water carefully till it measures 10 fluidounces; evaporate this to 8½ fluidounces. Charles T. Tyrer prefers to make this acid by decomposing barium hypophosphite carefully with diluted sulphuric acid. Hypophosphorous acid can be made to contain 30 per cent. of absolute acid; such an acid has the sp. gr. of 1.137 at 15.6° C. (60° F.), and does not deposit on long standing. (See preceding article.)

Properties.—Diluted hypophosphorous acid is a colorless, odorless liquid, having a sour taste and acid reaction: "Specific gravity: about 1.042 at 25° C. (77° F.). It should respond to the reactions and tests given under *Acidum Hypophosphorosum*. If 10 Gm. of Diluted Hypophosphorous Acid be diluted with distilled water to measure 100 Cc., then 65.5 Cc. of this solution should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 per cent. of absolute Hypophosphorous Acid), methyl-orange T.S. being used as indicator." *U. S.*

Uses.—This acid is believed by many clinicians to have tonic properties, but is very rarely, if ever, used for medicinal purposes except in combinations with strychnine, quinine, or iron, which are thought by many practitioners to be especially valuable in *nervous debility*.

Dose, from five to twenty minims (0.3 to 1.3 Cc.).

ACIDUM LACTICUM. *U. S.*, *Br.*

LACTIC ACID

(lăc'î-dûm lăc'î-l-cûm)

"A liquid organic acid, composed of not less than 75 percent., by weight, of absolute Lactic Acid [$\text{CH}_3\text{CHOH.COOH} = 89.37$], and about 25 percent. of water." *U. S.* "A liquid containing 75 per cent. of hydrogen lactate, $\text{C}_3\text{H}_5\text{CHOH.COOH}$, with 25 per cent. of water. It may be produced by the fermentation of lactose." *Br.*

Oxypropionic Acid, Ethidenelactic Acid, Isolactic Acid; Acide lactique, *Fr. Cod.*; Acidum lacticum, *P. G.*; Milchsäure, *G.*; Acido lactico, *Sp.*

Lactic acid was discovered in 1780 by Scheele. It exists in sour milk, and has been found in a number of the secretions, including the healthy gastric juice, in which its presence has been incontestably proved by Bernard and Barreswil. Lactic acid has been proved to be a product of the viscous or lactic fermentation of rice water, or of the juices of the beet, turnip, and carrot. Indeed, it is formed whenever sugar in solution, of whatever kind, is placed in contact with an alkaline or earthy carbonate in presence of a special ferment, as, for example, the casein of milk, or cheese which contains it. Pasteur demonstrated that the lactic acid fermentation, like the vinous, is caused by a peculiar microscopic plant or mycoderma. It is attended with the production not only of lactic acid, but of other substances also, and among them a peculiar gum-like substance in abundance, which, first noticed by Kirchof, has been isolated in a pure state by Brüning. Though similar to arabin and dextrin, with the formula $\text{C}_6\text{H}_{10}\text{O}_5$, it is not exactly identical with either. The lactic acid of fermentation is one of four isomeric acids possessing the formula $\text{C}_3\text{H}_5\text{O}_3$. The *first* of these is the official lactic acid, and is inactive optically. The *second* is identical chemically with this, but physically different, being dextrorotatory, and is found in the juice of flesh. It is called *paralactic acid*. The *third* or *ethylene lactic acid* is found mixed with the *second* in the so-called "*sarcocollac*" acid extracted from meat. The *fourth* acid has only been obtained synthetically, and is known as *hydracrylic acid*.

Preparation.—Lactic acid may be obtained by the following process, which was recommended by Louradour as the first step in preparing ferrous lactate: Ferment whey by keeping it at a temperature between 21.1° C. (70° F.) and 26.6° C. (80° F.), whereby it becomes charged with a considerable quantity of lactic acid. Evaporate the liquor to one-third of its bulk, decant and filter, and then saturate with milk of lime. This converts the lactic acid into calcium lactate, which remains in solution, and

a precipitate is thrown down, consisting principally of calcium phosphate. The liquor is filtered again, and precipitated by oxalic acid, which throws down the lime as calcium oxalate, and sets free the lactic acid. By a third filtration a solution of lactic acid is obtained, containing lactose (sugar of milk) and certain salts. From these it may be purified by concentrating it to a syrupy consistence and treating it with alcohol, which dissolves the acid, and precipitates the lactose and foreign salts. The solution is filtered, and the lactic acid is obtained pure by distilling off the alcohol. Wackenroder's method is to mix 10 parts of skimmed milk, 2.5 of milk sugar, 2 of chalk, and 20 of water, to digest at about 23.8° C. (75° F.) for a month, or till the chalk is dissolved, then to express, clarify, and evaporate so as to crystallize the calcium lactate, and, after recrystallization, to decompose it with sulphuric or oxalic acid in exact saturating proportions.

Alan A. Claffin thus describes the manufacture of lactic acid as carried out at the present time on a large scale under the patent of Charles E. Avery (*J. Soc. Chem. Ind.*, June 30, 1897). A saccharine solution varying in density from 1.05 to 1.075 is taken. This will contain from 7.5 to 11 per cent. of saccharine matter. It is advantageous to have from 10 to 15 per cent. of this, cane sugar, the rest being grape sugar. The saccharine solution, having been made up and boiled for an hour to insure sterilization, is conveyed into the fermentation tank and cooled to from 55° to 45° C., and then impregnated with nitrogenous matter (such as is extracted from bran by the action of boiling water and diluted acid) in amount equal to about 8 per cent. of the saccharine matter, and the *Bacillus acidi lactici*. In continuous manufacture the ferment solutions are impregnated from a preceding ferment liquor in which a lively fermentation is in progress; 20 per cent. of such impregnating liquor may be added. The impregnation having taken place at 45° C. or over, the temperature is allowed to decrease somewhat as the fermentation proceeds. The glucose is practically all decomposed, and the yield of lactic acid is over 98 per cent. As the fermentation progresses the solution must be neutralized with milk of lime, as the limits of acidity in which lactic acid bacteria are healthy are rigidly confined between 0.02 and 0.5 per cent. If the fermenting solution is overneutralized, the butyric ferment will immediately begin to act, and once active is difficult to control. The lactic fermentation is best completed in from three to six days, and when the fermentation is ended, the liquor must be heated sharply to kill all bacteria and spores and prevent subsequent fermentation. The solution is now filtered and evaporated, when calcium lactate may be crystallized out; or if commercial syrupy acid only is required, the solution may be at once decomposed by sulphuric acid.

Kiliani (*Ber. d. Chem. Ges.*, xv. 136 and 699) has found that lactic acid may be readily pre-

pared by the action of potassium or sodium hydroxide upon either grape sugar or invert sugar (*i.e.*, cane sugar after treatment with diluted acids). He considers invert sugar to be the best material for use in preparing the acid, as it gives a better yield than ordinary glucose, and recommends caustic soda in preference to caustic potash.

His method for the preparation of lactic acid is as follows: 500 grammes of cane sugar are placed with 150 grammes of water and 10 Cc. of the sulphuric acid, in a stoppered flask of 2 liters' capacity and heated for 3 hours to about 50° C. (122° F.). The solution of invert sugar so obtained is colorless, or at most faintly yellow. After cooling there is to be added to it in portions of 50 Cc. at a time 400 Cc. of a caustic soda solution made by dissolving 1 part of caustic soda in 1 part of water. The strong alkali settles at first as a slimy mass on the bottom, and a new portion is only to be added when the mixture has become perfectly homogenous by shaking. The flask should also be cooled with water while the alkali is being added. The mixture nevertheless becomes colored and greatly heated. Finally the mixture is heated to 60° or 70° C. (140° to 158° F.) until a portion heated over a boiling water bath does not separate cuprous oxide from Fehling's solution, but gives it only a slight greenish tinge. Into the cooled mixture the calculated amount of sulphuric acid (made by mixing 3 parts of sulphuric acid with 4 of water) is then run. As soon as the acid liquid has cooled to the temperature of the room, a crystal of Glauber's salt is dropped in and the flask dipped in cold water until a thin crystalline crust forms on the sides, which is removed by a rapid shaking of the flask. Cooling and shaking are continued until a crust no longer forms, when the mixture is allowed to stand at rest for 12 to 24 hours. At the end of this time the contents of the flask appear to consist of a crystalline cake soaked with a reddish liquid. There is then added alcohol of 93 per cent., and the whole is shaken up until on further addition no precipitate separates out. The separated Glauber's salt is freed from the alcoholic solution by a vacuum filter, and can be washed with relatively very little alcohol. The half of the alcoholic solution is neutralized over the water bath with zinc carbonate, filtered boiling hot, and united with the other half. The crystallization begins immediately upon cooling, and is complete after standing 36 hours. The zinc lactate so obtained can be pressed free from mother liquor and crystallized once, when it is perfectly pure. The weight of this first crystallization amounts to from 30 to 40 per cent. of the sugar used. The concentrated mother liquor yields yet another portion of nearly pure, although slightly yellowish, crystals. The zinc lactate may then be treated with hydrogen sulphide to remove the zinc. For a method of making lactic acid from corn meal, see *N. R.*, 1882, p. 235.

George Jacquemin adds the pure lactic ferment, prepared by Pasteur's method, with a quantity of pure sterilized calcium carbonate, to a wort at 45° C. Fermentation is conducted at that temperature, care being taken to exclude dust, to admit filtered air at the bottom of the vessel, and to allow the carbon dioxide to escape. Fermentation is complete in five or six days, and the solution of calcium lactate is freed from nitrogenous matters by the addition of tannic acid. The calcium lactate crystallizes out on evaporation of the filtrate. This may be decomposed with an exact quantity of sulphuric or oxalic acid. (*Chem. News*, 1891, lxiv. 62.) Beckers (*Ap. Ztg.*, 1899, 400) patented a process for making lactic acid from the liquors obtained in the manufacture of "sour kroust" which were formerly wasted. The liquor is neutralized with lime, filtered, evaporated and set aside to crystallize; the calcium lactate is purified, if necessary, by washing or recrystallization and then dissolved in cold water and the solution treated with sufficient sulphuric acid to set free the lactic acid.

Properties.—Lactic acid is "a colorless, syrupy liquid, odorless, of a purely acid taste, and absorbing moisture on exposure to damp air. Specific gravity: about 1.206 at 25° C. (77° F.). Freely miscible with water, alcohol, or ether; insoluble in chloroform, petroleum benzine, or carbon disulphide. Lactic Acid is not vaporized by a heat below 160° C. (320° F.); at a higher temperature it emits inflammable vapors, and is finally dissipated; 5 Gm., after combustion, should not leave more than 0.05 Gm. of fixed residue. Lactic Acid has an acid reaction upon blue litmus paper. On adding some potassium permanganate to a mixture of equal volumes of Lactic and sulphuric acids, and gently heating, the odor of aldehyde will become perceptible." *U. S.*

Exposed to a temperature of 150° C. (302° F.), it is for the most part converted into a new body, which is called concrete lactic acid or *lactide*, an anhydride having the formula $C_6H_4O_4$. It coagulates albumin and dissolves a large quantity of freshly precipitated calcium phosphate, a property which doubtless renders it important in the animal economy. "Ten Cc. of a solution of the Acid in distilled water (1 in 100) should not be rendered opalescent by 1 Cc. of silver nitrate T.S. (limit of *chloride*). Ten Cc. of an aqueous solution (1 in 10) should remain unaffected by the addition of 1 Cc. of barium chloride T.S. (absence of *sulphate*), or by 1 Cc. of copper sulphate T.S. (absence of *sarcocollatic acid*), nor should it respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). On adding a few drops of Lactic Acid to 10 Cc. of hot alkaline cupric tartrate V.S., no red precipitate should be formed (absence of *sugars*). On warming Lactic Acid, the odor of rancid fat should not be noticeable (absence of *butyric* and *other fatty acids*). If a small portion of the Acid be

heated on a water-bath with an excess of zinc carbonate, the mixture dried at 100° C. (212° F.), and then extracted with absolute alcohol, upon evaporation of the latter no sweet residue should remain (absence of *glycerin*). On carefully pouring Lactic Acid upon an equal volume of colorless, concentrated sulphuric acid contained in a clean test-tube, and keeping the temperature at or below 15° C. (59° F.), no dark-colored zone should develop at the line of contact upon standing for fifteen minutes (absence of more than traces of *organic impurities*). If 5 Gm. of Lactic Acid be diluted with water to measure 50 Cc., then 44.7 Cc. of this solution should require for complete neutralization not less than 37.5 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 2 percent. of absolute Lactic Acid), phenolphthalein T.S. being used as indicator." *U. S.* "Warmed with *potassium permanganate* it gives the odor of aldehyde. Each gramme should require for neutralization 8.3 cubic centimetres of the *volumetric solution of sodium hydroxide*. . . . Gently warmed, there should be no rancid odor (absence of fatty acids). No turbidity, either permanent or transient, should be produced when the Acid is added drop by drop to twice its volume of *ether* (absence of gum, sugar, mannite, calcium phosphate). It should give no precipitate with *solution of lead subacetate* (absence of malic and sulphuric acids)." *Br.* At the last revision, *diluted lactic acid* (*Acidum Lacticum Dilutum*, *Br.*, 1885) was dropped from the British Pharmacopœia; the old preparation was of the strength of three fluidounces to the pint (*Imp. meas.*) and had a specific gravity of 1.040. The *U. S. P.* (8th Rev.) and the British Pharmacopœia now recognize the 75 per cent. acid.

Uses.—Lactic acid has been used in *dyspepsia*; for the removal of *phosphatic deposits* in the urine; also used in *tuberculous diarrhœa*, and in the *green diarrhœa of children*. The remedy should be taken at the time of meals, in solution sweetened with sugar, prepared like lemonade. Cantani, of Naples, was induced by theoretical considerations to employ lactic acid in *diabetes*, and reported very remarkable success. (*Ed. M. J.*, 1871, p. 533.) The use of this remedy, however, has not met with the success anticipated.

Hypnotic properties have also been ascribed to lactic acid, but the claim has not been verified. In concentrated form lactic acid is an active caustic; when diluted it is stimulant and germicidal. The 50 to 80 per cent. solution has been used as a caustic antiseptic in *infected wounds*, *ozæna*, *otitis*, *endometritis*, etc.; the 20 per cent. solution has been used for the destruction of false membrane in *diphtheria*; the three per cent. solution has been strongly recommended by Sneguirewa for irrigation in foul *leucorrhœas*.

Dose, twenty to thirty minims (1.3 to 1.8 Cc.).

ACIDUM NITRICUM. U. S., Br.

NITRIC ACID

(äc'î-düm nî'trî-cüm)

"A liquid composed of 68 percent., by weight, of absolute Nitric Acid [HNO_3 or NO_2OH = 62.57], and 32 percent. of water. It should be kept in glass-stoppered bottles." *U. S.* "A liquid containing 70 per cent. by weight of hydrogen nitrate, HNO_3 , and 30 per cent. of water, prepared by the interaction of sulphuric acid and potassium or sodium nitrate." *Br.*

Acidum Nitri, s. Azoticum, Spiritus Nitri Acidus; Spirit of Nitre; Aqua Fortis; Acide azotique officinal, *Fr.* Ood.; Acide nitrique, *Fr.*; Acidum nitricum, *P. G.*; Salpetersaure, *G.*; Acido nitrico concentrato, *It.*; Acido nitrico, *Sp.*; Zaltpeterzuur, *Sterkwater*, *Dutch*; Shedwater, *Suo*.

Nitric oxide is one of the five compounds formed by nitrogen and oxygen. These are, nitrogen monoxide or hyponitrous oxide (laughing gas), N_2O ; nitrogen dioxide, N_2O_2 , or N_2O_4 ; nitrous oxide, N_2O_3 ; nitrogen tetroxide or peroxide, N_2O_4 ; and nitric oxide, N_2O_5 . From this latter by the addition of water is formed nitric acid:

Nitric acid is now official in two forms; the pure acid of the sp. gr. 1.403 at 25° C. (77° F.) and the diluted. The strong acid of the sp. gr. 1.5 has long been abandoned.

Preparation.—The usual practice adopted in the laboratory for obtaining nitric acid is to add to sodium nitrate in coarse powder contained in a retort, an equal weight of strong sulphuric acid, poured in by means of a tube or funnel, so as not to soil the neck. The materials should not occupy more than two-thirds of the capacity of the retort. A receiver being adapted, heat is applied by means of a sand bath, moderately at first, but afterwards more strongly when the materials begin to thicken, in order to bring the whole into a state of perfect fusion. Red vapors will at first arise and afterwards disappear in the course of the distillation. Towards its close they will be reproduced, and their reappearance will indicate that the process is completed.

The proportion of equal weights, as above given, corresponding nearly to one molecule of sodium nitrate and one of sulphuric acid, is the best for operations on a small scale in the laboratory.

A practical disadvantage in this method of obtaining very strong nitric acid is that, owing to the high heat and the presence of the crystals, the retort is frequently fractured. Henry Trimble recommended adding one part of commercial nitric acid to two parts of strong sulphuric acid in a retort and distilling slowly until the nitric acid is all collected.

Lunge and Rey obtained pure, colorless, concentrated nitric acid by the following method: A quantity of nitric acid, prepared and deprived of coloring impurities in the usual manner, and containing 98.7 per cent. of absolute

nitric acid, was put into a retort together with twice its volume of absolute sulphuric acid (H_2SO_4), and distilled *in vacuo*, the pressure being reduced to 20 Mm. by means of a water-jet pump. This was found to be the only way to prevent the acid from becoming yellow. The connection between the neck of the retort and the receiver was effected by wrapping with asbestos paper and an external coat of moulder's clay. Great care was taken to insure the absence of organic matter. The distillation takes place at a temperature of 35° C. (95° F.), and the distillate was completely colorless. It contained 99.7 per cent. of HNO_3 . (*Am. Drug.*, June 1, 1891, 170; from *Zeit. An. Chem.*)

Monohydrated Nitric Acid. **Hydrogen Nitrate.**—This is the strongest liquid nitric acid that can be procured, and may be obtained by distilling one molecule of pure and dry sodium nitrate with one molecule of monohydrated sulphuric acid. One molecule of monohydrated nitric acid distills over, and one molecule of sodium bisulphate remains behind:

Acid of this strength is very difficult to make, and requires for its preparation the most elaborate attention to separate the superabundant water. According to Arthur Smith of London, acid dehydrated as far as possible is perfectly colorless, boils at 84° C. (184° F.), and has the sp. gr. 1.517 at 15.4° C. (60° F.), and nearly approaches, in composition, to a monohydrate. Acid of this strength, even at the boiling temperature, has not the slightest action on tin or iron. According to Kolb (*Ann. Ch. Phys.* [4], x, 140), the true HNO_3 has a sp. gr. at 15° C. (59° F.) as high as 1.530.

The acid of a former Br. Pharmacopœia, having the sp. gr. 1.5, is of a yellowish color, and strongly corrosive. Strictly speaking, it is hydrogen nitrate diluted with half a molecule of water. An acid of this strength is inconveniently strong, is constantly undergoing decomposition under the influence of light, and was consequently replaced by a pure acid of the density 1.42 at 15.5° C. (60° F.). This substitution was made in the U. S. Pharmacopœia of 1850, and in the British Pharm. of 1867.

Nitric Acid: sp. gr. (U. S.) 1.403 at 25° C. (77° F.) and (Br.) 1.42 at 15.5° C. (60° F.). This is the acid now official in both the U. S. and Br. Pharmacopœias. Acid of the density 1.5 was not usually found in commerce, and much pains was required to get it of that strength. Besides, acid of this density was not necessary for any process of the Pharmacopœia. Considerations of this kind induced the revisers of our national standard of 1850 to lower the strength of official nitric acid to about 1.42, its purity in other respects remaining the same. In the U. S. Pharmacopœia of 1890 the strength was again very slightly reduced from 1.42 to 1.414 at 15° C. (59° F.), since it has been shown that 68 per cent. acid has this specific gravity, the acid of U. S. P. 1880, of

¹ Add if the temperature is above, subtract if below, 25° C.

² Corresponding with a difference in specific gravity of 0.0001.

NOTE.—To find the per cent. of N₂O₅, multiply the per cent. of HNO₃ by 0.85712. To find the per cent. of NO₃, multiply the per cent. of HNO₃ by 0.98402.

To find the weight in grammes of HNO₃ in 100 Cc., multiply the specific gravity by the per cent. of HNO₃.

To find the volume per cent. of official Nitric Acid, multiply the "normality" by 6.579. For the volume per cent. of official Diluted Nitric Acid, multiply the "normality" by 59.52.

(See reference on page 52.)

the specific gravity of 1.42, having an inconvenient fraction in its percentage (69.4 per cent.). The specific gravity 1.403 given in the U. S. Pharmacopœia (8th Revision) is practically equivalent to that given in the U. S. Pharmacopœia of 1890 (1.414), the temperature used in the U. S. Pharmacopœia (8th Revision) for specific gravity being 25° C. (77° F.) instead of the lower one of 15.6° C. (60° F.). (See official table pp. 50-51.)

"Heated with indigo T.S., it discharges the blue color of the reagent. Even when highly diluted, it shows an acid reaction upon blue litmus paper. If 10 Cc. of the Acid be evaporated to dryness and further heated at 110° C. (230° F.), no appreciable residue should remain (limit of *non-volatile impurities*). Five Cc. of diluted Nitric Acid (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). Other portions of this dilution should not yield a precipitate upon the addition of barium chloride T.S. (absence of *sulphuric acid*); or of silver nitrate T.S. (absence of *hydrochloric acid*). Nitric Acid when neutralized with ammonia water and diluted with distilled water (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If the diluted Acid (1 in 3) be shaken with a few drops of chloroform, the latter should remain colorless (absence of *iodine* or *bromine*), even after the introduction of a small piece of metallic tin (absence of *iodic* or *bromic acid*). Introduce into a stoppered weighing-bottle 3 Cc. of Nitric Acid and weigh accurately. Dilute the Acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 6.257, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Nitric Acid in the latter." U. S. "Each gramme diluted with water should require for neutralization 11.1 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, chlorides, bromates, iodates, or sulphates. It should yield no residue or not more than 0.005 per cent. on evaporation to dryness." Br.

To correspond with the tests given in the U. S. P., it must be "a colorless, fuming liquid, very caustic and corrosive, and having a peculiar, somewhat suffocating odor. Specific gravity: about 1.403 at 25° C. (77° F.). It boils and is completely volatilized at 120.5° C. (248.9° F.). It dissolves copper, mercury, silver, and other metals with evolution of red fumes, and stains woollen fabrics and animal tissues a bright yellow." U. S. Acid of the density 1.42 at 15° C. is the most stable of the hydrated compounds of nitric acid, and boils at 121° C. (250° F.), the official acid boiling at 120.5° C. (248.9° F.). When either stronger or weaker than this,

it distills over at a lower temperature, and, by losing more acid than water in the first case, and more water than acid in the second, constantly approaches to the sp. gr. 1.42, when its boiling point becomes stationary. Dalton first observed these facts in relation to nitric acid of this strength, which have been confirmed by Arthur Smith of London. This acid may be assumed to have the composition $\text{HNO}_3 + \frac{1}{2}\text{H}_2\text{O}$.

The reddish acid called *aqua fortis* or *nitrous acid* is nitric acid containing more or less nitrogen tetroxide (N_2O_4). The same acid may be formed by impregnating, to a limited extent, nitric acid with nitrogen dioxide (N_2O_2). If the saturation be complete, every two molecules of nitric oxide become three molecules of nitrogen tetroxide by the aid of one molecule of nitrogen dioxide ($2\text{N}_2\text{O}_2 + \text{N}_2\text{O}_2 = 3\text{N}_2\text{O}_4$). More commonly it is obtained by distilling a mixture of 4 parts of starch and 100 parts of potassium nitrate with 100 parts of sulphuric acid. In this way the nitrogen tetroxide produced is at once taken up in the concentrated nitric acid and an acid of sp. gr. 1.50 is obtainable.

In making nitric acid on the commercial scale, sodium nitrate is substituted for potassium nitrate, as it is much cheaper, and the salt is decomposed with sulphuric acid as before. The proportions of these two substances employed are not the same in all works. If one molecule of sulphuric acid and two of sodium nitrate be taken, the following are the reactions:

When the heat is raised, the acid sodium sulphate acts upon a second molecule of sodium nitrate, thus:

In this case a part of the acid is decomposed, owing to the high temperature, and nitrogen peroxide is evolved in the form of red fumes, which dissolve in the concentrated acid, giving it the red appearance usually noted in the strong commercial product. When a large excess of sulphuric acid is employed, some acid sodium sulphate is formed, which lowers the melting point of the residual mass so that it can be withdrawn from the retorts in a fused state, whereas in the other case the residue can only be removed in the solid state after the cylinder has cooled.

The ordinary commercial acid has a specific gravity of from 1.30 to 1.41, and is usually prepared by means of chamber (sulphuric) acid; but if a more concentrated acid is required, a stronger sulphuric acid must be employed. The strongest nitric acid occurring in commerce has a sp. gr. of 1.43, and this is obtained by distilling well dried Chili saltpetre with sulphuric acid having a specific gravity of 1.85.

The retorts in which nitric acid is usually prepared in England consist of cast iron cylinders, built in a furnace in such a way that they may be heated as uniformly as possible. Some manufacturers cover the upper half of the cylinder with fire-bricks, in order to protect the iron from the action of the nitric acid vapors.

This is unnecessary, however, if the retorts are so thoroughly heated that no nitric acid condenses on the surface of the iron.

Mallet of Paris, has proposed to obtain nitric acid by distilling sodium nitrate with well dried boric acid, sodium biborate or borax being the residue. Another method, employed by Kuhlmann, is to expose a mixture of sodium nitrate and manganese chloride to a heat of about 232° C. (450° F.), and to pass the mixed gases which escape through water. Hypo-nitric acid and oxygen are disengaged, which become nitric acid when they enter the water. (P. J., 1862.)

Quite recently, the Atmospheric Products Company have attempted at Niagara Falls to manufacture nitric acid by effecting the direct union of the oxygen and nitrogen of the air by means of electric arcs of high voltage. By the use of revolving frames carrying a large number of discharging points which pass the opposite poles of high voltage currents, a large number of arc discharges per minute can be obtained, and a considerable formation of nitrogen oxides, which washed with water, yield nitric acid.

In this connection it may be stated that a trace of nitric acid has been detected in the atmosphere. It is said to be always present in the air in summer (Kletsinsky).

Properties.—Nitric acid, so called from nitre, is an extremely sour and corrosive liquid. It was discovered by Raymond Lully, in the thirteenth century, and its constituents by Cavendish in 1784. When perfectly pure it is colorless; but, as usually obtained, it has a straw color, owing to the presence of hyponitric acid. The concentrated acid, when exposed to the air, emits white fumes, possessing a disagreeable odor. By the action of light it undergoes a slight decomposition, and becomes yellow. It acts powerfully on animal matter, causing its decomposition. On the living fibre it operates as a strong caustic. It stains the skin and most animal substances an indelible yellow color. On vegetable fibre it acts peculiarly, abstracting hydrogen or water, and oxidizing the remaining elements. When diluted, nitric acid converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to other bodies, which it is enabled to do, as oxygen in the nascent state is liberated in its decomposition. If this liberation takes place while in contact with bodies capable of oxidation, the oxygen goes to effect this oxidation. Free nitric acid, however, will evolve oxygen at a red heat, according to the following reaction:

It oxidizes sulphur and phosphorus, giving rise to sulphuric and phosphoric acids, and all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. It combines with salifiable bases and forms nitrates. When mixed with

hydrochloric acid, mutual decomposition takes place, according to the reaction

and nitrohydrochloric acid is formed.

Great care must be used in transporting nitric acid, for if the strong acid comes in contact in quantity with vegetable substances like hay, tow, excelsior, paper, etc., fire will be apt to occur. The cause of such accidents was proved by the official inquiry of R. Hass. (*Ber. d. Chem. Ges.*, 1881, 597.)

Tests.—Nitric acid, when uncombined, is recognized by its dissolving copper with the production of red vapors. When in the form of a nitrate, it is known by its action on gold leaf, after the addition of hydrochloric acid, in consequence of the evolution of chlorine; or it may be discovered, according to O'Shaughnessy, by heating the supposed nitrate in a test tube with a drop of sulphuric acid, and then adding a crystal of morphine. If nitric acid be present, it will be set free by the sulphuric acid, and reddened by the morphine. The same effect is produced by brucine, by commercial strychnine, on account of its containing brucine, and still more strongly, according to Braun, by aniline sulphate, which affords an exceedingly delicate test. (*J. P. C.*, 1867, p. 157.) To prevent all ambiguity arising from the accidental presence of nitric acid in the sulphuric acid employed, the operator should satisfy himself, by a separate experiment, that the latter acid has no power to produce the characteristic color with morphine. Another test for nitric acid is to add pure sulphuric acid to the concentrated liquid suspected to contain it, together with a little concentrated solution of ferrous sulphate. The smallest trace of nitric acid affords, when the mixture is warmed, a pink red color; and if it be present in considerable amount, the liquid becomes almost black. Rosa recommends the use of ammonio-ferrous sulphate in place of ferrous sulphate, as a test for nitric acid. It is more stable than the latter, either in crystals or in solution. Equal measures of the liquid to be tested for nitric acid and of concentrated sulphuric acid are mixed, the mixture cooled, and then a layer of solution of ammonio-ferrous sulphate poured slowly on top; if even a trace of nitric acid be present, a brown zone will form at the line of contact of the liquids. (*Am. Drug.*, 1886, p. 13.)

A method particularly useful in the determination of the nitrates contained in drinking-water depends upon the fact that a thin zinc plate, which has been covered with a deposit of spongy metallic copper by dipping it in a solution of copper sulphate, on being heated with water containing nitrates, reduces them to ammonia, zinc hydroxide and free hydrogen also being formed (Gladstone and Tribe). The reaction with hydrogen is as follows:

Composition.—Nitric oxide or anhydride consists of two atoms of nitrogen and five atoms of oxygen; or, in volumes, of two volumes of

nitrogen and five volumes of oxygen, supposed to be condensed into two volumes to form nitric oxide vapor. In 1849 the interesting discovery was made by Deville of Besançon, of the means of isolating nitric acid oxide or anhydride. The method pursued was to pass perfectly dry chlorine over silver nitrate. The oxide is in the form of colorless brilliant limpid crystals, which melt at 29.5° C. (85° F.) and boil at 45° C. (113° F.). In contact with water they form a colorless solution with evolution of heat, without the disengagement of gas. (J. P. C., 1849, p. 207.)

Uses.—Nitric acid is tonic, antiseptic, astringent, and appears to act upon the intestinal glands in some way so as to modify their function. It is a very useful remedy in cases of *intestinal indigestion*; in this it resembles hydrochloric acid, and the choice between the two acids in any individual case should be guided by the existence or non-existence of diarrhoea, the nitric acid being given when there is looseness of the bowels. In *syphilis*, and in the *chronic hepatitis* of India, this acid was highly extolled by Scott, formerly of Bombay. It has occasionally excited ptyalism. It cannot be depended upon as a remedy in syphilis, but, in worn-out constitutions, is often an excellent adjuvant. In hepatic troubles it is markedly inferior to the nitrohydrochloric acid, unless, it may be, when there is much diarrhoea. As nitric acid dissolves both *uric acid* and the *phosphates*, it was supposed to be applicable to cases of *gravel* in which the uric acid and the phosphates are mixed, but experience has not confirmed the opinion. Nevertheless, when the sabulous deposit depends upon disordered digestion, this acid may prove serviceable by restoring the tone of the stomach. For internal use it should be well diluted and taken through a glass tube to avoid injury to the teeth.

Externally, nitric acid has been used with advantage as a lotion to *ulcers*, in the strength of about twelve minims to the pint of water. This practice originally suggested by Everard Home is practically applicable to those *ulcers* which are superficial and not disposed to cicatrize. In sloughing *phagedæna*, strong nitric acid is one of the best remedies, applied by means of a piece of lint tied around a small stick, or by the use of a glass brush. Sometimes a piece of lint is soaked with the strong acid, and pressed into the sore, being allowed to remain for several hours. In *cancrem oris*, concentrated nitric acid, freely applied, is one of the best local remedies that can be employed for arresting the phagedænic ulceration and disposing the sore to heal, but great care must be exercised to protect the teeth. The strong acid is also used as an escharotic in *venereal ulcers* and other affections. Nitric acid vapors were formerly used as a disinfectant. Half an ounce of powdered potassium nitrate was put into a saucer, placed in an earthen dish containing heated sand, and two drachms of sulphuric acid were then poured over it.

Toxicology.—The swallowing of concentrated nitric acid is immediately followed by burning heat in the mouth, œsophagus, and stomach, acute pain, disengagement of gas, abundant eructations, nausea, and hiccough. These effects are soon followed by repeated and excessive vomiting of matter having a peculiar odor and taste, tumefaction of the abdomen with exquisite tenderness, a feeling of coldness on the surface, horripilation, icy coldness of the extremities, small depressed pulse, great anxiety, continual tossings and contortions, and extreme thirst. The cases are almost always fatal. Sometimes the collapse has been immediate and has masked all the other symptoms. The best remedies are repeated large doses of alkaline solutions, soap, magnesia, and chalk, as antidotes, mucilaginous drinks, olive or almond oil in large doses, emollient fomentations, etc.

Dose, five to ten minims (0.3 to 0.6 Cc.), largely diluted.

ACIDUM NITRICUM DILUTUM.

U. S., Br.

DILUTED NITRIC ACID

(âc'î-dûm ní'trí-cûm dî-lú'tûm)

"Diluted Nitric Acid should contain 10 percent., by weight, of absolute Nitric Acid [HNO_3 or $\text{NO}_2.\text{OH} = 62.57$], and 90 percent. of water." U. S. "100 parts by weight should contain 17.44 parts of hydrogen nitrate, HNO_3 ." Br.

Acide azotique diluée, Fr.; Verdünnte Salpetersäure, G.; Acido nitrico diluito, It.

* "Nitric Acid, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, five hundred and eighty grammes [or 20 ounces av., 201 grains], to make six hundred and eighty grammes [or 23 ounces av., 432 grains]. Mix them. Keep the product in dark amber-colored, glass-stoppered bottles." U. S.

"Nitric Acid, 3 fl. ounces and 7 fl. drachms (more exactly, 3.86 fl. ounces, Imperial measure) or 2400 grains, or 193.2 cubic centimetres or 274.3 grammes; Distilled Water, a sufficient quantity. Introduce the Nitric Acid into a glass flask, the capacity of which to a mark on the neck is one pint (Imp. meas.) or one thousand cubic centimetres; add Distilled Water until the mixture, at 60° F. (15.5° C.), measures one pint (Imp. meas.) or one thousand cubic centimetres." Br.

The U. S. acid, as now directed, does not vary appreciably from that formerly official. "Specific gravity: about 1.054 at 25° C. (77° F.). It should respond to the reactions and tests given under *Acidum Nitricum*. To neutralize 6.26 Gm. (6.257 Gm.) of Diluted Nitric Acid should require 10 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 1 percent. of absolute Nitric Acid), methyl-orange T.S. being used as indicator." U. S.

The British diluted acid is considerably stronger than our own in the same measure. It has the sp. gr. 1.101; and "each gramme should require for neutralization 2.7 cubic centimetres of the *volumetric solution of sodium hydroxide*." Br. In making the U. S. diluted acid, pharmacists should be careful to use acid of the sp. gr. 1.403; or, if the acid be weaker, to add proportionally less water; otherwise the diluted acid would be weaker than is directed in the Pharmacopœia.

The medicinal properties of the diluted acid are the same as those of the strong acid. (See *Acidum Nitricum*.)

Dose, of U. S. diluted acid, from twenty to forty minims (1.3 to 2.5 Cc.), of the British, from fifteen to thirty minims (0.9 to 1.8 Cc.), properly diluted.

ACIDUM NITROHYDROCHLORICUM.

U. S.

NITROHYDROCHLORIC ACID [Nitromuriatic Acid]

(ăc'ī-dūm nī-trō-hŷ-drō-phiłō'rī-cūm)

Acidum Nitromuriaticum, U. S. P. 1870; Aqua regia, Aqua-regis; Acide chlorazotique, Eau régale, Fr.; Acidum Chlorotitrosum; Salpetersalzsaure, Königswasser, G.

* "Nitric Acid, one hundred and eighty cubic centimeters [or 6 fluidounces, 42 minims]; Hydrochloric Acid, eight hundred and twenty cubic centimeters [or 27 fluidounces, 5 fluidrachms, 49 minims], to make about one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Acids in a capacious glass vessel, and, when effervescence has ceased, pour the product into dark amber-colored, glass-stoppered bottles, which should not be more than half filled, and which should be kept in a cool place."¹ U. S.

Nitrohydrochloric acid is the *aqua regia* of the earlier chemists, so called from its property of dissolving gold. Nitric and hydrochloric acids, when mixed together, are mutually decomposed. According to the researches of Gay-Lussac, the reaction gives rise to two compounds, NO₂Cl (nitroxyl chloride) and NOCl (nitrosyl chloride), mixed with free chlorine. Later researches seem, however, to show that the latter of the two chlorides exclusively is produced, the reaction for the decomposition of nitrohydrochloric acid being:

The power of nitrohydrochloric acid to dissolve gold and similar metals having a weak affinity for oxygen, is owing exclusively to the free chlorine present, and is in no wise dependent on the compound above referred to, which remains entirely passive during the solution of the metal. When nitrohydrochloric acid is made from strong acids, there is always a loss of the nitrosyl chloride and of free chlorine by effervescence, in consequence of the acids not containing sufficient water to hold the gaseous products in solution.

Properties.—"A golden-yellow, fuming, and very corrosive liquid, having a strong odor of chlorine. Completely volatilized by heat. It readily dissolves gold leaf, and a drop of it, when added to potassium iodide T.S., liberates iodine." U. S. Nitrohydrochloric acid has an orange color, soon changing to a golden yellow, and the odor of chlorine. It should be kept in a cool dark place, on account of its liability to lose chlorine by heat, and to have its chlorine converted into hydrochloric acid by the action of light and the decomposition of water. On account of its tendency to decomposition, it should not be made in large quantities, nor be kept very long by the apothecary; and care should be taken not to transfer it to the bottle in which it is to be dispensed, until effervescence has ceased, lest the pressure within should drive out the stopper. Nitric and hydrochloric acids, as found in commerce, are sometimes so weak that when mixed they will not readily act on gold leaf. In this case their solvent power may be rendered effective by the addition of a little sulphuric acid, which, by its superior affinity for water, concentrates the other acids, and causes immediate action.

Uses.—Nitrohydrochloric acid was brought to the notice of the profession in consequence of the favorable report of its efficacy as an external remedy in *hepatitis*, made by Scott, formerly of Bombay. When thus employed, it produces a tingling sensation of the skin, thirst, a peculiar taste in the mouth, and occasional soreness of the gums and plentiful ptialism, and at the same time stimulates the liver, as is evinced by an increased flow of bile. It is used either by sponging or in the form of a local or general bath. When applied by sponging, the acid is first diluted so as to have the sourness of strong vinegar. When used as a foot bath, three gallons of water, contained in a deep narrow wooden tub, may be acidulated with six fluidounces of the acid. In this the feet and legs are to be immersed for twenty minutes or half an hour. The bath may be employed at first daily, and afterwards twice or thrice a week; and the sponging may be used at the same time. The bath is said to be effective in promoting the passage of *biliary calculi*. The solution, prepared for a bath as above mentioned, may be used for a week, adding to it daily a pint of water acidulated with two fluidrachms of the acid, to make up for the waste by evaporation. The bath should have a temperature of about 97°

¹ For an apparatus for making nitrohydrochloric acid upon a large scale, see *P. J.*, xl. 422.

F., which may be attained by heating part of the acid solution in a non-metallic container and throwing it back into the remainder.

Nitrohydrochloric acid is much used internally and it is an excellent remedy in chronic *hepatic affections*, in *oxaluria*, and in *dyspepsia* with a tendency to constipation. It is sometimes given also in *syphilitic diseases*. The freshly prepared strong acid is preferable to the diluted, and should be given well diluted, after meals, care being exercised to prevent its injuring the teeth. It should never be prescribed in combination with strong alcoholic liquids undiluted, as gases may be generated in sufficient volume to cause explosion. (See *A. J. P.*, 1878, 67.)

Dose, three to six minims (0.2 to 0.4 Cc.).

ACIDUM NITROHYDROCHLORICUM DILUTUM. U. S., Br.

DILUTED NITROHYDROCHLORIC ACID [Diluted
Nitromuriatic Acid]

(äc'î-düm nî-trô-hÿ-drô-ghlô'rî-cüm dî-lû'tüm)

"An aqueous solution of free chlorine, hydrochloric, nitric, and nitrous acids." *Br.*

Acidum Nitromuriaticum Dilutum, U. S. P. 1870; Acide chlorazotique diluë, *Fr.*; Verdünnte Salpetersäure, *G.*

* "Nitric Acid, forty cubic centimeters [or 1 fluidounce, 2 fluidrachms, 49 minims]; Hydrochloric Acid, one hundred and eighty-two cubic centimeters [or 6 fluidounces, 74 minims]; Distilled Water, seven hundred and seventy-eight cubic centimeters [or 26 fluidounces, 2 fluidrachms, 28 minims], to make about one thousand cubic centimeters [or 33 fluidounces 6½ fluidrachms]. Mix the Acids in a capacious glass vessel, and, when effervescence has ceased, add the Distilled Water. Diluted Nitrohydrochloric Acid should be kept in dark amber-colored, glass-stoppered bottles, in a cool place. It should not be dispensed unless recently prepared." *U. S.*

"Nitric Acid, 3 fl. ounces (Imperial measure) or 60 cubic centimetres; Hydrochloric Acid, 4 fl. ounces (Imp. meas.) or 80 cubic centimetres; Distilled Water, 25 fl. ounces (Imp. meas.) or 500 cubic centimetres. Mix the Acids with the Distilled Water, and keep the mixture in a glass-stoppered bottle for fourteen days before it is used. Colorless, with a pungent acid taste and odor. Specific gravity 1.07. 4 grammes should require for neutralization about 10 cubic centimetres of the volumetric solution of sodium hydroxide." *Br.* "A colorless or pale yellowish liquid, having a faint odor of chlorine, and a very acid taste. It is completely volatilized by heat. When it is added to potassium iodide T.S., iodine is liberated." *U. S.*

Between diluted nitric and hydrochloric acids no reaction occurs, and therefore the U. S. Pharmacopœia directs that the acids shall be mixed before dilution. But according to the researches of Tilden, confirmed by Redwood (*P. J.*, x. 508), water determines a decomposi-

tion of the products resulting from the reaction between nitric and hydrochloric acids, and the re-formation of hydrochloric and nitric acids, with a little nitrous acid. It would seem, therefore, that diluted nitrohydrochloric acid is not an eligible preparation, a conclusion confirmed by clinical experience.

Dose, from ten to twenty minims (0.6 to 1.3 Cc.).

ACIDUM OLEICUM. U. S., Br.

OLEIC ACID

(äc'î-düm ô-lë'î-cüm)

$\text{HC}_{18}\text{H}_{33}\text{O}_2 = 280.14$

"A monobasic organic acid, prepared in a sufficiently pure condition by cooling commercial Oleic Acid to about 5° C. (41° F.), then separating and preserving the liquid portion." *U. S.* "Oleic Acid, $\text{CH}_3(\text{CH}_2)_7\text{CH} : \text{CH}(\text{C}_6\text{H}_5)_2\text{COOH}$, or hydrogen oleate, is obtained by the saponifying action of alkalies and subsequent action of acids, or by the action of superheated steam, upon the olein of fats. Usually not quite pure." *Br.*

Acidum oleicicum, Acidum elainicum; Elaic acid; Acide oléique, *Fr.*; Oleinsäure, Elainsäure, Oel-säure, *G.*

This acid, although known for many years, was not used medicinally until 1872 (*L. L.*, 1872, 709), when John Marshall introduced the oleates to the profession as substitutes for some of the older ointments, stating that they are not only cleaner and more elegant, but also much more efficacious. (See *Oleata*.)

Preparation.—The difficulty in preparing oleates of good quality arises usually from the use of the commercial oleic acid, which, being obtained as a by-product in the manufacture of glycerin and candles, has a reddish-brown color and a disagreeable fatty odor. It is almost always contaminated with stearic and palmitic acids, with undecomposed glycerides when obtained by the autoclave process, and hydrocarbons when obtained by the distillation of the fat acids. Various processes have been suggested for the purification of oleic acid. Charles Rice (*A. J. P.*, xlv. 2) exposes the commercial acid to a temperature of 4° C. (39° F.), and expresses the liquid portion, which is oleic acid deprived of the greater part of the contaminating substances. The odorous and coloring principles are not removed by this process. A writer in *A. J. P.* (xlv. 97) prepares oleic acid for making oleates by saponifying almond oil with potassium hydroxide; decomposing by tartaric acid, separating the precipitated bitartrate, heating for several hours on a water bath with half its weight of finely powdered lead oxide; after cooling, mixing with three times its volume of ether, settling, decanting, and treating the residue with ether as before; agitating the mixed ethereal solutions with diluted hydrochloric acid; skimming off the ethereal solution of oleic acid, washing

it with water, reskinning, and recovering the ether by distillation. Wolff (*A. J. P.*, 1879) saponifies oil of sweet almond with lead oxide, agitates the lead soap in petroleum benzin, which retains lead oleate in solution, the lead palmitate being deposited. The benzin solution of lead oleate is shaken repeatedly with diluted hydrochloric acid (1 to 7), when lead chloride separates, and a benzin solution of purified oleic acid is left; finally the benzin is driven off by evaporation. The objection to this process is the difficulty of freeing the oleic acid from traces of a disagreeable benzin odor. Saunders (*N. R.*, June, 1880) makes a solution of 5 pounds of white castile soap in 20 pounds of boiling water, adds 10 ounces of sulphuric acid, and boils with stirring, until two clear layers are formed. The upper layer is decanted, shaken with 5 pounds of hot water, and the oily layer again decanted; 4 ounces of lead oxide are dissolved in it with a gentle heat, and while hot, 5 pounds of alcohol, previously heated to 65.5° C. (150° F.), are added. It is filtered after standing 24 hours, and 1 ounce of hydrochloric acid shaken with the filtrate; 10 pounds of water are added, the acid decanted, again washed with 10 pounds of water, and finally recovered; the yield is about 2½ pounds. See also process by Charles T. George (*A. J. P.*, 1881, p. 379). Low grade oleic acids, obtained by the distillation of wool-grease, etc., may contain cholesterol and other unsaponifiable materials from this source (Allen). Commercial oleic acid is often adulterated with linoleic acid. Hazura claims to be able to show the presence of one per cent. of this by saponifying the mixture and then adding potassium permanganate. (For details see *A. J. P.*, 1889, p. 356.) Grandval and Valser (*Chem. News*, 1890, p. 85) give the following tests for linoleic acid: If a thin layer of the fraudulent oleic acid be placed upon a slip of lead scraped quite clean, and some pure oleic acid be put upon a similar slip of lead for comparison, the next day the impure acid will be more or less resinified, while the pure acid will be scarcely altered. If some drops of oleic acid adulterated with linoleic acid be mixed with an equal volume of soda lye, an intense yellow color will be produced; pure oleic acid, if similarly treated, will merely take a grayish tint. Commercially, oleic acid is now obtainable by the recently described process of decomposition of fatty oils by the action of enzymes. For this purpose, the ferment of the castor oil bean has proven most efficient. Connstein has described the technical application of this process in a paper read at the *International Congress of Applied Chemistry* held at Berlin in 1903. (Vol. ii, p. 537.) For a paper on the esterification of oleic acid in the presence of a pancreatic ferment, by H. Pottevin, see *P. J.*, 1904, 492.

Properties.—“A yellowish or brownish-yellow, oily liquid, having a peculiar, lard-like odor and taste; becoming darker and absorb-

ing oxygen on exposure to air. Specific gravity: about 0.895 at 25° C. (77° F.). Insoluble in water; soluble in alcohol, chloroform, benzene, petroleum benzin, and fixed and volatile oils. When cooled to about 4° C. (39.2° F.), Oleic Acid becomes semi-solid, and on further cooling, congeals to a whitish, solid mass. When heated to a temperature of about 95° C. (203° F.), decomposition commences, and acrid vapors are produced. At a higher temperature it is completely dissipated. An alcoholic solution of Oleic Acid has a feebly acid reaction upon blue litmus paper. Equal volumes of Oleic Acid and alcohol, mixed at the ordinary temperature, should yield a clear solution without the separation of any oily drops (absence of *fixed oils*). If 1 Gm. of Oleic Acid be heated with 20 Cc. of alcohol, and 2 drops of phenolphthalein T.S. be added, followed by a strong solution of sodium hydroxide (1 in 4), drop by drop, until the liquid has acquired a permanent red tint and the acid is saponified, and if acetic acid be added until the red color of the liquid is just discharged, and the liquid be filtered, then 10 Cc. of the filtrate mixed with 10 Cc. of ether should not be rendered more than slightly turbid by shaking with 1 Cc. of lead acetate T.S. (absence of notable quantities of *palmitic* and *stearic acids*).” *U. S.* According to Dieterich, pure oleic acid has the iodine figure 89.8 to 90.05 and commercial oleic acid 65.03 to 86.18 (see PART III, Iodine Absorption Value of Fats and Oils, Test 51; also *Ph. Post*, 1894, 436.)

“At 40° to 41° F. (4.5° to 5° C.) it becomes semi-solid, melting again at 56° to 60° F. (13.3° to 15.5° C.). . . Dissolve about 1 gramme of the Acid in 15 to 20 times its volume of *alcohol* (90 per cent.); add two drops of *solution of phenolphthalein* and, drop by drop, a 25 per cent. aqueous solution of *sodium hydroxide* until the liquid after shaking remains slightly red and the acid is completely neutralized; then drop in *diluted acetic acid* until, after shaking, the red tint just disappears; filter the liquid, and mix about 10 cubic centimetres of it with an equal volume of Purified Ether and 1 cubic centimetre of a 10 per cent. aqueous solution of *lead acetate*; only a slight turbidity should result (absence of more than traces of *stearic* or *palmitic acid*).” *Br.*

Chemical Constitution.—Oleic acid, $C_{18}H_{34}O_2$, does not belong to the “fatty acid” series, but differs from the corresponding acid of that series, stearic acid, $C_{18}H_{36}O_2$, by having two atoms less of hydrogen. It belongs to a series derived by oxidation from alcohols which, like allyl alcohol, C_3H_5OH , have two atoms of hydrogen less than the normal monatomic alcohols, like propyl alcohol, C_3H_7OH . The alcohol from which oleic acid is in theory derivable is not, however, known. Oleic acid is monobasic, as shown in the formula $HC_{18}H_{33}O_2$.

Uses.—Oleic acid is used chiefly in preparing the oteates and in ointments. It has, however, been administered in capsules taken on first

rising in the morning as a substitute for olive oil in the treatment for *gallstones* (*R. T.*, 1901).

Dose, seven to fifteen grains (0.45 to 1 Gm.).

ACIDUM PHOSPHORICUM. U. S. (Br.)

PHOSPHORIC ACID

(ăc'ŭl-dŭm phos-phŏr'ŭl-cŭm)

"A liquid composed of 85 percent., by weight, of absolute Orthophosphoric Acid [H_3PO_4 or $\text{PO}(\text{OH})_3 = 97.29$], and 15 percent. of water. It should be kept in glass-stoppered bottles." *U. S.* "A liquid containing 66.3 per cent. of hydrogen orthophosphate, H_3PO_4 , with 33.7 per cent. of water. It may be prepared by treating, with water and nitric acid, the residue left after burning phosphorus in air." *Br.*

Acidum Phosphoricum Concentratum, *Br.*; Concentrated Phosphoric Acid; Acide Phosphorique, *Fr.*; Acidum phosphoricum, *P. G.*; Phosphorsäure, *G.*; Acido fosforico, *It.*, *Sp.*

The *U. S. P.* 1890 and 8th Rev. phosphoric acids are much stronger than that of the *U. S. P.* 1880; it is now 85 per cent., instead of 50 per cent. The United States Pharmacopoeia has very properly abandoned the former official process for this acid; it is more profitably and conveniently made on a large scale, and with such precautions and safeguards as cannot be easily used by the apothecary; the process of the *U. S. P.* 1880, however, will be found upon page 77, *U. S. D.*, 18th edition.

This preparation is recommended on account of its small bulk and its great convenience to the apothecary for preparing the diluted acid. The glacial phosphoric acid is no longer official, it having been shown that it is practically impossible to obtain it of sufficient purity to be reliable. (See *Proc. A. Ph. A.*, 1875, pp. 666, 672.) The present syrupy acid is a great improvement in every way, as it can be obtained of undoubted purity and strength, and by the addition of water, diluted phosphoric acid of any desired strength can easily be produced from it. The process for its preparation is the well known one of oxidizing phosphorus by the use of nitric acid, the former British method not differing materially from that of the *U. S. Pharmacopoeia* of 1880, except in the absence of the use of hydrogen sulphide for precipitating the arsenical compounds usually found in phosphorus, and in the greater strength of the finished product. The British concentrated phosphoric acid contains 66.3 per cent. of orthophosphoric acid, while the *U. S. phosphoric acid* now contains 85 per cent., and that of the German Pharmacopoeia is only 25 per cent. Phosphorus is oxidized at the expense of the nitric acid, any excess of nitric acid and all the

lower oxides of nitrogen being driven off by heat. Strong nitric acid acts too energetically on phosphorus, producing explosion and rapid combustion, but when diluted, as in the processes above referred to, it parts with its oxygen slowly, and it is even desirable to aid the operation with a gentle heat. Along with the nitrous fumes, a portion of the undecomposed nitric acid also rises in vapor, which, in the former British process, to prevent loss, is collected by means of a distillatory apparatus and returned to the retort. In the *U. S.* process of 1870 the same result was effected by placing over the liquid in the capsule a glass funnel, upon the inner surface of which the acid was condensed, and returned of itself into the capsule so as considerably to simplify the operation. This modification was originally suggested by Geo. W. Andrews of Baltimore, who, however, inverted a dish over the materials, the suggestion of the funnel being due to Procter. The operation was continued till the whole of the phosphorus was converted into phosphoric acid and dissolved; the liquid having been deprived of any remaining acid, and reduced to a certain weight by concentration, the process was completed by adding a certain measure of water, so that an acid of definite strength was obtained. C. L. Diehl found, in carrying this process into effect, that the glass funnel covering the capsule almost always breaks through the violence of the reaction, thus causing loss of phosphorus, besides annoyance to the operator. He therefore prefers using a French tubulated glass retort, and this suggestion was adopted in the process for Phosphoric Acid (*U. S. P.* 1880). (*A. J. P.*, 1867, p. 138.)

Markoe (*Proc. A. Ph. A.*, 1875, p. 677) proposed a method for making phosphoric acid which is particularly adapted for making large quantities, yet works well in a smaller way. Into a flask (or stone jar) having double the capacity of the materials used, 12 troyounces of water, 2 troyounces of phosphorus, and 10 grains of iodine are placed, then 40 grains of bromine are cautiously dropped in; when the reaction has ceased, 12 troyounces of nitric acid are added; a glass funnel is adjusted in the neck of the flask, and a smaller inverted funnel set inside of it; the apparatus is placed in a stoneware dish, and surrounded with cold water or ice; the reaction takes place slowly and regularly. In about 24 hours, if all the phosphorus be not acted upon, heat may be applied until it disappears, and the excess of bromine, iodine, and nitric acid is driven off. The acid may then be diluted to the desired specific gravity. J. U. Lloyd (*N. R.*, July, 1880) suggests the use of pure alcohol to unite with the nitric acid to form nitrous ether, which is more volatile and more easily driven off. Markoe added a small quantity of pure oxalic acid, and heated the mixture to 300° F.; at this temperature it is asserted that all the oxalic acid splits into carbon monoxide and carbon dioxide.

Nicolas prepares a pure phosphoric acid by adding a known quantity of pure calcium phosphate gradually to a slight excess of pure diluted hydrofluoric acid contained in a lead or platinum vessel, the mixture being well stirred after each addition. An energetic action takes place. When all the calcium phosphate has been added, the temperature is still maintained for a time to complete the reaction. The calcium fluoride is then filtered off and the solution evaporated. As the solution becomes viscid, the excess of hydrofluoric acid all passes off by evaporation. A syrup containing from 60 to 70 percent. of phosphoric anhydride can be thus obtained. Warren suggests a method for preparing phosphoric acid in a pure state, which consists in introducing sodium or other soluble phosphate into a solution of copper sulphate, washing the insoluble copper phosphate formed, and dissolving in solution of phosphoric acid, then electrolyzing the mixture. A pure and very dense copper is said to be thrown down, and a large quantity of phosphoric acid of sp. gr. 1.75 is obtained. (*Chem. News*, lxxiii. 66.)

Much dissatisfaction has been caused among pharmacists by the fact that diluted phosphoric acid frequently produces a white precipitate in solutions of ferric salts. An examination proved that this occurred when the glacial acid is used, or when high heat had been employed in the concentration. Experiments conducted by Louis Dohme and Remington indicated that the precipitation resulted from the presence of pyrophosphoric acid. (*Proc. A. Ph. A.*, 1874, 431, 511; 1875, 663, 670, 667.) Considerable difficulty was experienced in driving off all the nitric acid, and in the attempt to do so the temperature became so elevated as to reconvert some of the tribasic acid to the bibasic form. This occurred slightly at 148.8° C. (300° F.), but to a much greater extent between 176.6° C. (350° F.) and 204.4° C. (400° F.). The diluted acid, made from phosphorus, can be brought to the boiling point of 232.2° C. (450° F.), and will then only produce a slight cloud with tincture of ferric chloride, but if diluted, when cool, with about half its bulk of cold water, which causes considerable elevation of temperature, it forms a clear solution. The same acid evaporated, heated to redness, allowed to congeal, and then dissolved in water, precipitated the iron solution. The addition of twenty per cent. of sodium pyrophosphate to the same diluted acid made a preparation which in all respects resembled that made from the glacial acid, thus giving evidence that the presence of this contamination was the cause of the difference in the two preparations.

It has been suggested that red phosphorus might be substituted for common phosphorus, as producing the same results, with less danger of explosion; but the official process, when carefully followed in reference to due dilution and a moderate heat, is not dangerous.

Lyons's table (pages 60 and 61), now incorporated in the U. S. P. 8th Rev., exhibits

the quantity of orthophosphoric acid contained in solutions of different densities at 15° C. (59° F.) and 25° C. (77° F.).

Properties.—"A colorless liquid of a syrupy consistence, without odor, and having a strongly acid taste. Specific gravity: about 1.707 at 25° C. (77° F.). Miscible, in all proportions, with water or alcohol. When heated, the liquid loses water; at 200° C. (392° F.), it gradually begins to change to pyrophosphoric acid. At a still higher temperature it is converted into metaphosphoric acid, which volatilizes in dense fumes, or, on cooling, forms a transparent mass of glacial phosphoric acid. The Acid, even when largely diluted, has an acid reaction upon blue litmus paper. If a small portion of Phosphoric Acid be supersaturated with ammonia water, the addition of magnesium sulphate T.S. (or of magnesium mixture) produces a white, crystalline precipitate. If this precipitate be collected, washed, and dissolved in diluted acetic acid, the solution yields a yellow precipitate with silver nitrate T.S. (distinction from metaphosphoric or pyrophosphoric acid). If a crystal of ferrous sulphate be dropped into a cooled mixture of 1 Ce., each, of Phosphoric Acid, sulphuric acid, and water, no brown or brownish-black color should appear around the crystal (absence of *nitric acid*). If 1 Ce. of Phosphoric Acid be diluted with 5 Ce. of water, and the liquid gently warmed, it should not be blackened upon the addition of a few drops of silver nitrate T.S., or rendered turbid by mercuric chloride T.S. (absence of *phosphorous acid*). If Phosphoric Acid be diluted with water (1 in 10), 5 Ce. should not respond to the Modified Gutzzeit's Test for *arsenic* (see Part III, Test No. 17). Upon adding to 1 Ce. of Phosphoric Acid a mixture of 3 Ce. of alcohol and 1 Ce. of ether, no turbidity should appear (absence of *phosphates*). If Phosphoric Acid be diluted with water (1 in 20), 10 Ce. should not respond to the Time-Limit Test for *heavy metals* (see Part III, Test No. 121.) After diluting a portion of the Acid with 5 volumes of water, no precipitate should be produced, in separate portions of the liquid, by barium chloride T.S. (absence of *sulphuric acid*), or by silver nitrate T.S. (absence of *hydrochloric acid*); or when dropped into albumin T.S. (absence of *metaphosphoric acid*); nor should any precipitate be formed, even after several hours, by the addition of an equal volume of official tincture of ferric chloride (absence of *pyrophosphoric* and *metaphosphoric acids*). If 10 Gm. of Phosphoric Acid be diluted to measure 100 Ce., then 9.73 Ce. of this solution, when diluted with 10 Ce. of a cold saturated solution of sodium chloride, should require 17 Ce. of normal potassium hydroxide V.S. for neutralization (each Ce. corresponding to 5 percent. of absolute Phosphoric Acid), phenolphthalein T.S. being used as indicator." U. S.

"Evaporated, it leaves a residue which melts at a low red heat, and when cold forms a glass-like mass. The Acid yields, when neu-

¹ Add if the temperature is above, subtract if below, 25° C.

² Corresponding with a difference in specific gravity of 0.0001.

NOTE.—To find the per cent. of P_2O_5 , multiply the per cent. of H_3PO_4 by 0.7243. To find the per cent. of PO_4 , multiply the per cent. of H_3PO_4 by 0.96916.

To find the weight in grammes of H_3PO_4 in 100 Cc., multiply the specific gravity by the per cent. of H_3PO_4 .

To find the volume per cent. of official Phosphoric Acid, multiply the "normality" by 3.365. For the volume per cent. of official Diluted Phosphoric Acid, multiply the "normality" by 46.08.

tralized, the reactions characteristic of phosphates. Specific gravity 1.5. Each gramme of it mixed with 2.5 grammes of Lead Oxide in fine powder should leave on evaporation a residue which, after it has been heated to dull redness, weighs 2.98 grammes. It should yield, when diluted with water, no characteristic reaction with the tests for lead, copper, arsenium, calcium, potassium, sodium, ammonium, chlorides, or nitrates, and only slight traces of iron or sulphates. Diluted, with five or six times its bulk of water, it is not precipitated by solution of albumen (absence of metaphosphoric acid), nor on adding Tincture of Ferric Chloride and setting the mixture aside for several hours (absence of metaphosphoric and pyrophosphoric acids). Diluted with water

and the mixture set aside, no precipitate occurs (absence of silica). Diluted and mixed with an equal volume of test-solution of mercuric chloride and heated, no precipitate is formed (absence of phosphorous acid)." Br.

Uses.—This acid is used in making phosphates and lactophosphates. It has the same medicinal properties and uses as the diluted Phosphoric Acid (see p. 62).

Dose, two to five minims (0.12 to 0.3 Cc.).

ACIDUM PHOSPHORICUM GLACIALE.—(*Glacial Phosphoric Acid; Metaphosphoric Acid; Monobasic Phosphoric Acid; Monohydrated Phosphoric Acid; Acide phosphorique glacial, Fr.; Glasige Phosphorsaure, G.*) Formula HPO_3 ; mol. wt. 79.41.—Phosphoric oxide consists of two atoms of phosphorus and five atoms of oxygen, P_2O_5 , and can be obtained only by the direct union of its constituents, which takes place when phosphorus is burned in perfectly dry oxygen gas. Thus procured, it is in the form of a white amorphous powder, extremely deliquescent, volatilizable at a red heat, and assuming, when it cools after fusion, a vitreous appearance. The classic researches of Graham first established clearly the character of the several varieties of phosphoric acid, which may be considered as derived from this oxide.

When amorphous phosphorus is boiled with nitric acid, or when phosphoric oxide is boiled with water, the oxide takes up three molecules of water, and yields tribasic or *ordinary phosphoric acid* according to the reaction:

If this acid be heated for a considerable time to 215°C . (419°F .), the two molecules lose one mol. of water and yield *pyrophosphoric acid*, a tetrabasic variety, according to the reaction:

Lastly, at a red heat the ordinary phosphoric acid is converted into *metaphosphoric acid*, a monobasic variety, according to the reaction:

This last variety may also be obtained directly from the oxide by dissolving it in cold water, when it takes up one molecule of water:

An aqueous solution of either of the three acids, heated so long as water escapes, yields the monobasic or metaphosphoric acid; and as, upon cooling, it becomes a transparent ice-like solid, it has received in this state the name of *glacial phosphoric acid*. Conversely, this monobasic acid is slowly transformed, in aqueous solution, and more rapidly if the solution is heated, into the tribasic form. John M. Maisch ascertained that nitric acid, added to the solution of the monobasic acid, with the aid of heat, caused the change from the monobasic to the tribasic form, i.e., to the common phosphoric acid, without the intermediate production of the tetrabasic variety. *Pyrophosphorous Acid*, $\text{H}_4\text{P}_2\text{O}_7$, has been obtained by V. Auger in the form of colorless needles, melting at 38°C . (100.4°F .). (*C. R. A. S.*, 136, 814.)

Tests.—The three forms of phosphoric acid are distinguishable by peculiar reactions. Thus, the *monobasic* is characterized by coagulating albumin, and giving white, gelatinous, uncrystallizable precipitates with the soluble salts of barium, lime, and silver; the *tetrabasic* does not coagulate albumin, and, though it causes a white precipitate with silver nitrate, must first be neutralized; the *tribasic* does not coagulate albumin, and, until neutralized, does not pre-

cipitate silver nitrate, but after neutralization throws down a yellow precipitate of silver phosphate.

Glacial phosphoric acid is most advantageously obtained from calcined bones, by first treating them with sulphuric acid, which produces an insoluble calcium sulphate and soluble acid phosphate; then dissolving out the latter salt, and saturating it with ammonium carbonate, which generates ammonium phosphate in solution; and, finally, obtaining the ammonium phosphate by evaporation to dryness, and then igniting it in a platinum crucible. The ammonia and all the water except the one molecule needed for the formation of metaphosphoric acid are driven off, and the glacial acid remains.

Properties.—Glacial phosphoric acid is in the form of a white, uncrystallizable, fusible solid; inodorous, very sour to the taste, slowly deliquescent, slowly soluble in water, and soluble also in alcohol. Its formula is HPO_3 , and it is made up of 11.2 per cent. of water in combination with 88.8 per cent. of phosphoric oxide. It is characterized by producing white gelatinous precipitates with albumin, and with the soluble salts of lime, barium, and silver; and the precipitate produced with the barium chloride is readily redissolved by an excess of the acid. This form of acid results when the oxide, produced by burning phosphorus in dry oxygen gas, is introduced into cold water.

Impurities.—Glacial phosphoric acid is seldom prepared in this country. That found in commerce is almost all imported, and chiefly from Germany. It is often more or less impure, containing (as shown by the experiments of Maisch), silica and calcium and magnesium phosphates, which are precipitated from a neutralized solution of the acid by ammonia. In one instance 8 per cent. of these impurities was found, but in some others little or none. Maisch never found nitric or hydrochloric acid, and sulphuric acid rarely; and, though the presence of ammonia might be suspected from the source whence the acid is obtained, he did not detect it. (*A. J. P.*, 1860, p. 194.) The chief impurity, however, is soda, as has been pointed out by Brescius, Remington, Dohme, Prescott, and others (see *Proc. A. Ph. A.*, 1875, 666, 672); the acid has been found to contain occasionally as much as 60 per cent. of sodium metaphosphate, and rarely less than 55 per cent. (*N. R.*, Feb. 1879). Hodgkin (*P. J.*, 1891, p. 217) examined eight samples of German and English glacial phosphoric acid, and found in them, respectively, the following proportions of absolute orthophosphoric acid: 92.8, 91.5, 90.8, 85.4, 84.4, 83.8, 80.1, and 78.1 per cent. In consequence of its deliquescence upon exposure to the air, a portion of the monobasic acid passes into the tribasic state. This may be detected, if in considerable quantity, by its giving a yellowish colored precipitate with silver nitrate. The U. S. P. 1870 directed that the acid, in aqueous solution, should yield no precipitate with hydro-

gen sulphide, showing the absence of metals; should cause a white precipitate with barium chloride soluble in an excess of acid; with an excess of ammonia should cause only a slight turbidity, proving the almost total absence of earthy salts; and should yield no ammonia when treated with potassium hydroxide in excess. Should the presence of arsenic be ascertained by the tests for that metal, it may be separated by boiling with hydrochloric acid, so as to convert the arsenic into its very volatile chloride, which would escape with vapors of hydrochloric acid.

Glacial phosphoric acid was introduced into the U. S. P. 1860 as affording a convenient method of preparing the medicinal acid, but, owing to its unreliability, was very properly dismissed; $38\frac{1}{2}$ grains, dissolved in a fluidounce of water, form a solution about equal in strength to the diluted acid of U. S. P. 1860.

ACIDUM PHOSPHORICUM DILUTUM.

U. S., Br.

DILUTED PHOSPHORIC ACID

(ἀέτ'δὺμ φὸς-φὸρ'τ'δὺμ δι-λῦτὺμ)

"Diluted Phosphoric Acid should contain 10 percent., by weight, of absolute Orthophosphoric Acid [H_3PO_4 or $\text{PO}(\text{OH})_3=97.29$], and 90 percent. of water." U. S. "A liquid containing, by weight, 13.8 parts of hydrogen orthophosphate, H_3PO_4 , and 86.2 parts of water." Br.

Acide phosphorique médicinal, Fr.; Verdünnte Phosphorsäure, G.

* "Phosphoric Acid, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, seven hundred and fifty grammes [or 26 ounces av., 199 grains], to make eight hundred and fifty grammes [or 29 ounces av., 430 grains]. Mix them. Keep the product in glass-stoppered bottles." U. S.

"Concentrated Phosphoric Acid, 3 fl. ounces (Imperial measure) or 4.5 ounces, or 150 cubic centimetres or 225 grammes; Distilled Water, a sufficient quantity. Dilute the Concentrated Phosphoric Acid with sufficient Distilled Water to form, at 60°F . (15.5°C .), one pint (Imp. meas.) or one thousand cubic centimetres of Diluted Phosphoric Acid." Br.

It will be observed that in both Pharmacopœias diluted phosphoric acid is made by simple dilution of the stronger acid, and that the older method of dissolving the glacial acid has been very properly abandoned. (See *Acidum Phosphoricum Glaciale*, p. 62.) The official diluted acid is weaker than the British, the U. S. P. acid containing 10 per cent. of orthophosphoric acid, while the British contains 10 per cent. of phosphoric anhydride, P_2O_5 , which corresponds to about 14 (13.8) per cent. of orthophosphoric acid. The specific gravity of the British acid is 1.08, and "each gramme of it

mixed with 0.5 gramme of Lead Oxide in fine powder should leave on evaporation a residue which after it has been heated to dull redness weighs 0.6 gramme." Br.

Properties.—Diluted phosphoric acid is a colorless, inodorous, sour liquid, acting strongly on litmus, and possessing powerful acid properties, although when evaporated so as to become dense, it is not corrosive like the other mineral acids. Neubauer found that the strong acid, when pure and warm, was capable of dissolving calcium oxalate. Diluted Phosphoric Acid is officially described as follows: "Specific gravity: about 1.057 at 25°C . (77°F .). It corresponds in chemical properties and should conform to the reactions and tests given under *Acidum Phosphoricum*. If 4.87 Gm. of Diluted Phosphoric Acid be diluted with 5 Cc. of a cold saturated solution of potassium chloride, it should require 10 Cc. of normal potassium hydroxide V.S. for neutralization (each Cc. corresponding to 1 percent. of absolute Phosphoric Acid), phenolphthalein T.S. being used as indicator." U. S. It has been supposed that one-tenth of phosphorous acid would render the diluted acid dangerous to life; but experiments go far to show that this was an erroneous opinion, as half a drachm of that acid given to a dog produced no obvious poisonous effect. (See *A. J. P.*, 1858, p. 359.) Phosphorous acid may be detected by testing the medicinal acid with a solution of corrosive sublimate, which will be converted into calomel if this impurity be present.

Old diluted phosphoric acid is very apt to contain microscopic plants. The presence of traces of hydrochloric acid is said to prevent their formation. (Rother, *D. C.*, 1886, p. 99; L. E. Sayre, *Proc. A. Ph. A.*, 1885; Samuel G. Ade, *Proc. A. Ph. A.*, 1884.)

Uses.—Diluted phosphoric acid is deemed tonic and refrigerant. It is free from astringency, and is certainly a valuable remedy in many cases of *dyspepsia*. Various properties have been ascribed to it, such as allaying pain and spasm, strengthening the sexual organs, preventing the morbid secretion of bony matter, and correcting phosphatic deposits in the urine. The last two properties are supposed to depend upon its power of dissolving calcium phosphate. Diluted phosphoric acid has been recommended for use in the treatment of *hysteria*, *diabetes*, and *leucorrhœa* when the secreted fluid is thin and acrid; it has also been used with asserted good results in the treatment of *low fevers*, but probably has no action upon the system other than that upon the digestive organs, although A. Judson (*Ann. Thér.*, 1871 and 1872, p. 152) asserts that in doses of one to three drachms it acts as a stimulant, increasing the force and frequency of the pulse, and causing headache and cerebral confusion,—effects which may be the result of gastric irritation.

Dose, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.), largely diluted.

ACIDUM SALICYLICUM. U. S., Br.

SALICYLIC ACID

(äc'î-dûm sâl-î-cyl'î-cûm)

 $\text{HC}_7\text{H}_5\text{O}_3 = 137.01$

"A monobasic organic acid [$\text{C}_6\text{H}_4(\text{OH})\text{COOH}$ 1 : 2], existing naturally in combination in various plants, but generally prepared synthetically from phenol." U. S. "A crystalline acid, $\text{C}_6\text{H}_4\text{OH}.\text{COOH}$, obtained from natural salicylates such as the oils of wintergreen (*Gaultheria procumbens*, Linn.) and sweet-birch (*Betula lenta*, Linn.), or by the interaction of sodium carbolate and carbonic anhydride." Br.

Ortho-oxybenzoic Acid; Acidum Spiricum; Acide salicylique, Fr. Cod.; Acidum salicylicum, P. G.; Salicylsäure, Spärsäure, Salicylsäure, Spirolysäure, G.; Acido salicilico, It., Sp.

In 1834 salicyl aldehyde (*salicylous acid*) was discovered by Pagenstecker in the flowers of *Spiræa Ulmaria*, L. In 1837, Piria and Ettling found that by oxidizing agents salicyl aldehyde was converted into a new body, salicylic acid, and in 1839, Löwig and Weidmann derived the latter principle directly from the flowers of the *Spiræa Ulmaria*, L. Shortly afterwards Procter (A. J. P., 1843; Aug. 1875) discovered that the acid could be procured from the oil of wintergreen (*Gaultheria procumbens*), which is now known to contain fully 90 per cent. of methyl salicylate. Methyl salicylate is indeed obtainable by distillation from very many plants, but the probabilities are that it never exists already formed in the plant, but is produced during the process of distillation. (See *Betula lenta*, PART II.) When potassium hydroxide is added to methyl salicylate, a new salt is formed, from which the acid is readily obtained by means of hydrochloric acid. Notwithstanding the discovery of this fact, and also the invention of still another process of manufacture by Ettling in 1845, salicylic acid remained so expensive as to be of no value in the arts until Kolbe and Lautemann discovered that it could be prepared by uniting phenol with carbon dioxide through the instrumentality of sodium. The article now began to attract some attention, but remained beyond the reach of general use until Kolbe, by continuing his researches, succeeded, in 1874, in producing it at a moderate cost (*J. Pr. Chem.*, July, 1874). Traphagen and Burke found salicylic acid to be a natural constituent of many fruits, as follows: strawberries, raspberries, blackberries, currants, plums, black cherries, apricots, peaches, grapes, crab apples, apples, and oranges. (*J. Am. C. S.*, 1903, 242.)

Preparation.—While salicylic acid may be prepared from salicin by fusion with potassium hydroxide, or from oil of wintergreen by saponification with potassium hydroxide solution, practically it is now obtained, according to Kolbe's patent, by treating sodium phenol (or carbolate) with carbon dioxide gas. For this purpose, the most concentrated caustic soda solution is evaporated with the corre-

sponding amount of phenol to a dry powder, which is then heated to 100°C . (212°F .), while a stream of dry carbon dioxide gas is passed over it. The temperature is gradually raised to 180°C . (356°F .), increased to 220°C . (428°F .) as soon as phenol distills over, and finally raised to 250°C . (482°F .), until no more phenol distills. In the retort, the half of the phenol used remains as basic sodium salicylate, while the other half has distilled over unchanged. The reaction is as follows:

The sodium salt thus obtained is dissolved in water, decomposed by hydrochloric acid, the salicylic acid filtered off, washed, and crystallized out of hot water, or purified by sublimation in a current of superheated steam. P. W. Hofmann subsequently patented a process whereby distillation with superheated steam, with its attendant loss, is obviated; to the crude solution is added stannous chloride, which precipitates a dark mass containing the impurities, the clear supernatant liquid is then decomposed with hydrochloric acid and the crystals of salicylic acid purified by washing and the use of centrifugals. (*Ph. Centralh.*, 1892, 412.) An important improvement was subsequently made in Kolbe's process whereby all, instead of only half, of the phenol-sodium is converted into salicylate. R. Schmitt has found (Wagner's *Jahresbericht für Chem. Tech.*, 1885, p. 490) that if dry sodium phenolate and dry carbon dioxide are allowed to act on each other at ordinary temperatures, as long as absorption takes place a phenyl-sodium carbonate, $\text{CO} \left\{ \begin{array}{l} \text{OC}_6\text{H}_5 \\ \text{ONa} \end{array} \right.$, is formed. If this is now

heated for several hours in a closed vessel to 140°C ., a molecular rearrangement takes place, and simple sodium salicylate, $\text{C}_6\text{H}_4(\text{OH})\text{COONa}$, is formed without any separation whatever of phenol. Schmitt's process was purchased by the owners of Kolbe's patent. Lloyd's process for preparing salicylic acid from oil of wintergreen is as follows: Pure wintergreen oil, 3 parts; white potassium hydroxide, 3 parts; hydrochloric acid, 8 parts; water, q. s. Dissolve the potassium hydroxide in two parts of water in a glass or porcelain vessel, and heat to the temperature of 180°F . Stir into this gradually the oil, using a glass or porcelain spatula. Into another vessel place 64 parts of cold distilled water, and add the hydrochloric acid. Then with constant stirring add the solution of the potassium salicylate. The magma of minute crystals of salicylic acid must be separated with a thin muslin strainer (previously moistened) and pressed, then dried by exposure to a temperature of 150°F . The yield of this crude acid will be slightly over two parts. Dissolve this in six parts of cold alcohol, and filter through a funnel stopped with cotton. Then with constant stirring pour the filtrate into 32 parts of cold water. The magma of minute crystals must be separated with a thin

muslin strainer, and dried by exposure to a heat of 150° F. The yield is a trifle less than 2 parts. For Walter's process, see *Bull. Pharm.*, 1899, 54. Salicylic acid has also been obtained synthetically from copper benzoate and water, which, when heated together in sealed tubes, yield cuprous oxide, free benzoic acid, and salicylic acid. (E. F. Smith, *Am. Chem. J.*, 2, p. 338.) A. Rautert has found that the acid volatilizes with steam of 170° C. (338° F.), and has devised a process of purification based upon this, which yields at very little cost a beautiful product. Biel (*Ph. Z. R.*, 1876) reports that the sublimed acid is liable to decompose spontaneously. Dialyzed salicylic acid of beautiful appearance has been in the market since 1876. All traces of tarry matter can be removed by dialysis, and this acid is unexceptionable. Kolbe also obtained salicylic acid from barium and calcium carbolates, but the yield was less than when sodium salt was employed. Potassium phenol yielded only a trace of salicylic acid, but an abundance of *para*-oxybenzoic acid.

Properties.—Salicylic acid, when pure, occurs as a snow-white crystalline powder, free from odor, and also from taste, but leaving a sense of astringency on the tongue and of irritation in the fauces, with an increased flow of saliva. "Light, fine, white, prismatic needles, or a bulky, white, crystalline powder; odorless, or having a slight gaultheria-like odor, with a sweetish, afterwards acid taste, and permanent in the air." *U. S.* To the mucous membrane of the nose it is irritating, and it will sometimes produce sneezing. It crystallizes out of its hot aqueous solution on cooling in slender, often very long needles, and on the spontaneous evaporation of its alcoholic solution, in large four-sided prisms. It is strongly acid, acting decisively on blue litmus, and forming salts not only with alkalies, but also with metallic oxides. Salicylic acid is "soluble in 308 parts of water and in 2 parts of alcohol at 25° C. (77° F.); in 14 parts of boiling water, and very soluble in boiling alcohol; also soluble in ether, absolute alcohol, and chloroform. When heated to 156° C. (312.8° F.), the Acid begins to melt, and is completely melted at 157° C. (314.6° F.); at a higher temperature it is gradually dissipated without leaving more than 0.6 percent. of fixed residue. The saturated aqueous solution has an acid reaction upon blue litmus paper, and is colored intensely bluish-violet (in high dilution violet-red) by ferric chloride T.S." *U. S.* "Soluble in 3 parts of alcohol (90 per cent.), in 2 of ether, or in 200 of glycerin. Dissolves in solutions of ammonium citrate, ammonium acetate, sodium phosphate, and in solution of borax; also in solutions of alkaline hydroxides and carbonates, salicylates being produced; such solutions of salicylates, if not weaker than 1 per cent., afford a yellowish-brown precipitate with solution of uranium nitrate (distinction from carbolates and sulphocarbolates). The crystals melt at 312.8° to 314.6° F. (156° to

157° C.), and below 392° F. (200° C.) volatilize without decomposition. *Test-solution of ferric chloride* gives with the aqueous solution a violet color, or, if the solution be largely diluted, a reddish-violet color." *Br.* When heated rapidly it is converted into phenol and carbon dioxide. It is stated that, by careful heating, glycerin can be made to dissolve 1 part in 50, and that the solution not only remains clear on cooling, but also may be diluted with water without separating. (*A. J. P.*, 1875, p. 212.) Goldsborough affirms that a mixture of the acid with alcohol, 1 to 10, may be diluted with 150 parts of water without crystallizing. By the presence of various neutral salts its solubility is increased without its antiseptic value being interfered with. It dissolves when mixed with 1 part of potassium nitrate, in 50 parts water; 1½ parts of ammonium citrate, in 60 parts water; 2 parts sodium sulphite, in 50 parts water; 2 parts sodium phosphate, in 50 parts water; 2½ parts sodium phosphate, in 12½ parts water. (Allen, *Com. Org. Anal.*, 1879, p. 344; also see Rother, *A. J. P.*, 1886, p. 420.)

On distilling salicylic acid or one of its salts with methyl alcohol and sulphuric acid, acid methyl salicylate is formed, having an agreeable aromatic odor. The reaction with ferric salts is much more delicate (1 in 100,000) than that of phenol with the same reagent (1 in 3000). Commercial salicylic acid is often very impure. Sodium chloride, phenol, cresotic acid, and oxybenzoic and *para*-oxybenzoic acids are the usual impurities. The first of these substances remains on igniting the acid. Phenol may be detected by nearly neutralizing the sample with sodium hydroxide and agitating the liquid with ether. On evaporating, the ethereal liquid leaves the phenol, recognizable by its odor and taste. (Allen, *Com. Org. Anal.*, p. 347.)

The most sensitive test for it is a ferric salt, with which it develops a beautiful violet color. Goldsborough states that to insure the delicacy of this reaction it is necessary that the iron salt be perfectly neutral; also that with this precaution he has clearly detected 1 part of the acid in 400,000 parts of water. On the addition of ammonia the violet color is changed to a reddish-brown, then to an orange, then to a permanent greenish-yellow. Sulphuric and nitric acids change the violet to a light brown (Goldsborough). It must be remembered that salicylous acid reacts similarly with ferric salts. Salicylous acid, however, precipitates the silver potassio- or ammonio-nitrate white, the salicylic acid yellow. A. Fagans (*A. J. P.*, 1893, p. 133) points out that salicylic acid cannot be colorimetrically estimated in aqueous solutions in presence of phenols, but that in alcoholic solution only the former reacts with ferric chloride. Kolbe recommends a simple test to detect impurities. A little of the acid is dissolved in 10 times its weight of strong alcohol, and the solution allowed to evaporate spontaneously from a watch crystal. If the

salicylic acid which remains in the dish be perfectly colorless, the acid is strictly pure; it should not be of a brown color, although a slight yellowish color would not indicate sufficient impurity to affect its medicinal value. Hager states that pure salicylic acid equal in volume to the size of a bean produced, after agitation with about 5 Cc. of pure sulphuric acid, a colorless solution, while other samples which yielded a white residue from the alcoholic solution produced yellowish to brown-yellow solutions. (*A. J. P.*, June, 1877.)

By distilling with alcohol and strong sulphuric acid, salicylic acid forms methyl- and ethyl-salicylic acids.

Tests.—“On adding to a small portion of Salicylic Acid, in a test-tube, about 1 Cc. of concentrated sulphuric acid, then, cautiously, about 1 Cc. of methyl alcohol in drops, and heating the mixture to boiling, methyl salicylate will be produced, which may be recognized by its odor. On allowing a saturated alcoholic solution of the Acid to evaporate spontaneously in a glass or porcelain evaporating dish, in a place protected from dust, a perfectly white, crystalline residue should remain (absence of iron, phenol, or coloring matter). If 1 Gm. of the Acid be dissolved in an excess of cold sodium carbonate T.S., the liquid agitated with an equal volume of ether, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of phenol. On treating about 0.5 Gm. of Salicylic Acid, in a clean test-tube, with 10 Cc. of concentrated sulphuric acid, no color should be imparted to the latter within fifteen minutes (absence of readily carbonizable, organic impurities). A solution of 0.5 Gm. of the Acid in 10 Cc. of alcohol, mixed with a few drops of nitric acid, should remain unaffected upon the addition of a few drops of silver nitrate T.S. (absence of hydrochloric acid).” *U. S.* “Shaken up with a small proportion of water, the mixture filtered, and the solution evaporated, there remains a white residue, having no buff-tinted fringe (absence of iron, organic impurities, and coloring matter). Salicylic Acid dissolves in cold sulphuric acid, imparting to the liquid no color in 15 minutes (absence of organic impurities). When 1 gramme of the Acid is dissolved in an excess of cold solution of sodium carbonate, the liquid agitated with an equal volume of ether, and the ethereal solution allowed to evaporate spontaneously, the residue, if any, should be free from the odor of phenol (absence of phenol).” *Br.* Traces of salol are found in salicylic acid. (Hoffmann, *Proc. A. Ph. A.*, 1896, 232.)

Uses.—Salicylic acid was originally brought to the notice of the profession on account of its inhibitory influence on putrefaction. Kolbe found that 0.04 per cent. had great influence in preventing souring of milk. Bucholz found that 0.15 per cent. of the acid is sufficient to prevent the development of bacteria in ordinary organic mixtures, and that

the influence of 0.005 per cent. is plainly visible; 0.3 to 0.4 per cent. of the acid killed bacteria in vigorous growth. (*A. E. P. P.*, Bd. iv.) Sodium salicylate was about equal to the pure acid, 0.4 per cent. destroying the bacteria. In the preservation of urine, Meyer and Kolbe found that one part of salicylic acid to two thousand of urine was sufficient to prevent putrefaction. (*J. Pr. Chem.*, Bd. xii.) According to Kolbe and others, salicylic acid arrests or prevents the action of the non-organized organic ferments. Thus, it will prevent the development of the hydrocyanic acid by the action of emulsin upon amygdalin in the presence of water, and will also inhibit the formation of the volatile oil of mustard. Miller found that one per cent. of salicylic acid was sufficient to check the action of ptyalin upon starch, thus equalling in power ten per cent. of phenol. He also found that 0.2 per cent. of salicylic acid distinctly affected outside of the body the digestive action of pepsin. The test of clinical experience has shown that salicylic acid is capable of accomplishing much in antiseptic surgery; but, in spite of certain advantages which the remedy has, it has failed to maintain itself against phenol and other antiseptics, so that it is at present but little used by the surgeon. Nevertheless, as it is still employed to some extent, we give the following methods of use.

Thiersch's *salicylic acid wadding* for hermetically sealing wounds is made by dissolving two ounces of the acid in two pints of alcohol (sp. gr. 0.83), diluting with twenty pints of water at from 158° to 178° F., saturating with this six pounds and eight ounces of cotton batting deprived of oily matter, and afterwards drying. This wadding contains 3 per cent. of the acid; for some purposes a stronger batting, containing 10 per cent., is prepared. When the wound or abscess is discharging profusely, jute is substituted for the cotton batting, because it is much more permeable to pus. An efficient ointment may be prepared by dissolving one and a half parts of the acid in two parts of alcohol and adding lard, or advantage may be taken of the solubility of the drug in glycerin. The following solutions are used in St. Bartholomew's Hospital. Sodium phosphate, three parts; salicylic acid one part; water fifty parts.—Salicylic acid one part; olive oil forty-nine parts.—Salicylic acid one part; sodium bicarbonate half part; water one hundred parts.—Salicylic acid ten parts; borax eighteen parts; water one hundred parts. A 25 per cent. solution, which will bear dilution with water or alcohol, may be prepared according to the following formula: Salicylic acid, 120 grains; sodium borate, 60 grains; glycerin, sufficient to make 1 fluidounce; heat gently until dissolved.

When salicylic acid is given to man in doses just sufficient to manifest its presence, symptoms closely resembling those of cinchonism result. These are fulness of the head, with roaring and buzzing in the ears. After larger doses,

to these symptoms are added distress in the head, or positive headache, disturbances of hearing and vision (deafness, amblyopia, partial blindness), and excessive sweating. In some cases there is a decided fall of temperature without alteration of the pulse; but probably more commonly the bodily temperature remains unaltered. The action upon the system of the acid and of its sodium, ammonium, potassium, and methyl (oil of gaultheria) salts appears to be identical, and, as several cases of poisoning with one or other of these agents have occurred, we are able to trace the toxic manifestations. Along with an intensification of the symptoms already mentioned, there are ptosis, deafness, strabismus, mydriasis, disturbance of respiration, excessive restlessness passing into delirium, slow laboring pulse, olive-green urine, and involuntary evacuations. In some cases the temperature has remained about normal, but in others has approached that of collapse. The respiration seems to be characteristic, it being both quickened and deepened, often sighing. Sweating usually is very free, and the urine early becomes albuminous. Various local evidences of vasomotor weakness may supervene, such as rapidly appearing bed sores at points subjected to pressure, and transitory dark-colored maculæ on various parts of the body. In several cases death was probably produced by the acid, although there is scarcely one instance which is beyond doubt. In certain cases the mental disturbance has been strangely prolonged, lasting for eight days. In some instances it is cheerful, in others melancholic in type. It is stated that upon drunkards the acid acts very unfavorably, violent delirium being an early symptom.

Upon the lower mammals salicylic acid acts very much as it does upon man, causing mydriasis, marked disturbance of respiration, great nervous prostration, delirium, dyspnoea, and, if the dose has been large enough, death by respiratory paralysis. Moderate therapeutic doses appear to have no powerful influence upon the circulation, such physiological evidence as we have indicating that they increase arterial pressure somewhat by exciting the vasomotor centre and directly increasing the cardiac force. In overdoses salicylic acid causes fall of the arterial pressure, partly by a direct action upon the heart. Our knowledge of the action of the acid upon the nervous system is very imperfect, but it seems to be a depressant of the motor centres. Moderate doses increase the frequency of the respiration, probably in part by an action upon the peripheral pneumogastrics, but chiefly by a direct influence upon the respiratory centres. Toxic doses paralyze the respiratory centres. The action of salicylic acid upon the temperature of normal man is slight and inconstant, unless toxic doses be given: in fever its antipyretic influence is pronounced, but we have no exact knowledge as to the method of its action. It is absorbed and circulates in the blood probably as sodium sal-

icylate, and is eliminated partly unchanged as a salicylate, and partly as salicyluric acid, the green discoloration of the urine being due to indican, or perhaps to pyrocatechin, which may be an educt from the acid. The elimination both of urea and uric acid is increased by the salicylates, which appear in some way to profoundly affect the general protoplasmic chemical activities. Given in very large doses the salicylates irritate the kidneys.

The first effect of a single antipyretic dose in fever is usually a profuse sweat, which may appear fifteen minutes after the ingestion of the remedy. Very shortly after this the temperature begins to fall, the depression reaching its maximum in from five to six hours. The sweating is profuse and exhausting, amounting, according to Ewald, not rarely to seven hundred and fifty grammes. As a practical antipyretic, however, salicylic acid has been superseded by more convenient remedies. The possession of very marked antiperiodic powers has been claimed for salicylic acid, but experience has not substantiated this claim. In *rheumatism* the remedy is the most valuable one known. Although some cases do not seem to yield to the drug, in the great majority of instances improvement sets in within twenty-four hours, and is rapidly followed by disappearance of the pain and fever. The dangers of cardiac and cerebral complications are certainly lessened, but not altogether done away with. In excessive *rheumatic hyperpyrexia* it cannot be depended upon to the exclusion of the cold bath. In *chronic rheumatism* and in *gout*, indeed in all the various forms of the uric acid diathesis, salicylic acid is an extremely valuable remedy, in many cases bringing relief when all other known remedies fail. To gouty patients it is often administered with great advantage in combination with preparations of colchicum. In all of these cases, however, salicylic acid must be considered as essentially palliative rather than curative. Most of the symptoms of gouty or rheumatic affections are due to an excess of uric acid, locally deposited or circulating in the blood or other fluids of the system. The salicylates bring relief by causing the elimination of this accumulated uric acid, but, so far as we know, they do not in any way affect the fundamental lesions or conditions which cause the excessive production of uric acid. The salts of salicylic acid are so much less irritant than the acid, that the latter is rarely used in practical medicine, but it may be given up to a drachm (3.88 Gm.) in the twenty-four hours, although it is employed by some practitioners in much larger doses. If ringing in the ears or other evidences of intoxication appear, the remedy should at once be partially or entirely withdrawn.

Although Kolbe took fifteen grains of salicylic acid daily for nine months without sensible effect, and Lehmann (*Archiv f. Hygiene*, v.) carried similar experiments even to a greater length with similar results, yet the prac-

tice of using salicylic acid for a preservative of beer and of articles of food is to be condemned. A commission appointed by the French government reported that the prolonged use even of very small amounts of salicylic acid is dangerous, especially to very aged persons. The question of the comparative medicinal value of the artificial and the natural salicylic acid is one of importance. It is seemingly established that the commercial artificial acid is distinctly more poisonous than the natural acid. According to the researches of Dunstan, the poisonous properties of the artificial acid are due to the presence of three impurities,—namely, meta-, ortho-, and para-cresotic acid, of which acids the ortho- and para- are centric poisons. (See PART II.) Salicylic acid produced from synthetic phenol does not contain these poisons. According to the researches of M. Charteris, any artificial salicylic acid which does not closely resemble in crystalline forms the natural acid, and also have a melting point of almost 157° C., should be rejected as probably poisonous.

Dose, five to thirty grains (0.32 to 2.0 Gm.).

ACIDUM STEARICUM. U. S.

STEARIC ACID

(ăç'î-dûm stê-ăr'î-cûm)

$\text{HC}_{18}\text{H}_{35}\text{O}_2 = 282.14$

"A monobasic organic acid [$\text{C}_{17}\text{H}_{35}.\text{COOH}$], in its commercial, more or less impure form, usually obtained from the more solid fats, chiefly tallow." *U. S.*

Acidum Stearinicum; Acide Stéarique, Fr.; *Talg-saure, Stearinsäure, G.*

Preparation.—Stearic acid is obtained from tallow soap by treating it with sulphuric or hydrochloric acid, whereby sodium sulphate or chloride is produced and stearic acid liberated; it is also made on a large scale by purifying the residue left after making glycerin by acting on stearin with superheated steam. (See *Glycerinum*.)

Properties.—It is officially described as "a hard, white, somewhat glossy solid; odorless and tasteless, and permanent in the air. Insoluble in water; soluble in about 16.6 parts of alcohol at 25° C. (77° F.); readily soluble in boiling alcohol, and in ether. Stearic Acid, when pure, melts at 69.2° C. (156.6° F.). The commercial Acid should have a melting point not lower than 56° C. (132.8° F.), and the melted Acid should become opaque and begin to congeal at a temperature not lower than 54° C. (129.2° F.). If 1 Gm. of Stearic Acid and 0.5 Gm. of monohydrated sodium carbonate be boiled with 30 Cc. of water, in a capacious flask, the resulting solution, while hot, should not be more than opalescent (limit of *undecomposed fat*)." *U. S.*

Uses.—This acid was introduced into the U. S. P. of 1890 and 8th Rev. solely because of its use in making glycerin suppositories.

ACIDUM SULPHURICUM. U. S., Br.

SULPHURIC ACID

(ăç'î-dûm sül-phû'rî-cûm)

$\text{H}_2\text{SO}_4 = 97.35$

"A liquid composed of not less than 92.5 percent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $\text{SO}_2(\text{OH})_2 = 97.35$], and about 7.5 percent. of water. It should be kept in glass-stoppered bottles." *U. S.* "An acid produced by the combustion of sulphur or pyrites and the oxidation and hydration of the resulting sulphurous anhydride by means of nitrous and aqueous vapors. It should contain about 98 per cent. by weight of hydrogen sulphate, H_2SO_4 ." *Br.*

Oil of Vitriol, Vitriolic Acid; Hydrogen Sulphate; Acide sulfurique, Huile de Vitriol, Fr.; *Acidum Sulfuricum, P. G.*; *Vitriolöl, Schwefelsäure, G.*; *Acido solforico, It.*; *Acido sulfurico, Sp.*

Preparation.—Sulphuric acid is obtained by burning sulphur or iron pyrites, FeS_2 , and allowing the product of combustion, SO_2 , to mix with nitrous fumes obtained from the decomposition of sodium nitrate, which change SO_2 into SO_3 , and this uniting with steam yields H_2SO_4 . If the sulphur were burned by itself, the product would be sulphurous oxide, which contains only two-thirds as much oxygen as sulphuric oxide. The object of the sodium nitrate is to furnish, by its decomposition, the requisite additional quantity of oxygen. To understand the process, it is necessary to remember that several oxides of nitrogen have oxidizing power. Thus, the main reactions of the sulphuric acid process are

in which the sulphurous oxide from the burning pyrites or sulphur is oxidized to sulphuric oxide by the nitrogen tetroxide, which readily parts with two atoms of oxygen to such bodies as sulphurous oxide, and then takes two atoms of oxygen again from the atmosphere, regenerating the original tetroxide. The nitrogen tetroxide thus acts simply as a carrier of atmospheric oxygen, whereby the SO_2 is changed into SO_3 . This latter compound then unites with steam to form H_2SO_4 , the final product. If the supply of steam be insufficient, white crystals (*lead chamber crystals*) will also form, which have the composition $\text{HSO}_3(\text{NO}_2)$, according to the following reactions:

when steam enters in larger amount they disappear, with formation of sulphuric acid, while red fumes are given off, thus:

Thus, here, nitrous oxide, N_2O_3 , aids oxidation.

Preparation on the Large Scale.—The manufacture of this most important chemical has grown to enormous proportions. In England, where it is very largely manufactured, the production in 1900 amounted to 992,400 tons from pyrites and 100,000 tons from sulphur and gas purifying mixture; in the United States the amount from pyrites and sulphur was 863,282 tons, and from the roasting of zinc blende 75,000 tons; in Germany there were manufactured 878,000 tons; France 492,000 tons; Italy and Austria each 200,000 tons; Belgium 164,000 tons; Russia 125,000 tons; Japan 50,000 tons; and additional amounts not definitely ascertained in Spain and in Scandinavian countries. As made from pyrites, the process is as follows: Beginning with the pyrites-kilns, or burners, the broken mineral is placed in moderate-sized lumps on the bars of the burners, which have previously been heated to redness, and when the burning is once started, the fire is kept up by placing a new charge on the top of that nearly burned out. The ordinary charge for each burner of pyrites, containing about 48 per cent. of sulphur, is from 5 to 6 cwt., which is burnt out in twenty-four hours. The hot sulphur dioxide and air are drawn from the pyrites-burners through the whole system of tubes, towers, and chambers by help of the powerful draught from a large chimney which is placed in connection with the apparatus. These gases then pass either into a tall tower (called the Glover or denitrating tower), where they meet a descending stream of strong sulphuric acid charged with nitrous fumes, which at this moment of descent is mixed with a weaker sulphuric acid, thereby liberating the nitrous fumes which then mix with the sulphur dioxide and air, or they are charged with nitrous fumes direct from the nitre-pots, where a mixture of Chili saltpetre and sulphuric acid liberates them. The mixed gases are then delivered at a temperature of about 75° C. (167° F.) into the first of the leaden chambers. These chambers, of which there are three, are now made of much larger size than was formerly the case, having often a capacity of 38,000 cubic feet. Here the gases meet jets of steam and deposit liquid sulphuric acid, as also in the second chamber. In the third or exhaust chamber all the sulphur dioxide should have been converted into sulphuric acid, and red nitrous fumes must always be visible. These must not be lost, but are drawn into a so-called Gay-Lussac tower filled with coke, over which a finely divided shower of strong acid is allowed to fall. The nitrous fumes are absorbed by this, and give the so-called nitrated acid used as before mentioned in the Glover tower. The acid obtained in the leaden chambers has a sp. gr. of 1.55, or contains 64 per cent. of H_2SO_4 . The acid which comes from the Glover tower (or, in case this is not used, is obtained by further concentration of chamber acid in leaden pans) has a sp. gr. of 1.71, and contains 78 per cent. H_2SO_4 . The strongest acid

must be procured by still further concentration in glass or platinum vessels, and will contain 98 per cent. H_2SO_4 . (Roscoe and Schorlemmer, *Chem.*, vol. i. pp. 321-338.) Within recent years it has been found that to continue the concentration to the limit of 98 per cent. acid in platinum vessels is very destructive to these. Therefore it has been proposed, after a strength of 65° B. or about 90 per cent. acid has been reached, to finish in vessels of cast iron. It is found that the concentrated acid does not attack this, and therefore it can be substituted for platinum to advantage.

According to theory, 100 parts of sulphur burnt should yield 305.9 parts of pure sulphuric acid. In practice the yield is 290 to 294. The amount of sodium nitrate used varies very much. Manufacturers who employ Glover and Gay-Lussac towers require from 3.5 to 6.5 parts of nitrate for every 100 of sulphur burnt, while works unprovided with these appliances may take from 12 to 13 parts. (Roscoe and Schorlemmer, *Chem.*, vol. i. p. 337.)

In 1901, the "Badische Anilin and Soda-fabrik" began on a large scale the manufacture of sulphuric acid by what is known as the "contact process," and since then this process has developed very successfully, and is now in use in this country in a number of the newer chemical works. It is rather a process for the manufacture, on a commercial scale, of sulphur trioxide, which then can be allowed to take up the necessary amount of water to form acid of any strength. A mixture of sulphur dioxide and purified air is passed over heated platinized asbestos, which is the so-called "contact material." To make the process successful, the sulphur dioxide gas must be washed to free it from dust, and all traces of volatile arsenic compounds (arising from arsenical pyrites) must be absent; in addition, the temperature must be regulated with great care to avoid the dissociation of the sulphur trioxide formed. The sulphur trioxide can be marketed as anhydride or as concentrated sulphuric acid of any desired strength.

The only way to obtain pure sulphuric acid from chamber acid is by distillation. Owing to the high boiling point of this acid, the operation is rather precarious, in consequence of the danger of the fracture of the retort from the sudden concussions to which the boiling acid gives rise. Ure recommended that a retort of the capacity of from two to four quarts be used in distilling a pint of acid. This is connected, by means of a wide glass tube three or four feet long with a receiver surrounded with cold water. All the vessels must be perfectly clean, and no luting employed. The retort is then gradually heated by a small furnace of charcoal, or, what is better, by means of a sand bath, the retort being buried in the sand up to the neck. It is useful to put into the retort a few sharp-pointed pieces of glass, slips of platinum foil, or clay tobacco pipe tubes, with the view of diminishing the shocks

produced by the acid vapor. The distilled product ought not to be collected until a dense grayish-white vapor is generated, the appearance of which is a sign that the pure concentrated acid is coming over. If this vapor should not immediately appear, it shows that the acid subjected to distillation is not of full strength; and the distilled product, until this point is attained, will be an acid water. In the distillation of sulphuric acid, Lembert uses, instead of pieces of glass or platinum foil, fragments of the mineral called quartzite; these after a time get worn and must be changed.

What is said above relates to the mode of preparing common sulphuric acid; but there is another kind, known on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen*, so called from its properties, and a place in Saxony where it was first manufactured. This acid is obtained by distilling dried ferrous sulphate in large stoneware retorts, heated to redness, and connected with receivers of glass or stoneware. The fuming acid distils over, and ferric oxide is left in the form of *colcothar* or *polishing rouge*, a material used for polishing metals, particularly gold and silver. The formula usually given for fuming sulphuric acid is $\text{H}_2\text{S}_2\text{O}_7$ or $\text{H}_2\text{SO}_4 + \text{SO}_3$. This would demand about 45 per cent. of sulphuric oxide or SO_3 . In fact, the so-called Nordhausen acid seldom contains more than 10 per cent. of SO_3 , and to obtain that demanded by the formula a re-distillation is necessary. This product is semi-solid, and is now obtainable in commerce put up in sealed glass flasks. Its sale has been largely curtailed lately, owing to the introduction into commerce of the *anhydride* under the name of *Solid Sulphuric Acid*. When moisture is rigidly excluded, the acid has little action on metals, and it is put up in soldered boxes of tinned sheet-iron; it is used largely in the arts in the manufacture of artificial alizarin and indigo. *Persulphuric acid* and the *persulphates* are among recent products of electrolysis. The ammonium persulphate, $(\text{NH}_4)_2\text{S}_2\text{O}_8$, and potassium persulphate, $\text{K}_2\text{S}_2\text{O}_8$, both form white crystalline salts. The former has already found a considerable technical application as an energetic oxidizing agent in the manufacture of organic dyestuffs and the cyanide extraction of gold.

Properties.—Sulphuric acid (*hydrogen sulphate*), commonly called *oil of vitriol*, is a dense, colorless, inodorous liquid, of an oily appearance, and strongly corrosive. On living tissues it acts as a powerful caustic. It unites with water in all proportions, and much heat is evolved on the mixture of the two fluids. When pure and as highly concentrated as possible, as manufactured in leaden chambers, its sp. gr. is 1.840 (1.8485, Ure), a fluidounce weighing a small fraction over 14 drachms. If its density exceed this, the presence of lead sulphate or other impurity may be inferred. Kohlrausch (*Pogg. Ann. Ergänzungs*, Bd. viii. p. 675, Lunge) found the sp. gr. of *pure sul-*

phuric acid, real hydrate, to be 1.8342, and believes that a higher sp. gr. than this is due to impurities (probably lead sulphate). The commercial acid is seldom of this strength. According to Phillips, it has generally the sp. gr. 1.8433, and this is about the strength of the Br. acid, of which the sp. gr. is stated to be 1.843 at 15.6°C . (60°F .). The specific gravity of the U. S. P. (8th Rev.) acid is 1.826 at 25°C . (77°F .); the British acid contains about 98 per cent. of absolute sulphuric acid and the U. S. P. (8th Rev.) acid 92.5 per cent. Mendeleeff, after a careful determination, found that pure monohydrated sulphuric acid had the specific gravity 1.8371 at 15°C . (59°F .) compared with water at its maximum density, 4°C . (*Am. Drug.*, 1885, p. 16.) The strong acid boils at 338°C . (640.4°F .), and freezes at -26°C . (-15°F .). When diluted, its boiling point is lowered. When of the sp. gr. 1.78, it deposits crystals of the formula $\text{H}_2\text{SO}_4 + \text{H}_2\text{O}$ at about 0°C . (32°F .), and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases it forms a numerous class of salts, called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, developing charcoal, and turning them black. A small piece of cork or wood dropped into the acid will for this reason render it of a dark color. It absorbs water with avidity, and is used as a desiccating agent. It has been ascertained by W. B. and R. E. Rogers to be capable of absorbing 94 per cent. of carbon dioxide, a fact having an important bearing on analytical operations. When diluted with distilled water, it ought to remain limpid; and, when heated sufficiently in a platinum spoon, the fixed residue should not exceed one part in 400 of the acid employed. When present in small quantity in solution, it is detected unerringly by barium chloride, which causes a precipitate of barium sulphate. The most usual impurities in it are arsenic compounds and lead sulphate; the former derived from the presence of arsenides in the pyrites, where that has been used in the production of the sulphurous oxide, the latter from the leaden boilers in which the acid is concentrated. Sodium or magnesium sulphate is said to have been added to increase its specific gravity. "Miscible, in all proportions, with water or alcohol, with evolution of much heat; the Acid should be added with great caution to the diluent. It boils at 338°C . (640.4°F .). When heated on platinum foil, it is vaporized, with the evolution of dense fumes, without leaving a residue. Sulphuric Acid, even when highly diluted, shows an acid reaction upon blue litmus paper. If Sulphuric Acid be dropped upon cane-sugar or wood, it chars them. Diluted with 20 volumes of water, it yields with barium chloride T.S. a copious white precipitate, insoluble in hydrochloric acid." U. S.

Occasionally potassium nitrate is added to render dark samples of acid colorless. This addition gives rise to the impurity of potassium sulphate. These impurities often amount to 3 or 4 per cent. The commercial acid cannot be expected to be absolutely pure; but when properly manufactured it should not contain more than one-fourth of 1 per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the acid, when they will remain. If lead sulphate be present, the acid will become turbid on dilution with an equal bulk of water. This impurity is not detected by hydrogen sulphide unless the sulphuric acid be saturated with an alkali. If only a scanty white turbidity arise, the acid is of good commercial quality.

Other impurities occur in the commercial sulphuric acid. The several oxides of nitrogen are always present in greater or less amount in lead chamber acid. They may be detected by gently pouring a solution of ferrous sulphate over the commercial acid in a tube, when the solution, at the line of contact, will acquire a deep red color, due to the liberation of nitrogen tetroxide. Another method is to pass into tincture of guaiac the gases proceeding from the suspected acid heated with iron filings. If nitrogen tetroxide be present, the tincture becomes blue. The commercial acid, however, is not to be rejected unless the test shows the presence of nitrogen tetroxide in unusual quantity. Nitrogen tetroxide is an injurious impurity when the sulphuric acid is employed in the manufacture of hydrochloric acid, which is decomposed by the nitrogen tetroxide with evolution of chlorine. To remove this impurity it was recommended by Wackenroder, before distilling it, to heat the acid with a little sugar. This and the N_2O_4 mutually decompose each other, and the products are dissipated by heat. For the removal of the nitrogen acids generally, J. Löwe recommends the addition to the heated sulphuric acid of small portions of dry oxalic acid, so long as it exhibits a yellow tinge. The oxalic acid is decomposed into carbon dioxide and oxide, the latter of which, in becoming carbon dioxide, deoxidizes and destroys the nitrogen acids. A slight excess of oxalic acid produces no harm, as it is immediately decomposed. Perhaps a better method of getting rid of these acids is to distil with a little ammonium sulphate. Potassium sulphate, fraudulently introduced into the acid to increase its density, may be detected by saturating the acid with ammonia and heating to redness in a crucible, when ammonium sulphate will be expelled, and the potassium sulphate left.

Arsenic is sometimes present in sulphuric acid. In consequence of the high price of Sicilian sulphur, most English manufacturers have employed iron pyrites for the purpose of furnishing the necessary sulphurous acid in the manufacture of oil of vitriol. As the pyrites usually contains arsenic, it happens that the sulphurous acid fumes are accompanied by

arsenous oxide, and thus the sulphuric acid becomes contaminated. From 22 to 35 grains of arsenic trioxide have been found in 20 fluid-ounces of oil of vitriol, of English manufacture, by G. O. Rees and Watson, and a still larger proportion by J. Cameron of South Wales. To detect this impurity, the acid, previously diluted with five or six measures of distilled water, must be examined by Marsh's test. (See *Arseni Trioxidum*.) But an easier method, said to be nearly as delicate, is that of Bettendorf. A little stannous chloride is treated, in a shallow dish, with pure hydrochloric acid (sp. gr. 1.12) until dissolved. The suspected sulphuric acid is then added, drop by drop, to the solution, the vessel being shaken on each addition. Considerable heat will be produced, and the liquid, if no arsenic be present, will remain clear; but if the acid be in the slightest degree contaminated with the poison, first a yellow, then a brown, and finally a dark grayish brown color will appear, and the liquid become turbid. (*N. R.*, April, 1873, p. 367.) To separate the arsenic trioxide, J. Löwe recommends that the concentrated sulphuric acid should be gently heated in a flat dish, in a place where the fumes may be carried off, and then treated with small quantities of finely powdered sodium chloride, constantly stirred in with a glass rod. By the reaction between the arsenic trioxide and disengaged hydrochloric acid arsenic trichloride is formed, which, being volatile, is separated by the heat. The heat is afterwards continued, to expel the excess of hydrochloric acid. This mode of purification introduced into the oil of vitriol a little sodium sulphate. Buchner proposes a similar process; instead of sodium chloride, employing hydrochloric acid, or a stream of the acid gas. This plan does not introduce sodium sulphate into the acid, but is less convenient than that of Löwe, and, when the aqueous hydrochloric acid is used, tends to weaken the oil of vitriol by introducing water. Experience, however, has shown that neither plan can be entirely relied on. An excess of sulphuric acid is said to prevent the formation of the arsenic chloride. (See *A. J. P.*, 1860, p. 88.) For other methods of detecting arsenic in sulphuric acid, see *N. R.*, 1876, p. 297; 1880, p. 101. Denigès proposes to detect arsenic in sulphuric acid by the use of a liquid containing equal volumes of a solution of ammonium molybdate (1 to 10) and sulphuric acid. (*D. C.*, 1894, 12.) Until within recent years all the sulphuric acid produced in the United States was made from sulphur. At the present time many of the sulphuric acid works are using pyrites. Most of the American pyrites ore is entirely free from arsenic. Dupasquier states that tin is sometimes present in commercial sulphuric acid, derived from the solderings of the leaden chambers; but this could scarcely happen now, as care is taken to avoid soldering, and to effect the union of the metal by fusion by means of the blow-pipe. It may

Table of Percentage and Specific Gravity of Sulphuric Acid. U. S. P. (8th Rev.)

¹ Add if the temperature is above, subtract if below, 25° C.

² Corresponding with a difference in specific gravity of 0.0001.

³ Note that the specific gravity diminishes in acids of more than 97.5 per cent. strength as the percentage increases.

NOTE.—To find the per cent. of SO₃, multiply the per cent. of H₂SO₄ by 0.81633; to find the per cent. of SO₄, multiply the per cent. of H₂SO₄ by 0.97946.

To find the weight in grammes of H₂SO₄ in 100 Cc., multiply the specific gravity by the per cent. of H₂SO₄.

To find the volume per cent. of official Sulphuric Acid, multiply the "normality" by 2.891. For the volume per cent. of official Diluted Sulphuric Acid, multiply the "normality" by 45.76.

be discovered by hydrogen sulphide, which precipitates sulphide of tin, convertible by nitric acid into the white insoluble stannic oxide. Should the precipitate be the mixed sulphides of arsenic and tin, the former would be converted by nitric acid into arsenic acid and dissolved, and the latter into insoluble stannic oxide and left. Another impurity occasionally existing in French sulphuric acid is selenium, supposed to be derived from copper pyrites sometimes substituted for sulphur in the manufacture of the acid.

Tests.—"On mixing the Acid carefully with 4 or 5 volumes of alcohol, no precipitate should be formed within one hour (absence of *lead*). If there be carefully poured upon it, in a test-tube, a layer of ferrous sulphate T.S., and the liquid cooled, the zone of contact should not assume a brown or reddish color (limit of *nitric* or *nitrous acid*). Sulphuric Acid, diluted with 20 volumes of water, should yield no precipitate upon the addition of silver nitrate T.S. (absence of *hydrochloric acid*); nor should the solution respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121); nor, upon supersaturating with ammonia water, should the solution leave any appreciable fixed residue on evaporation and ignition (absence of *non-volatile impurities*). One Cc. of Sulphuric Acid, diluted with 5 Cc. of water and cooled, should not at once discharge the color of 0.1 Cc. of tenth-normal potassium permanganate V.S. (limit of *sulphurous* or *nitrous acid*). If Sulphuric Acid be diluted with water (1 in 10), 5 Cc. should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17).

If 2 Cc. of hydrochloric acid in which a fragment of sodium sulphite has been dissolved be carefully poured upon 2 Cc. of Sulphuric Acid contained in a test-tube, the zone of contact should not assume a pink or red color upon standing, nor should a precipitate form after heating (limit of *selenium*). Introduce into a stoppered weighing-bottle 3 Cc. of Sulphuric Acid and weigh accurately. Dilute the acid with 50 Cc. of distilled water and titrate with normal potassium hydroxide V.S., using methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal potassium hydroxide V.S. consumed, by 4.8675, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Sulphuric Acid in the latter." *U. S.* "Each gramme diluted with 20 or 30 cubic centimetres of *water* should require for neutralization 20.1 cubic centimetres of the *volumetric solution of sodium hydroxide*. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, ammonium, chlorides, nitrates, nitrites, or sulphites. It should yield no appreciable residue on evaporation. *Hydrochloric acid* containing *sodium sulphite*, when poured carefully upon an equal volume of Sulphuric Acid contained in a test-tube, should not cause a red coloration at the junction of the

two liquids, and no red precipitate should form on warming the tube (absence of *selenium*)." *Br.*

The table (pages 72 and 73) from the *U. S. P.* (8th Rev.) shows the percentage and specific gravity of sulphuric acid of various strengths.

Composition.—The normal acid of the sp. gr. 1.842 consists of one molecule of oxide and one molecule of water. As the hydrogen acts the part of a metal in the compound, the systematic name would be hydrogen sulphate. The oxide consists of one atom of sulphur and three atoms of oxygen. The ordinary commercial acid consists, according to Phillips, of one molecule of oxide and one and a quarter molecules of water. The hydrated acid of Nordhausen has a density as high as 1.89 or 1.9, and consists of two molecules of oxide and one molecule of water ($2\text{SO}_3 + \text{H}_2\text{O}$). This acid is particularly adapted to the purpose of dissolving indigo for dyeing the Saxon blue. When heated gently in a retort, connected with a dry and refrigerated receiver, sulphuric oxide or anhydride distils over, and the common monohydrated acid remains behind. In performing this operation, much difficulty from concussion is avoided, and the product of oxide increased, by introducing a coil of platinum wire into the retort. The oxide may also be obtained by the action of phosphoric oxide on concentrated sulphuric acid, according to the method of Barreswil. The mixture must be made in a refrigerated retort, and afterwards distilled by a gentle heat into a refrigerated receiver. *Sulphuric oxide (solid sulphuric acid)* under 18°C . (64°F .) is in small colorless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapor of an acid odor. Above 18°C . (64°F .) it is a liquid, very nearly of the density 2.

Uses.—For the therapeutic powers and uses of sulphuric acid when administered internally, see *Acidum Sulphuricum Dilutum*. Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for that purpose, and should be applied with caution. A plan, however, has been proposed by Simpson by which it becomes very manageable. This consists in mixing it with dried and powdered zinc sulphate sufficient to give it a pasty consistence. *Michel's Paste* consists of strong sulphuric acid three parts, and finely powdered asbestos one part, thoroughly rubbed together. Mixed with saffron to the consistence of a ductile paste, Velpeau found it a convenient caustic not liable to spread or be absorbed, and producing an eschar which is promptly detached.

Toxicological Properties.—The symptoms of poisoning by this acid are the following: Burning heat in the throat and stomach, extreme fetidness of the breath, nausea and excessive vomitings of black or reddish matter, excruciating pains in the bowels, difficulty of breathing, extreme anguish, a feeling of cold

on the skin, great prostration, constant tossing, convulsions, and death. Sometimes there is no pain whatever in the stomach, sensibility being apparently destroyed by the violence of the caustic action. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or, if this be not at hand, of solution of soap. The safety of the patient depends upon the greatest promptitude in the application of the antidotes. After the poison has been neutralized mucilaginous and other bland drinks must be taken freely.

Upon the skin sulphuric acid acts as a very rapid and powerful corrosive. When it has been spilled or thrown upon the person the part should be immediately washed with a weak solution of sodium carbonate or bicarbonate, or soap may be well rubbed into the surface. After the removal and neutralization of the acid, Carron oil or similar protective may be applied. Further treatment is that of a burn.

The holes burnt in linen by sulphuric acid, so long as the texture is undisturbed, are distinguished from those produced by red-hot coals, by the paste-like characters of their edges.

Uses in the Arts.—Sulphuric acid is more used in the arts than any other acid. It is employed to obtain many of the other acids; to extract soda from common salt; to make alum and ferric sulphate; to refine petroleum and paraffin; to decompose the neutral fats; to dissolve indigo; to prepare phosphorus, chlorinated lime, magnesium sulphate, etc. Petroleum refining and manufacture of fertilizers from phosphatic materials consume the largest amounts of sulphuric acid in the United States.

AROMATIC SULPHURIC ACID

(äc'ŭ-düm sŭl-phŭ'rŭ-cŭm ä'r-ŭ-mät'ŭ-cŭm)

"Aromatic Sulphuric Acid should contain not less than 20 per cent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $\text{SO}_2(\text{OH})_2 = 97.35$], partly in the form of ethyl-sulphuric acid." *U. S.*

Tinctura Aromatica Acida; Elixir of Vitriol; Elixir vitriolique, Teinture (alcoolé) aromatique sulphurique, *Fr.*; Saure Aromatische Tinctur, Elixir Vitrioli Mynsichti, Mynsicht's Elixir, *G.*

* "Sulphuric Acid, one hundred and eleven cubic centimeters [or 3 fluidounces, 6 fluidrachms, 1 minim]; Tincture of Ginger, fifty cubic centimeters [or 1 fluidounce, 5½ fluidrachms]; Oil of Cinnamon, one cubic centimeter [or 16 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms].

Add the Sulphuric Acid gradually, and with great caution, to seven hundred cubic centimeters [or 24 fluidounces] of Alcohol, and allow the mixture to cool. Then add to it the Tincture of Ginger and the Oil of Cinnamon, and afterwards enough Alcohol to make the whole measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Keep the product in glass-stoppered bottles." *U. S.*

"Tincture of Ginger, 10 fl. ounces (Imperial measure) or 250 cubic centimeters; Spirit of Cinnamon, ½ fl. ounce (Imp. meas.) or 12.5 cubic centimeters; Alcohol (90 per cent.), 29½ fl. ounces (Imp. meas.) or 737.5 cubic centimeters; Sulphuric Acid, 3 fl. ounces (Imp. meas.) or 2419 grains, or 75 cubic centimeters or 138.2 grammes. Mix the Sulphuric Acid gradually with the Alcohol; add the Spirit of Cinnamon and Tincture of Ginger." *Br.*

The formula adopted at the 1880 revision of the *U. S. Pharmacopœia* and continued in the 1890 and 8th Revision is that recommended by Thomas N. Jamieson, *A. J. P.*, 1867, p. 201. The change in the appearance and properties from the preparation of the *U. S. P.* 1870 was so marked that the wisdom of making so radical a change was doubted. Experience has proved, however, that the new preparation has not the same tendency to precipitate, and the lightness in color has been offset by more substantial advantages. The British formula has been remodelled to accord with the *U. S. P.* The proportion of sulphuric acid was increased in the *U. S. P.* (8th Rev.) about 10 per cent. over that of the previous *Pharmacopœia*.

Properties.—Aromatic sulphuric acid of the older *Pharmacopœias* was of a deep reddish brown, but it is a straw-colored liquid when freshly prepared according to the directions of the *U. S. Pharmacopœia* (8th Rev.), of a peculiar aromatic odor, and, when sufficiently diluted, of a grateful acid taste. It has been supposed by some to contain ethylic ether or sulphovinic acid, its main ingredients justifying such a suspicion; but Duncan of Edinburgh, who originally held this opinion, satisfied himself that the alcohol and sulphuric acid, in the proportions here employed, do not generate a single particle of ethylic ether; and Attfield has shown that there is no ethyl-sulphuric acid in the official preparation. (*P. J.*, 1869, p. 471.) It cannot, however, be viewed merely as a sulphuric acid diluted with alcohol and containing essential oils, for the difference between fresh and old preparations is quite marked, and a peculiar and agreeable ethereal odor is developed by age. The *U. S.* official definition recognizes the presence of ethyl sulphuric acid.

"Specific gravity: about 0.933 at 25° C. (77° F.). If 10 Gm. of Aromatic Sulphuric Acid be

mixed in a small flask with 30 Cc. of water and be boiled for several minutes, cooled and diluted with water to measure 100 Cc., then 48.68 Cc. of this solution, to which exactly 25 Cc. of normal potassium hydroxide V.S. have been added, should require not more than 5 Cc. of normal sulphuric acid V.S. for complete neutralization (each Cc. of the normal potassium hydroxide V.S. consumed corresponding to 1 percent. of absolute Sulphuric Acid), methyl-orange T.S. being used as indicator." *U. S.*

The sp. gr. of the British preparation is "0.922 to 0.926. The neutralizing power of 100 grammes should be equivalent to that of 13.8 grammes of hydrogen sulphate, H_2SO_4 ." *Br.*

Samples of fresh aromatic sulphuric acid as well as older specimens have been assayed by E. W. Clark, and all were found to be more or less deficient in sulphuric acid; the inference is quite clear that there is some decomposition of sulphuric acid in the preparation upon keeping. (*Ph. Era*, 1887, p. 69.)

Uses.—This valuable preparation is tonic and astringent. It acts precisely as does the *Acidum Sulphuricum Dilutum*.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.), in a wineglassful of water, repeated two or three times a day. Care must be taken that the teeth are not injured.

Off. Prep.—Infusum Cinchonæ Acidum, *Br.*

ACIDUM SULPHURICUM DILUTUM.

U. S., *Br.*

DILUTED SULPHURIC ACID

(ăc'i-dūm sūl-phŭ'rī-cūm dī-lŭ'tūm)

"Diluted Sulphuric Acid should contain not less than 10 percent., by weight, of absolute Sulphuric Acid [H_2SO_4 or $\text{SO}_2(\text{OH})_2=97.35$], and about 90 percent. of water." *U. S.* "100 parts by weight should contain 13.65 parts of hydrogen sulphate, H_2SO_4 ." *Br.*

Acide sulphurique diluée, *Fr.*; Acidum sulphuricum dilutum, *P. G.*; Verdünnte Schwefelsäure, *G.*

* "Sulphuric Acid, one hundred grammes [or 3 ounces av., 231 grains]; Distilled Water, eight hundred and twenty-five grammes [or 29 ounces av., 44 grains], to make nine hundred and twenty-five grammes [or 32 ounces av., 274 grains]. Pour the Acid gradually, with constant stirring, into the Distilled Water. Keep the product in glass-stoppered bottles. Specific gravity: about 1.067 at 25° C. (77° F.). It should respond to the reactions and tests given under *Acidum Sulphuricum*. To neutralize 4.868 Gm. of Diluted Sulphuric Acid not less than 10 Cc. of normal potassium hydroxide V.S. should be required (each Cc. corresponding to 1 percent. of absolute Sulphuric Acid), methyl-orange T.S. being used as indicator." *U. S.*

"Sulphuric Acid, 1 fl. ounce and 5½ fl. drachms (more exactly, 1.65 fl. ounces, Imperial measure) or 1333 grains, or 82.7 cubic centimetres or 152.4 grammes; Distilled Water, a

sufficient quantity. Half fill with Distilled Water a glass flask the capacity of which to a mark on the neck is one pint (Imp. meas.) or one thousand cubic centimetres. Then introduce the Sulphuric Acid, and add very gradually Distilled Water until the mixture, after it has been shaken and cooled to 60° F. (15.5° C.), measures one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation is sulphuric acid diluted to such an extent as to make it convenient for prescription. It is not exactly coincident in strength as directed in the two Pharmacopœias, the *U. S.* acid (sp. gr. 1.067) being weaker than the British (sp. gr. 1.094), but slightly stronger than that formerly official; but the difference is not so great as to be of practical importance. The British Pharmacopœia requires that "each gramme should require for neutralization 2.8 cubic centimetres of the volumetric solution of sodium hydroxide." *Br.* The strong acid is added gradually to the water, to guard against the too sudden production of heat, which might cause the fracture of the vessel. During the dilution, when commercial sulphuric acid is used, the liquid becomes slightly turbid, and in the course of a few days deposits a grayish-white powder, which is lead sulphate, and from which the diluted acid should be poured off. This noxious salt is thus disposed of; but potassium sulphate, another impurity in the strong acid, still remains. The presence of a little potassium sulphate will do no harm; but, if it should be fraudulently introduced into the strong acid to increase its specific gravity, its amount may be ascertained by saturating the acid, after dilution, with ammonia, and expelling by a red heat the ammonium sulphate formed. Whatever potassium sulphate is present will remain behind. If the directions of the Pharmacopœias are strictly carried out, and the kind of sulphuric acid is used which is known in commerce as chemically pure, responding to the tests given under the head of *Acidum Sulphuricum*, the official manipulations will be all-sufficient.

Uses.—Diluted sulphuric acid is tonic, refrigerant, and astringent. It is given in typhoid fever, and often with advantage. In the convalescence from protracted fevers it acts beneficially as a tonic, exciting the appetite and promoting digestion. As an astringent, it is employed in colliquative sweats, passive hemorrhages, and diarrhœas dependent on a relaxed state of the mucous membrane of the intestines, i.e., in serous diarrhœas. In 1851, Buxton of London, called attention to its great value in choleraic diarrhœas; his assertions have received abundant confirmation both in this country and in England. (See *M. T. G.*, Oct. 1853; *M. S. Rep.*, ix. 199; *P. M. T.*, iii. 649.) In incipient cholera it is an efficient remedy; diluted with water, it may be given every twenty minutes in ordinary cases, every quarter of an hour in severe cases. For bilious diarrhœa the acid is not a suitable remedy. In calculous af-

fections attended with *phosphatic sediments* it is the proper remedy, being preferable to hydrochloric acid, as less liable to disorder the stomach by continued use. It is added with advantage to infusions of cinchona, the alkaloids of which it tends to hold in solution. As it is injurious to the teeth, it is best taken by sucking it through a glass tube or quill. It is much less used in the United States than is the elixir of vitriol. An elegant form for its administration is the Compound Infusion of Rose, *U. S.* 1870.

Dose, ten to thirty minims (0.6 to 1.8 Cc.).

ACIDUM SULPHUROSUM. *U. S.*, *Br.*

SULPHUROUS ACID

(äç'î-düm sül-phû-rô'süm)

"An aqueous solution containing not less than 6 percent., by weight, of sulphur dioxide [$\text{SO}_2 = 63.59$], and about 94 percent. of water." *U. S.* "An aqueous solution containing 6.4 per cent. of hydrogen sulphite, H_2SO_3 , corresponding to 5 per cent. by weight of sulphurous anhydride, SO_2 . The sulphurous anhydride may be prepared by burning sulphur in air or oxygen, or by boiling sulphuric acid with carbon, mercury, or copper." *Br.*

Acide sulfureux, *Fr.*; Schwefligsaure, Schwefligsaurewasser, *G.*

* "Sulphuric Acid, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Charcoal, in coarse powder, *twenty grammes* [or 309 grains]; Distilled Water, *five hundred cubic centimeters* [or 16½ fluidounces]. Introduce the Charcoal into a glass flask having a capacity of about five hundred cubic centimeters, add the Acid, and mix them well. Connect the flask by means of bent glass tubing, about fifty centimeters in length, with a wash-bottle having a capacity of about two hundred cubic centimeters, containing about *fifty cubic centimeters* [or 1 fluidounce, 5 fluidrachms] of water, so that the end of the inlet tube shall be below the surface of the water. Through the triply perforated rubber stopper of the wash-bottle pass a safety tube, which should reach nearly to the bottom of the bottle, and connect the latter, by means of glass tubing, with a bottle provided with a doubly perforated rubber stopper, having a capacity of about one thousand cubic centimeters, and containing *five hundred cubic centimeters* [or 16½ fluidounces] of well-cooled Distilled Water. The inlet tube should dip about twenty-five millimeters below the surface of the Distilled Water. By means of a second tube connect this bottle with another containing water, the end of the tube extending five centimeters below the surface. Having ascertained that all the connections are air-tight, apply a moderate heat to the flask containing the Sulphuric Acid

and Charcoal, until the evolution of gas has nearly ceased, and, during the passage of the gas, keep the bottle containing the Distilled Water at or below 10° C. (50° F.), by surrounding it with cold water or ice. Assay a small portion of the Sulphurous Acid by the method given below. Then add to the remainder sufficient Distilled Water to bring the product to the strength of 6.4 percent., by weight, of sulphur dioxide. Finally pour the Sulphurous Acid into dark amber-colored, glass-stoppered bottles, which should be completely filled, and kept in a cool place, protected from light. Owing to its rapid deterioration, Sulphurous Acid should be frequently assayed, and none should be dispensed, if it fails to conform to the assay given below." *U. S.*

The British Pharmacopœia no longer gives a detailed process. The process of the *U. S. Pharmacopœia* is essentially that of Wittstein. The sp. gr. of the *U. S.* preparation is about 1.028, of the British, 1.025, the former being slightly stronger.

The rationale of the process is simple. When the sulphuric acid (H_2SO_4) and charcoal are heated together, two molecules of the former give up each an atom of oxygen to the latter, and there are thus produced sulphur dioxide and carbon dioxide, which, having been first passed through a wash bottle containing a little water to absorb impurities, are received into the distilled water, where the sulphur dioxide is absorbed, while the greater part of the carbon dioxide escapes:

The excess of sulphur dioxide or sulphurous acid gas which escapes absorption may be received into a solution of sodium carbonate, to prevent the escape of gas into the room. The point of saturation may be roughly indicated by the bubbles formed by the escape of the gas from the distilled water being equal in size to those formed in the wash bottle. If there is any difficulty in getting the solution up to the official strength, the proportionate amount of sulphuric acid and of charcoal should be increased, and care exercised that the gas pass through the water in an abundant stream. The direction to keep the acid in well stoppered bottles, in a cool place, is necessary in consequence of the strong tendency of the gas to escape and to undergo oxidation. Old sulphurous acid often contains sulphuric acid, which may be nearly all removed by the cautious addition of barium sulphite and the removal by filtration of the precipitated sulphate.

According to W. L. Scott (*P. J.*, Oct. 1869, p. 217), the best results are obtained when sulphuric acid containing 75 per cent. of anhydrous acid is employed; when a too concentrated acid is used, a part of it is entirely reduced and sulphur deposited, while a too diluted acid causes the evolution of hydrogen sulphide. He also affirms that a purer gas is obtained by placing a little lead sulphite and a few pieces of charcoal in the wash bottles.

F. C. Calvert gives a process for preparing this acid on a large scale by which he avoids all the inconveniences usually attendant on its manufacture, and has prepared thousands of gallons daily of a saturated solution. It consists in burning sulphur in a small furnace, and conducting the acid gas through earthenware tubes surrounded with water so as to cool them. The gas is then made to ascend through a wooden tube 40 feet high and about 4 feet wide, sometimes called a coke scrubber, filled with pumice stone previously washed first with hydrochloric acid and then with water. A certain amount of water is introduced into the tube from above, which, in its descent, meets and dissolves the gas, and runs out saturated from the bottom of the tube into an air tight reservoir. (*P. J.*, xvii. 512.) Where sulphurous acid is to be used as a disinfectant, carbon disulphide, either pure or mixed with petroleum, or sulphur moistened with wood alcohol, may be burned in the room to be disinfected. Keates (*Chem. News*, Dec. 8, 1876) suggests the use of a suitable lamp. Stevenson uses an open copper dish or porcelain capsule, and simply ignites the liquid; care should be used, however, as the disulphide is very inflammable and volatile. A purer sulphurous acid than the official may be made by John Kennedy's process, that of reducing sulphuric acid with metallic copper and passing the gas through a cylinder containing lumps of moist charcoal and then through a wash bottle. The by-product is available as copper sulphate. (*A. J. P.*, 1886, p. 226.)

Properties.—The official sulphurous acid is a strong solution of sulphurous oxide gas. The oxide is an irrespirable gas, of a suffocating odor familiar to every one as that of burning sulphur, which is converted into it by combustion. If inhaled in the concentrated state, it proves fatal. Cold reduces it to a colorless liquid, which boils at -10.5° C. (13.1° F.). It has the sp. gr. 2.21, liquefies at -10° C. (14° F.), has a strong acid reaction, extinguishes burning bodies, has the power of bleaching many colored substances, and has a strong affinity for oxygen, with which it combines in the presence of water, forming sulphuric acid. Water at 18° C. (65° F.) takes up about 50 volumes of gas, and the solution has the sp. gr. 1.04. (Brande and Taylor.) Liquefied sulphurous acid gas (oxide) is now manufactured by Pictet in Geneva, and is sent into commerce in copper cylinders. It also forms the basis of the Pictet ice making process. The Pictet machines are constructed to use either the pure SO_2 or the "Pictet fluid," a mixture of compressed carbon dioxide and sulphur dioxide.

Sulphurous acid sometimes exists as an impurity in hydrochloric, acetic, and other acids; according to P. Schweitzer, the minutest quantity may be detected by dissolving zinc in the suspected acid, when, if sulphurous acid be present, hydrogen sulphide will be evolved, recognizable by its odor. (*Chem. News*, xxviii. 293.)

When sulphurous acid is exposed to the air it slowly absorbs oxygen, with the formation of sulphuric acid, and acquires a sour taste, and the property of changing vegetable blues to red. When kept in closed vessels exposed to the sunlight, a portion of it is decomposed, sulphur being deposited and sulphuric acid formed by the union of the liberated oxygen with other portions of the acid. (*A. J. P.*, xlii. 352.) It should be entirely volatilized by heat. It decolorizes iodine by producing hydriodic acid, and on this fact is based the Br. test given below. It decomposes bone calcium phosphate.

"A colorless liquid, having the characteristic odor of burning sulphur, and an acid, sulphurous taste. Specific gravity: not less than 1.028 at 25° C. (77° F.). By heat it is completely volatilized. Blue litmus paper moistened with the Acid is first reddened and afterwards bleached. On gently heating a few Cc. of the Acid in a test-tube, the gas evolved will blacken a strip of paper moistened with mercurous nitrate T.S., but will not affect one moistened with lead acetate T.S. On mixing, in a test-tube, 1 Cc. of Sulphurous Acid with 5 Cc. of diluted hydrochloric acid, and adding a small piece of pure zinc, hydrogen sulphide gas will be evolved, which will blacken a strip of paper moistened with lead acetate T.S. If to 10 Cc. of Sulphurous Acid there be added 1 Cc. of diluted hydrochloric acid, and afterwards 1 Cc. of barium chloride T.S., not more than a slight turbidity should be at once produced (limit of sulphuric acid)." *U. S.*

Assay of Sulphurous Acid.—"Introduce into a stoppered weighing-bottle 2 Cc. of Sulphurous Acid and weigh accurately. To this add 50 Cc. of tenth-normal iodine V.S., and allow it to stand for five minutes, then slowly add tenth-normal sodium thiosulphate V.S. until the mixture is just decolorized. Subtract the number of cubic centimeters of the tenth-normal sodium thiosulphate V.S. used, from 50, and multiply the difference by 0.318, and divide this product by the weight of the Acid taken; the quotient represents the percentage of absolute Sulphurous Acid in the latter. Dilute the Sulphurous Acid with distilled water, as directed in the process above, so that it shall have the strength of 6.4 per cent. of sulphur dioxide." *U. S.* "It gives but a slight precipitate with solution of barium chloride (absence of excess of sulphates), but a copious precipitate if solution of chlorine also be added. When evaporated it leaves no residue. Specific gravity 1.025. Mixed with 100 times its volume of recently boiled and cooled water, and a little mucilage of starch, it should not acquire a permanent blue color with the volumetric solution of iodine until, for each gramme of the acid, 15.7 cubic centimetres of the volumetric solution of iodine have been added." *Br.*

Uses.—Sulphurous acid is a powerful antiseptic and germicide, arresting putrefaction and other fermentations by killing the organisms which produce them. It is supposed to be thus

destructive by its anti-oxygenizing or reducing influence, suffocating organic beings by denying them the oxygen necessary to their existence; but it probably acts also by a physiological property independently of its mere chemical effect. Sulphurous acid and sulphites are widely used for preserving food, especially dried fruits. So-called "sulphite powders" containing either sodium sulphite or calcium or magnesium bisulphites have figured largely in pure food prosecutions, as being used to brighten the color of chopped meat in "Hamburg steaks." According to the experiments of L. Pfeiffer (*A. E. P. P.*, xxvii.), the sulphites are capable of causing death by paralyzing the heart and also the respiratory and other motor nerve centres, but are so rapidly and completely changed into the sulphates that unless given in enormous amount they exert very little influence upon the system; 96.5 per cent. of the sulphite was regained from the urine as a sulphate, and 86 per cent. passed out in five hours after ingestion. Although Robert Bird affirms that sulphurous acid and its salts are powerful antipyretics (*Am. J. M. S.*, lviii. 236), and the acid in the form of the fumes of burning sulphur has been used by inhalation in *low fevers, diphtheria, and whooping cough* with alleged advantage, yet the sulphites are at present employed in medicine almost solely as germicides and parasiticides. In *pyrosis* and in cases of *sarcina ventriculi* sulphurous acid may be taken internally; but one of the sulphites, as sodium sulphite, is perhaps preferable for the purpose, as it yields the acid always by decomposition in the stomach. As an external application, it is used in *psora*, the different forms of *porrigo*, *trichosis of the scalp*, *pityriasis versicolor*, and the *thrush* of children, all *parasitic affections*, either animalcular or cryptogamous, generally yielding to it, if proper care be taken, by previous removal of scabs or scales, to bring it into contact with the morbid cause. When locally used it should be diluted with two or three measures of water or of glycerin, and applied as a lotion, or by cloths wet with it. Sulphurous acid constitutes the active principle of burning sulphur fumes, used for disinfecting purposes.

Dose, for internal use, half to one fluidrachm (1.8 to 3.75 Cc.), well diluted.

ACIDUM TANNICUM. U. S., Br.

TANNIC ACID [Gallotannic Acid]

(ăc'î-dũm tân'nî-cũm)

$\text{HC}_{14}\text{H}_9\text{O}_9 = 319.66$

"A monobasic organic acid [$\text{C}_{14}\text{H}_9\text{O}_7\text{COOH}$], obtained from nutgall." *U. S.* "Tannic acid, $\text{C}_{14}\text{H}_9\text{O}_9, 2\text{H}_2\text{O}$, may be extracted by water-saturated ether from Galls which have been subjected to a special fermentation." *Br.*

Tannin, Digallic Acid, Acidum Gallo-tannicum, Tanninum; Acide tannique, Tannin officinal, *Fr.* *Ood.*; Acidum tannicum, *P. G.*; Gerbsaure, Gallusgerbsaure, Tannin, *G.*; Acido tannico, *It.*; Acido tanico, *Sp.*

The present British Pharmacopœia does not give a detailed process for preparing tannic acid; the former British Pharmacopœia adopted a process which was almost identical with that of the U. S. P. 1870, both being essentially the process of Leconnet, modified by Dominé, which had been substituted for that of Pelouze previously employed in both Pharmacopœias. The process of the British Pharmacopœia (1885) was as follows: "Galls in powder, Ether, of each a sufficient quantity. Expose the powdered galls to a damp atmosphere for two or three days, and afterwards add sufficient ether to form a soft paste. Let this stand in a well-closed vessel for twenty-four hours, then, having quickly enveloped it in a linen cloth, submit it to strong pressure in a suitable press, so as to separate the liquid portion. Reduce the pressed cake to powder, mix it with sufficient ether, to which one-sixteenth of its bulk of water has been added, to form again a soft paste, and press this as before. Mix the expressed liquids, and expose the mixture to spontaneous evaporation until, by the aid subsequently of a little heat, it has acquired the consistence of a soft extract; then place it on earthen plates or dishes, and dry it in a hot-air chamber at a temperature not exceeding 212° F. (100° C.)." *Br.* (1885).

While the Pelouze process yields the tannic acid probably in a somewhat purer state than Leconnet's, it is less easy of performance, and much less productive, and the product of the above formula is sufficiently pure for all practical purposes. The addition of a little alcohol—8 per cent., for example—to the ethereal menstruum still further increases the product. The exposure of the powdered galls to a damp atmosphere for two or three days is for the purpose of inducing a special fermentation, whereby the yield of tannin is materially increased. There appear to be two coloring principles in galls, one soluble in ether and not in alcohol, the other in alcohol and not in ether. Hence, while the tannic acid, in whichever way procured, is yellowish, that obtained by ether has a greenish tint, while that obtained by the addition of alcohol is slightly brownish. In consequence of the mode in which the acid is dried, in thin layers, on tinned or glass plates, and equally exposed to the heat above and below, it froths up on the escape of the ether, and concretes in a soft, cellular, friable form, which is strikingly characteristic of the preparation made in strict accordance with the formula.

From a superficial examination of this process, it might appear that the result can be nothing more than an ethereal extract; but it is necessary that the ether employed should contain water, as it is directed to be washed; and yet the quantity of water is so small that it can hardly operate by its mere solvent power. The circumstances attendant upon the process of Pelouze afford the means of a satisfactory explanation, which was first suggested by Beral. In this, the powdered galls are submitted to

percolation by watered ether, and the liquid which passes separates into two layers, a heavier which sinks to the bottom and a lighter which floats upon the surface. It is the heavier which contains the tannic acid, and from which the acid is obtained by evaporation. The most probable explanation is that ether, water, and tannic acid unite to form a definite compound, in which the affinities are too feeble to resist the tendency of the ether to rise in vapor, and which is, therefore, decomposed by its evaporation. The proportion of the menstruum to the galls is very small, much smaller than would be employed to obtain an extract; and the whole or nearly the whole of both liquids is probably occupied in the formation of the definite compound referred to, thus leaving little or none to act merely as solvents. Hence the exclusion from the resulting acid, in great measure, of the other soluble constituents of the galls; and the slight amount of impurity really present in the acid is probably owing to the action of that small quantity of the menstruum not occupied in forming the liquid compound. Opinion is not altogether united in this explanation, but it is that which appears to us the best to account for the phenomena of the case. It has been stated that the tannic acid obtained by either process has a more or less yellowish tint. From this, according to F. Kummel, it may be freed by the percolation, through recently ignited animal charcoal, of its solution in a mixture of ether and alcohol. It has, too, a slight odor, which, according to Procter, is derived from a volatile odorous principle existing in galls, which he succeeded in separating from the acid by the action of benzene. From 30 to 35 per cent. of tannic acid is obtained from galls by Pelouze's method; 60 per cent. by that of Leconnet. Alcohol tannin and water tannin are terms used to indicate the method of extraction; in the former the powdered nutgall is percolated with alcohol (50 per cent.) and the solution of tannin evaporated in a vacuum apparatus; in the water tannin, water is used as in the ether process as above described and the aqueous solution evaporated *in vacuo*. Gartenmeister used acetic ether for a solvent and a patent was secured for this process in Germany.

Crystallized tannic acid is said to be made by forcing a thick syrupy solution of tannin through finely perforated sieves and dropping the threads from a height upon rapidly revolving wooden cylinders and scraping off the product. The term crystallized is of course a misnomer, as tannin is amorphous. For the preparation of tannin from Chinese galls, Oscar Rothe proposes the following as a superior process. Macerate eight parts of the powdered galls with twelve of ether and three of strong alcohol for two days, decant, renew the menstruum, and finally express. Mix the liquids, and after standing decant from the sediment, add twelve parts of water, recover the alcohol and ether by distillation, rapidly filter the

aqueous solution, and quickly evaporate by means of a steam bath; dry, and pulverize the residue. (*A. J. P.*, xlii. 403.)

Henry Trimble and J. C. Peacock recommend acetone as a valuable solvent for extracting tannin from oak bark (*Proc. A. Ph. A.*, 1893, p. 110), and acetone is now largely used by manufacturers as a solvent in extracting tannin from galls. B. L. DeGraffe (*A. J. P.*, 1896, 313) recorded investigations upon the plants of the *Ericaceæ* to determine the character of their tannins; acetone and acetic ether were used as solvents. For Sisley's method of preparing pure tannin, see *Proc. A. Ph. A.*, 1894, 1087.

The term *tannin* is applied to a class of vegetable principles the aqueous solutions of which give blue or green colors or precipitates with ferric salts, and precipitate solutions of gelatin and albumin. They are mainly glucosides. Chemists have recognized two kinds, one distinguished by producing a bluish-black precipitate with ferric salts, and the other characterized by producing a greenish-black or dark olive precipitate with the same salts. The former is the one which has received most attention, and from an examination of which the characters of tannin have generally been given. It is the substance described in this article. It is called, for the sake of distinction, *gallotannic acid*. According to Pettenkofer, it is found only in perennial plants, indicating some relation to the production of woody fibre. (*Buchner's Neues Repert.*, iii. 74-76.) Henry Trimble (*The Tannins*, vol. ii. p. 132, Phila., 1894) classifies the tannins into two main groups: Group a. Gallotannic acid, chestnut wood tannin, chestnut bark tannin, pomegranate bark tannin, and sumac tannin. Group b. Oak bark tannin, mangrove tannin, canaigre tannin, rhatany tannin, kino tannin, catechu tannin, and tormentil tannin. R. Wagner (*Bull. Soc. Chim.*, 1866, ii. 461) divides tannin into two great classes: pathological, found only in diseased vegetable tissue, as gallotannic acid, etc.; and physiological, occurring in leaves, bark, wood, etc. in a natural state, as quercitannic acid, etc.

For another scheme of classification of the tannins, based on the products they yield when heated alone, when heated with diluted acid, and when fused with caustic alkali, see Allen, *Com. Org. Anal.*, 2d ed., vol. iii., part i., p. 77.

Properties.—Pure tannic acid is solid, uncrystallizable, white, or slightly yellowish, odorless; taste strongly astringent without bitterness, very soluble in water, much less soluble in alcohol and ether, especially when anhydrous, insoluble in the fixed and volatile oils.

The U. S. Pharmacopœia thus describes this acid: "A light yellowish, amorphous powder, gradually turning darker when exposed to air and light, usually cohering in the form of glistening scales or spongy masses, odorless, or having a faint, characteristic odor, and a strongly astringent taste. Soluble in about 0.34

part of water and in about 0.23 part of alcohol at 25° C. (77° F.); very soluble in boiling water, and in boiling alcohol; also in about 1 part of glycerin, with the application of a moderate heat; freely soluble in diluted alcohol, sparingly in absolute alcohol; almost insoluble in absolute ether, chloroform, benzene, or petroleum benzin. When heated on platinum foil, the Acid is gradually consumed, leaving not more than 0.2 percent. of ash. An aqueous solution of Tannic Acid reddens blue litmus paper. The addition of a small quantity of ferric chloride T.S. to an aqueous solution of the Acid produces a bluish-black color or precipitate. On adding to an aqueous solution (1 in 100) of Tannic Acid a small quantity of calcium hydroxide T.S., a pale bluish-white, flocculent precipitate is produced which is not dissolved on shaking (difference from *gallic acid*), and which becomes more copious and of a deeper blue by the addition of a moderate excess of calcium hydroxide T.S., while a large excess of the latter imparts a pale pinkish tint to the solution. The aqueous solution of the Acid produces precipitates with most alkaloids and glucosides, and with test solutions of gelatin, albumin, and starch (distinction from *gallic acid*). If 2 Gm. of Tannic Acid be dissolved in 10 Cc. of boiling water, and the liquid allowed to cool, no turbidity should be produced on diluting 5 Cc. of the solution with 10 Cc. of alcohol (absence of *gum* or *dextrin*), or with 10 Cc. of water (absence of *resinous substances*). U. S. "It is precipitated from its aqueous solution and loses its astringency in the presence of many mineral salts and acids. The aqueous solution precipitates solutions of *isinglass*, *albumen*, alkaloids, and *tartarated antimony*, and gives with *test-solution of ferric chloride* a bluish-black color. It should leave no appreciable residue when incinerated with free access of air." Br.

Commercial tannic acid often has a decided odor, which Procter, after a practical investigation, believed to be owing chiefly to the presence of the odorous principle of the galls, though sometimes to matter derived from the ether with which it is prepared. (*A. J. P.*, 1865, p. 53.) According to Heinz, the odor is due to a greenish resinous principle, which may be separated by dissolving the acid in twice its weight of hot water, adding one-fourth part of ether, agitating slowly, allowing the coagulated coloring matter to precipitate, filtering, and evaporating. (*J. P. C.*, xv. 308.)

Exposed to heat, tannic acid partly melts, swells up, blackens, takes fire, and burns with a brilliant flame. Thrown on red hot iron, it is entirely dissipated. Its solution reddens litmus, and it combines with most of the salifiable bases. It forms with potassium hydroxide a compound but slightly soluble, and is, therefore, precipitated by this alkali or its carbonates from a solution which is not too dilute, though a certain excess of alkali will cause the precipitate to be redissolved. Its combination

with soda is much more soluble, and this alkali affords no precipitate, unless with a very concentrated solution of tannic acid. With ammonia its relations are similar to those with potassium hydroxide. Lime and magnesia added in the state of hydroxides, form with it compounds of little solubility. The same is the case with most of the metallic oxides, when presented in the state of salts to a solution of potassium tannate. Tannic acid even when in the uncombined state precipitates many of the metallic salts, especially those of lead, copper, silver, uranium, chromium, mercury, antimony trioxide, and stannous oxide. With ferric salts it forms a black precipitate, which is a compound of tannic acid and the iron, and is the basis of ink. It does not disturb the solutions of the pure ferrous salts. Several of the alkaline salts precipitate it from its aqueous solution, either by the formation of insoluble compounds or by simply abstracting the solvent. Potassium chlorate when rubbed up with it explodes with great violence, and several serious accidents are recorded as having occurred during the attempt to dispense such a mixture.

Tannic acid unites with most of the vegetable alkaloids, forming compounds which are for the most part of a whitish color, and but very slightly soluble in water, though they are soluble in the vegetable acids, especially acetic, and in alcohol. In this latter respect they differ from most of the compounds which tannic acid forms with other vegetable principles. On account of this property of tannic acid, it has been employed as a test for some of these alkaloids.

Tannic acid when in solution affords precipitates with sulphuric, nitric, hydrochloric, phosphoric, and arsenic acids, but not with oxalic, tartaric, lactic, acetic, or citric. The precipitates are considered as compounds of tannic acid with the respective acids, and are soluble in pure water, but insoluble in water with an excess of acid. Hence, in order to insure precipitation, it is necessary to add the acid in excess to the solution of tannic acid. Strecker, however, denies that the precipitates are compounds of the tannin with the acid, and maintains that they are tannin imbued with free acid.

When tannic acid, iodine, and water are mixed, a reaction takes place, by which the water is decomposed, its hydrogen forming with the iodine hydriodic acid, which combines with a portion of the tannic acid and remains in solution, while the oxygen of the water combines with another portion of the tannic acid, to form a compound, which, being insoluble, is precipitated. The iodized solution thus obtained is capable of dissolving more iodine, and holding it in permanent solution, however much diluted. (Socquet and Guilliermond, *J. P. C.*, xxvi. 280.) Iodine in a liquid containing tannic acid cannot be detected by starch, but if the liquid is placed in a watch-glass, ferrous sulphate

added, and the glass covered with a starched paper, ferric tannate being precipitated, the blue color soon appears. (*A. J. P.*, xlvii. 398.)

Griessmayer (*Zeit. An. Chem.*, 1873) proposes a test for tannin and free alkalies. On mixing a drop of a solution of tannin with 1 Cc. of 1/100 normal solution of iodine, the reddish color of the iodine solution instantly disappears; if one drop of solution of ammonia be now added (previously diluted with ten times its bulk of water), a brilliant red color is produced which is quite permanent. Tannic acid precipitates solutions of starch, albumin, and gluten, and forms with gelatin an insoluble compound, which is the basis of leather. J. Napier Spence (*J. Soc. Chem. Ind.*, 1891, p. 1114) has reviewed all the current tests for distinguishing between tannic acid and gallic acid. (See *Proc. A. Ph. A.*, 1892, p. 1032.)

Mulder gave for tannic acid the formula $C_{14}H_{10}O_5$; and both Julius Löwe and Hugo Schiff confirmed these figures. (*A. J. P.*, xxv. 223; xlvii. 208.) Schiff asserts that it is not a glucoside; that glucose exists in commercial tannic acid as an impurity, and is not a necessary part of it, and that it is a "first anhydride," formed from two molecules of gallic acid by the abstraction of water, thus:

It is consequently digallic acid; this is the present view. (See *Acidum Gallicum*.) (*Chem. News*, xxix. 73; also *A. J. P.*, xlvii. 234.)¹

Uses.—Tannic acid is the chief principle of vegetable astringents, and has an advantage over the astringent extracts in the comparative smallness of its dose, which renders it less apt to offend an irritable stomach. In most of the vegetable astringents it is associated with more or less bitter extractive, or other principle which modifies its operation and renders the medicine less applicable than it otherwise would be to certain cases in which there is an indication for pure astringency without any tonic power. Such is particularly the case in the active *hemorrhages*; and tannic acid, in its separate state, is here preferable to the native combinations in which it ordinarily exists. In *diarrhœa* it is probably more beneficial than ordinary astringents, as less liable to irritate the stomach and bowels. Owing to its very powerful coagulant action upon albumin, it is, however, absorbed only after conversion into gallic acid, and consequently has been super-

seded by the latter agent in all cases in which it must reach the diseased surface through the blood, or in which a general astringent action is desired. Internally various combinations with albumin are now largely employed (see *Tannalbin*, PART II). Locally applied, it is much more powerful than gallic acid, and is very largely employed in *hemorrhages* from external surfaces or from mucous membrane which can be reached from without, as in *relaxation of the uvula*, *coryza*, *chronic inflammation of the fauces*, *diphtheria*, *toothache*, *aphthæ*, *excessive salivation*, *leucorrhœa*, *chapped nipples*, *gleet*, *gonorrhœa*, *flabby and phagedæmic ulcers*, *piles*, *chilblains*, etc. (See *Collodium Stypticum*). It may also be applied in solution of varying concentration according to the necessities of the case. When a very powerful influence is desired, the solution in glycerin may be used. (See *Glyceritum Acidi Tannici*.) In *affections of the rectum* it may be used in the form of a suppository. In *diseases of the uterus* it has been recommended in the form of a cylindrical pencil about an inch long and two lines thick, made with 4 parts of the acid to 1 part of tragacanth, with a little crumb of bread to give the mixture due flexibility.

As already stated, tannic acid is probably converted into gallic acid before absorption; it is eliminated through the kidneys in the form of gallic and pyrogallic acids. In the largest amounts it produces only a mild gastro-intestinal irritation.

Dose, from three to ten grains (0.20 to 0.65 Gm.).

ACIDUM TARTARICUM. U. S., Br.

TARTARIC ACID

(âç'î-dûm târ-târ'î-cûm)

"A dibasic organic acid [$C_2H_3(OH)_2(COOH)_2$], usually prepared from argol. It should contain not less than 99.5 percent. of pure Tartaric Acid." *U. S.* "Tartaric Acid, or dextro-rotatory hydrogen tartrate, $C_4H_6O_6$, prepared from acid potassium tartrate. In constitution it may be regarded as dihydroxy succinic acid, or dihydroxysuccinic acid,

Dextrotartaric Acid; Sal Essentielle Tartari; Acide Tartrique, *Fr. Cod.*; Acide du Tartre, Acide dextro-racémique, *Fr.*; Acidum tartaricum, *P. G.*; Weinstein-saure, Weinsäure, *G.*; Acido tartarico, *It.*; Acido tartarico, *Sp.*

No formula for the preparation of tartaric acid is given in either Pharmacopœia. It is

¹ Various plans have been proposed for estimating the quantity of tannic acid, which is an object of importance to tanners, as enabling them to judge of their tanning materials; but on this point we must content ourselves, from want of space, with referring to *A. J. P.* (1859, p. 427; 1861, p. 164; 1863, p. 519; 1864, p. 314); also a paper by John Watts in the *P. J.* (1867, p. 515); and by the following: H. R. Procter, *Chem. News* (1874, p. 51); A. Muntz and Ramsbacher, *J. P. C.* (xx. 237); *J. P. C.*, 1874, pp. 445-447; *A. J. P.*, March, 1874, and Aug. 1877; *N. R.*, Aug. 1878; *N. R.*, 1882, pp. 150, 185; *P. J.*, 1885, pp. 121, 850. See also paper by S. J. Hinsdale (*West. Drug.*, 1891, p. 445), and a monograph on "*The Tannins*," by Henry Trimble (J. B. Lippincott Co., 1894). John H. Yocum, after reviewing various methods of estimating tannin, believes the "hide-powder" method most practical and useful. (*Am. Chem. Soc.*, Jan. 9, 1897.)

extracted from *tartar*, or *argol*, a peculiar substance which is deposited on the inside of wine casks during the fermentation. Tartar, when purified and reduced to powder, is the cream of tartar of commerce, and consists of acid potassium tartrate. (See *Potassii Bitartras*.) The following is the former British process:

"Take of Acid Tartrate of Potassium *forty-five ounces* [av.]; Distilled Water *a sufficiency*; Prepared Chalk *twelve ounces and a half* [av.]; Chloride of Calcium *thirteen ounces and a half* [av.]; Sulphuric Acid *thirteen fluidounces*. Boil the Acid Tartrate of Potassium with two gallons [Imp. measure] of the Water, and add gradually the Chalk, constantly stirring. When the effervescence has ceased, add the Chloride of Calcium dissolved in two pints [Imp. meas.] of the Water. When the tartrate of calcium has subsided, pour off the liquid, and wash the tartrate with Distilled Water until it is rendered tasteless. Pour the Sulphuric Acid, first diluted with three pints [Imp. meas.] of the Water, on the tartrate of calcium, mix thoroughly, boil for half an hour with repeated stirring, and filter through calico. Evaporate the filtrate at a low temperature until it acquires the sp. gr. of 1.21, allow it to cool, and then separate and reject the crystals of sulphate of calcium which have formed. Again evaporate the clear liquor till a film forms on its surface, and allow it to cool and crystallize. Lastly, purify the crystals by solution, filtration (if necessary), and recrystallization." *Br.* (1885).

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in potassium bitartrate or cream of tartar with calcium carbonate, and decomposing the resulting insoluble calcium tartrate by sulphuric acid, which precipitates in combination with the lime, and liberates the tartaric acid. The equivalent quantities are two molecules of the acid tartrate and one molecule of calcium carbonate. The process, when thus conducted, furnishes one half of the tartaric acid. The other half may be procured, as in the British process, by decomposing the neutral potassium tartrate remaining in the solution after the precipitation of the calcium tartrate, by calcium chloride in excess. By double decomposition, potassium chloride will be formed in solution, and a second portion of calcium tartrate will precipitate, which may be decomposed by sulphuric acid together with the first portion. The process, when thus conducted, will furnish twice as much tartaric acid as when the acid salt only is decomposed. The reactions are:

Scarlati (*Chem. News*, 1899, 296) has devised a method of making tartaric acid based on the decomposition of potassium and calcium

tartrates by *fluosilicic acid*; tartaric acid is liberated and corresponding fluosilicates are formed; the latter may then be decomposed by sulphuric acid and fluosilicic acid reproduced for use in a subsequent operation. By this method tartaric acid of 99 per cent. purity may be obtained. Zinno has prepared tartaric acid synthetically by passing carbon dioxide under pressure over potassium glycerate. (*Proc. A. Ph. A.*, 1902, 263.)

Formerly all the tartaric acid used in America was imported from England and France, the amount in some years being as much as 500,000 lbs. annually; but it is now made in the United States not only of better quality, but actually cheaper than the imported acid costs in bond. The importations of argol, or crude tartar, are, however, considerable. In 1902, they amounted to 29,286,980 lbs., valued at \$2,263,538; in 1903, to 29,481,046 lbs., valued at \$2,732,706; and in 1904, to 24,406,705 lbs., valued at \$2,549,108. According to the census of 1900 there were produced in the United States, in that year, 2,677,004 lbs. of tartaric acid, the value of which was fixed at \$781,600.

Preparation on the Large Scale.—To obtain tartaric acid from the crude materials (argol and wine lees), the method still largely used is the precipitation of the acid potassium tartrate as calcium tartrate and subsequent preparation of the tartaric acid from the latter. The methods of obtaining the calcium tartrate vary according to the nature of the crude material. A suitable method of producing it from argol is to mix the argol, preferably in the form of a powder, with water, and boil, after the addition of some hydrochloric acid. Milk of lime is then added to the boiling mass until this is nearly neutral, when calcium tartrate is precipitated and neutral potassium tartrate and calcium chloride left in solution. The neutral potassium tartrate is decomposed either by boiling with a sufficient amount of calcium sulphate or by adding calcium chloride solution, an excess of the precipitant being avoided in either case. The small amount of acid potassium tartrate purposely left in the liquid, when treating the latter with milk of lime, is decomposed with pure precipitated calcium carbonate. The object of not adding the milk of lime to the neutral point or in excess is to avoid the precipitation of iron or aluminum oxides. The solution must still remain perceptibly acid after the addition of the calcium carbonate. When cooled to about 40° C., the liquid is filtered with the aid of a suction pump, and the residue washed with water.

In the oldest methods of obtaining calcium tartrate from wine lees the latter were boiled with water and hydrochloric acid, the clear solution removed, and the residue treated with more water. As the extraction was very incomplete, these methods have not been employed of late years. When filtration of the lees was first attempted it was found that the pores of

the filter became clogged, and that even under a pressure of four or five atmospheres no liquid would pass through. This difficulty was overcome by the process of Dietrich and Schnitzer, in which the albuminoid substances are coagulated by heating for about six hours under a pressure of four or five atmospheres. Wet lees, when thus treated, can be readily filtered. Dried lees are crushed, stirred in a tank with water, and heated by steam for some time, until air is completely expelled, before being heated in the pressure boiler.

During the process of heating the lees, the steam passing from the apparatus carries with it volatile empyreumatic products derived from the decomposed albuminoids. These have a very offensive odor, and should be conveyed into a factory chimney of sufficient height, so that the evil-smelling vapors are drawn up and decomposed by the furnace gases.

When the heating is finished, the steam outlet pipe is opened and the pressure allowed to fall to from one to one-half atmosphere, this pressure being required to force the lees from the boiler into a tank, which may be suitably constructed of wood. Here they are mixed with water, which has previously been put into the tank, and the requisite quantity of crude hydrochloric acid (21° to 22° B.). Experience has shown that for every 100 parts by weight of argol in the lees 100 parts of acid are required. Too little acid causes deposition of argol in the cloths of the filter-press, while too much destroys the cloths, and more lime is needed to neutralize the filtrate. If the conditions are right, the filtered liquid should have a specific gravity of about 6° B.

The acidified lees are pressed and washed, the washings being used instead of clear water for mixing with the next charge of lees from the pressure boiler. The tartaric acid in the filtrate is precipitated with lime and calcium carbonate, and the remainder of the process is the same as in the case of the argol, with the exception that there is no necessity to add calcium chloride or calcium sulphate.

Calcium tartrate obtained from wine lees is of a clear gray color, considerably purer than the dark gray or dark brown product from argol.

Oscar Fieinus of Bensheim, proposes the following process to procure a pure tartaric acid. Saturate the crude tartar with calcium carbonate, and decompose the resulting calcium tartrate with solution of zinc chloride, whereby calcium chloride and zinc tartrate are produced. The latter is almost insoluble, and is completely decomposed by hydrogen sulphide. The residuary zinc sulphide may again be converted by means of hydrochloric acid into zinc chloride and hydrogen sulphide, so that the expense of the process is very small. The liquid filtered from the precipitated zinc sulphide, containing tartaric and sulphydric acids in solution, is heated for some time to 60° to 80° C. (140° to 176° F.), in order to dissipate the latter acid, filtered from the precipitated sulphur, and concentrated

to the point of crystallization. (*A. Pharm.*, April, 1879, p. 310.) It is asserted that in Hungary and Southern Italy tartaric acid of extreme purity is prepared, that occurring in flat, crystalline crusts being chemically pure, that in pointed crystals containing a little sulphuric acid.

Properties.—"Colorless, translucent, monoclinic prisms, or crystalline crusts, or a white powder, odorless, having a purely acid taste, and permanent in the air. Soluble in 0.71 part of water, and in 1.67 parts of alcohol at 25° C. (77° F.); in about 0.5 part of boiling water, and in about 0.2 part of boiling alcohol; also in 250 parts of ether; nearly insoluble in chloroform, benzene, or petroleum benzin. When heated for some time at 100° C. (212° F.), the powdered crystals do not suffer a sensible loss of weight. At 135° C. (275° F.) the Acid melts. At a higher temperature it is gradually decomposed, emitting an odor resembling burning sugar, and is finally consumed, leaving not more than 0.05 percent. of ash." *U. S.* "Readily soluble in less than its own weight of water and in less than three times its weight of alcohol (90 per cent.). An aqueous solution rotates the plane of a ray of polarized light to the right." *Br.* The powder is sometimes directed to be kept in well-stoppered vials; but Otto has shown that this method tends to spoil it. A better plan is to keep the powder in ordinary boxes.

As found in commerce, it is in the form of a fine white powder, prepared by pulverizing the crystals. A weak solution undergoes spontaneous decomposition when kept, becoming covered with a mouldy pellicle; but, if boiled and filtered, it is said to lose this tendency. It is asserted that the addition of 1-1000th of salicylic acid will effectually preserve solutions of tartaric acid. In uniting with bases it has a remarkable tendency to form double salts, several of which constitute important medicines. It combines with several of the vegetable alkaloids, so as to form salts. It is distinguished from all other acids by forming a crystalline precipitate, consisting of potassium bitartrate, when added to a neutral salt of that alkali. When associated with an excess of boric acid, it is detected with difficulty, potassium hydroxide not precipitating it, even with the addition of acetic or hydrochloric acid. Its separation, however, may be effected, according to Barfoed, by means of potassium fluoride, which detaches the boric acid, to form potassium fluoborate, and renders free the tartaric acid, which then responds to the ordinary test. (*J. P. C.*, 4e sér., ii. 70.) Its most usual impurity is sulphuric acid, which may be detected by the solution affording with lead acetate a precipitate only partially soluble in nitric acid. When incinerated with mercuric oxide, it leaves no residue, or a mere trace. The British Pharmacopœia directs that "each gramme of tartaric acid dissolved in water should require for neutralization 13.3 cubic centimetres of the

volumetric solution of sodium hydroxide. It should yield no characteristic reaction with the tests for copper, arsenium, iron, potassium, sodium, or oxalates, only the slightest reactions with the tests for calcium or sulphates, and no reaction for lead by the test described under 'Acidum Citricum.' On incineration with free access of air, it should not yield more than 0.05 per cent. of ash." *Br.* "An aqueous solution of Tartaric Acid reddens blue litmus paper. An aqueous solution (1 in 2) of the Acid mixed with a strong solution (1 in 3) of potassium acetate yields a white crystalline precipitate, which is soluble in solutions of alkalies and in mineral acids, but insoluble in acetic acid. The aqueous solution (1 in 10) of the Acid, acidulated with a few drops of hydrochloric acid, should remain unaffected by barium chloride T.S. (absence of *sulphuric acid*). An aqueous solution (1 in 10) in which the free Acid has been nearly but not entirely neutralized by ammonia water, should not be affected by calcium sulphate T.S. (absence of, and difference from, *oxalic acid*). On supersaturating 10 Cc. of the aqueous solution (1 in 10) with ammonia water, no more than a faint turbidity should be produced in the liquid by ammonium oxalate T.S. (absence of more than a trace of *calcium*), nor should the aqueous solution (1 in 10) mixed with a few drops of hydrochloric acid show any color in the acid solution when submitted to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121), omitting the subsequent addition of ammonia water. To neutralize 3.73 Gm. (3.723) of Tartaric Acid should require not less than 49.3 Cc. of normal potassium hydroxide V.S. (each Cc. corresponding to 2 percent. of pure Tartaric Acid), phenolphthalein T.S. being used as indicator." *U. S.* Denigès gives the following modification of Mohler's test for tartaric acid. A solution of 2 Gm. of resorcinol in sufficient diluted sulphuric acid (1 per cent.) is added to 20 times its volume of strong sulphuric acid. In the presence of tartaric acid this liquid gives with a few drops of the fluid to be tested a characteristic violet-red color when the mixture is heated to 115° to 140° C. (*Am. Drug.*, 1896, 182.)

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassium, with which it produces a crystalline precipitate of bitartrate; and with the salts of calcium and lead, with which it also forms precipitates. It consists of four atoms of carbon, six of hydrogen, and six of oxygen. Of the six hydrogen atoms, however, only two are replaceable by metal, so that it is dibasic, and can form both acid and neutral salts with monad elements like potassium and sodium. Thus, cream of tartar is the acid potassium tartrate (potassium bitartrate), and the so-called "soluble tartar" is the neutral potassium tartrate.

MODIFICATIONS OF TARTARIC ACID.—Five distinct modifications of tartaric acid exist. Their chief physical and chemical differences are:—

a. Dextro-tartaric acid, or ordinary tartaric acid, forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the right. The crystals fuse at 135° C. (275° F.), have a sp. gr. of 1.74 to 1.75, and are readily soluble in absolute and aqueous alcohol.

b. Lævo-tartaric acid forms anhydrous, hemihedral, rhombic crystals, the aqueous solution of which turns the plane of polarization of a luminous ray to the left.

c. Racemic or para-tartaric acid forms hydrated, holohedral, triclincic crystals of $\text{H}_2\text{C}_4\text{H}_4\text{O}_6 + \text{H}_2\text{O}$, which are optically inactive. The crystals have a sp. gr. of 1.69, and are soluble in five parts of cold water and with difficulty in cold alcohol. The calcium racemate is less soluble in water than calcium dextro-tartrate, and is also distinguished by its insolubility in acetic acid and in ammonium chloride solution. Racemic acid can be prepared by mixing *a*- and *b*-tartaric acids, and can be resolved into them by appropriate methods. Racemic acid exists naturally in small proportion in the juice of grapes growing in particular localities, and was first obtained artificially in 1853 by Pasteur.

d. Inactive or meso-tartaric acid, optically inactive, but not resolvable into *a* and *b* acids.

e. Meta-tartaric acid, produced by fusing the ordinary variety. It is deliquescent and uncrystallizable. Its solution and the solutions of its salts are converted by boiling into those of the ordinary modification.

Uses.—Tartaric acid, being cheaper than citric acid, forms, when dissolved in water and sweetened, an available substitute for lemonade. It may be improved by adding a drop of fresh volatile oil or a few drops of spirit of lemon. Dried by a gentle heat, and then mixed with sodium bicarbonate, in the proportion of thirty-five grains of the acid to forty of the bicarbonate, it forms a good effervescing powder, the dose of which is a teaspoonful (3.9 Gm.) stirred in a tumbler of water. Tartaric acid resembles citric acid in its medicinal properties, but is more irritant, and taken in large amount and concentrated form has caused fatal gastro-intestinal inflammation. It is chiefly used in medicine in the preparation of effervescing draughts and the official effervescing salts. For the preparation of *solution of magnesium tartrate* see *U. S. D.*, 18th edition, p. 106.

Dose, from five to thirty grains (0.32 to 2.0 Gm.).

ACIDUM TRICHLORACETICUM. U. S.

TRICHLORACETIC ACID

(ăc'î-dŭm trî-čhlŏr-ă-cēt'î-cŭm)

"A monobasic organic acid $[\text{CCl}_3\text{COOH}]$, usually obtained by the oxidation of hydrated chloral with nitric acid. It should be kept in dark amber-colored, well-stoppered bottles in a cool place." U. S.

Acide trichloracétique, *Fr.*; Acidum trichloraceticum, *P. G.*; Trichloressigsäure, *G.*

Three forms of chloracetic acid are known, mono-, di-, and tri-chloracetic acids, having the following formulas respectively, $\text{C}_2\text{H}_3\text{ClO}_2$, $\text{C}_2\text{H}_2\text{Cl}_2\text{O}_2$, and $\text{C}_2\text{HCl}_3\text{O}_2$. *Monochloracetic acid* may be prepared by acting upon glacial acetic acid containing 10 per cent. of iodine with dry chlorine, reserving the portion distilling over between 180°C . and 188°C . *Dichloracetic acid* distills over between 189° and 191°C . *Trichloracetic acid*, discovered by Dumas in 1838, may be most conveniently prepared by treating hydrated chloral with three times its volume of fuming nitric acid, and placing the whole mixture in the sunlight until the red fumes have disappeared; the liquid is then distilled, and the portion coming over at 195°C . is pure trichloracetic acid. All the chloracetic acids are powerful caustics, destroying the epidermis. They form various salts, most of which are easily soluble in water. The mono- and tri-acids are solid, crystalline, deliquescent bodies; dichloracetic acid is a colorless liquid having a suffocating odor, and crystallizing at 0°C .

While trichloracetic acid is usually formed by the oxidation of hydrated chloral with nitric acid, it may also be obtained by the action of potassium permanganate in concentrated solution upon hydrated chloral, the potassium trichloracetate crystallizing out in white silky crystals. The reduction of trichloracetic acid to acetic acid can be accomplished by the use of nascent hydrogen.

It is officially described as in "white, deliquescent, rhombohedral crystals, having a slight characteristic odor. Very soluble in water, alcohol, and ether. The aqueous solution, on boiling, is decomposed with the formation of chloroform and carbon dioxide. Heated to 52°C . (125.6°F .) it melts, and at 195°C . (383°F .) it boils and vaporizes without leaving a residue. An aqueous solution of Trichloracetic Acid has an acid reaction upon blue litmus paper. On heating with potassium hydroxide T.S., it is decomposed with the formation of chloroform and potassium carbonate. If to its aqueous solution (1 in 10) ferric chloride T.S. be added, a faint reddish color is developed. One Gm. when diluted with 50 Cc. of water should not require less than 6.1 Cc. of normal sodium hydroxide V.S. for neutralization, phenolphthalein T.S. being used as indicator." U. S.

Uses.—Trichloracetic acid is an active caustic which has been largely employed for the destruction of *papillomata*, *vascular naevi*, *chancreoids*, various small growths in the mouth, and similar minor structures. It is also actively antiseptic and is used in diluted solution, 1 in 1000 to 1 in 2000, in *ozæna* and other forms of chronic inflammation of the nose, pharynx and tonsils. It has also been used for *gleet* in solutions of from 1 to 5 per cent. As its action is purely local it is not employed in internal medicine.

ACONITINA. U. S., Br.

ACONITINE

(ă-cŏn-î-tî'nă)

"An alkaloid obtained from Aconite. It should be kept in amber-colored, well-stoppered vials." U. S. "An alkaloid obtained from Aconite Root, and having the formula $\text{C}_{33}\text{H}_{45}\text{N O}_{12}$." Br.

Aconitia, Aconitinum, Aconitin; Aconitine, *Fr. Cod.*; Aconitin, *G.*; Aconitina, *It., Sp.*

Formerly a process for the manufacture of aconitine was given in the U. S. and Br. Pharmacopœias, but in the 1880 revision the so-called alkaloid was dropped from the U. S. P., while in the late revision of the Br. Ph. the process of manufacture was omitted. Aconitine was again made official in the U. S. Pharmacopœia 8th Revision.

Crystallized aconitine was first made known by the researches of Groves (*P. J.*, 2d ser., viii. 121), but it was elaborately studied by Duquesnel. The methods of obtaining it differ, but, according to Patrouillard (*J. P. C.*, 4e sér., xix. 151), that of Duquesnel gives much the larger yield. It is as follows: 100 parts of the powdered roots having been mixed with one part of tartaric acid, and the whole exhausted by repeated percolation with cold alcohol, the liquid is evaporated at a low temperature on a water bath to the consistence of a fluidextract. To this, distilled water is added, and the precipitated resinous and oily matters removed by filtration. The solution of aconitine tartrate is then precipitated with a slight excess of potassium bicarbonate, agitated with washed ether, and the two fluids separated with a siphon. The ethereal solution is shaken four or five times with a 10 per cent. solution of hydrochloric acid, which takes up the alkaloids from the ethereal solution. The acid liquids are treated with calcium carbonate to saturation in order to prevent the prolonged and injurious action of the acid upon the crystallizable aconitine, the mixture is evaporated at a very gentle heat, filtered, and while still warm mixed with a solution of sodium nitrate (2 of salt to 3 of water) having the same temperature. The whole is allowed to cool slowly during several

hours, and set away for several days' rest, when the crystals separate out as a crust on the bottom.

Pure aconitine may exist in an amorphous or in a crystalline form. The official product is always crystalline, but of amorphous aconitine there are two varieties, the hydrated and the anhydrous. When the alkaloid is dried at ordinary temperature, it retains 20 (Hager) or 25 (Hottot) per cent. of water; but when dried at the temperature of the water bath, it is anhydrous, and is then *not* soluble in 50 parts of boiling water. (Hager, *A. J. P.*, xlvii. 210.) For Hottot's process of preparing aconitine, see 15th ed. U. S. D.

The amorphous aconitine of commerce is of very uncertain composition and value, and should never be substituted for official aconitine.

Properties.—The U. S. P. (8th Rev.) describes aconitine as occurring in "colorless or white rhombic tables or prisms, possessing no odor, permanent in the air, and producing, in extremely diluted solutions, a characteristic tingling sensation when brought in contact with the mucous surfaces of the tongue or lips. *The alkaloid itself should never be tasted, and its solutions only when largely diluted, and then with the utmost caution.* Soluble in 3200 parts of water, 22 parts of alcohol, 44 parts of ether, 5.6 parts of benzene, and 3580 parts of petroleum benzin, at 25° C. (77° F.); also very soluble in chloroform. When heated rapidly, Aconitine melts at 195° C. (383° F.); when heated slowly, decomposition takes place, and it melts at 182° C. (359.6° F.). Upon ignition, it is consumed without leaving a residue. Aconitine solutions have an alkaline reaction upon litmus, and are lœvogyrate. Aconitine, when dropped upon sulphuric or nitric acids, should produce no color, but if rubbed with sulphuric acid containing a crystal of ammonium vanadate, an orange color is produced. Dilute solutions of Aconitine yield precipitates with mercuric potassium iodide T.S., tannic acid T.S., and gold chloride T.S., but only concentrated solutions yield precipitates with platinic chloride T.S., mercuric chloride T.S., and picric acid T.S. On evaporating 0.01 Gm. of Aconitine with 5 drops of fuming nitric acid, the resulting yellow residue, when cooled, should not yield a violet color when treated with alcoholic potassium hydroxide T.S. (difference from *pseudaconitine* and *atropine*). Any soluble salt of Aconitine in dilutions of 1 in 1000 produces, with a drop of potassium permanganate T.S., a blood-red precipitate of aconitine permanganate. Aconitine containing decomposition products (amorphous Aconitine) forms this precipitate only in solutions containing not less than 1 in 200. (Cocaine, hydrastine, and papaverine also yield similar precipitates, but only when in more concentrated solutions.)"

U. S.
Aconitine as defined by the Br. Pharmacopœia is in "colorless hexagonal prisms of the rhombic system. Melting point 372.2° to 374°

F. (189° to 190° C.). Slightly above this temperature it yields acetic acid. Readily soluble in *alcohol* (90 per cent.) or *chloroform*, less readily in *ether*. Nearly insoluble in *water* and in *petroleum spirit*. An alcoholic solution of the alkaloid turns the plane of a ray of polarized light to the right. A drop of even an extremely dilute solution (not more than one-tenth per cent.) when placed on the tongue produces a persistent tingling sensation. The salts of Aconitine are crystalline. The hydrochloride melts at 300.2° F. (149° C.) and the hydrobromide at 327.2° F. (164° C.). A dilute solution of the alkaloid, even 1 part in 4000 parts of *water*, faintly acidulated with *acetic acid*, deposits a red crystalline precipitate on the addition of a few drops of *solution of potassium permanganate*." Br. It restores the blue color of litmus reddened by acids, and neutralizes the acids, forming crystallizable salts. The solution of these salts produces a white precipitate with platinic chloride, a yellowish with auric chloride, and a yellowish brown with free iodine. Aconitine is precipitated from the solution by caustic alkalies, but not by ammonium carbonate or potassium and sodium bicarbonates. A spurious substance has sometimes been sold under the same name, which is nearly or quite inert; and at best the alkaloid is apt to be of uncertain strength as found in commerce.

For E. R. Squibb's physiological tests for aconitine and aconite preparations, see page 91. Its only peculiar color reaction is obtained with difficulty by dissolving in diluted phosphoric acid and evaporating, when at a certain degree of concentration a violet coloration appears.

The investigations of C. R. A. Wright upon *Aconitum Napellus*, which were fully stated in a previous edition (16th ed., p. 125), have been corrected in part by later studies by Wyndham Dunstan (*J. Chem. S.*, May, 1891, April and May, 1892.) He has shown that the roots of true *Aconitum Napellus* contain four alkaloids, of which one is crystallized and three are amorphous: *aconitine*, to which he gives the formula $C_{33}H_{45}NO_{12}$ instead of the formula $C_{33}H_{43}NO_{12}$ proposed by Wright; *aconine*, $C_{35}H_{41}NO_{11}$ instead of the formula $C_{35}H_{39}NO_{11}$ proposed by Wright; *napelline*, or *isoaconitine*, which was shown by Dunstan (*P. J.*, 1893, 625) to have the composition $C_{35}H_{45}NO_{12}$, and is thus isomeric with aconitine. *Aconitine* melts at 188.6° C. (371.5° F.), "189°-190° C. (372.2°-374° F.)." Br.; and *aconine* when purified melts at 132° C. (269.6° F.). Dunstan was able by heating aconine together with ethyl benzoate in a sealed tube to effect the synthesis of the anhydride of aconitine. The *picraconitine* of Wright is considered by Dunstan to have been a mixture. In a later communication (*P. J.*, 1893, p. 1045) Dunstan shows that the roots of *Aconitum Napellus* contain, besides the highly poisonous aconitine, an almost non-poisonous isomeride, *isoaconitine*. Both furnish the same

hydrolytic products,—viz., aconine and benzoic acid. Aconitine hydrobromide (melting point 163° C.), when heated in aqueous solution, is very gradually changed into the isomeric isoaconitine hydrobromide (melting point 282° C.). The change is facilitated by the presence of a small quantity (1 to 2 per cent.) of free hydrobromic acid, but is not assisted if sufficient is present to induce hydrolysis of a large proportion of the aconitine. The hydrolysis of napelline, or aconitine, into aconine and benzoic acid is represented by the following equation:

Aconitum ferox was examined by Wright. In it he found chiefly the alkaloid *pseudaconitine*, $\text{C}_{36}\text{H}_{49}\text{NO}_{12}$.¹ It crystallizes in transparent needles and sandy crystals, but is apt to separate as a varnish if not evaporated extremely slowly. It forms crystallized salts with difficulty. It can be dehydrated, forming *apo-pseudaconitine*, $\text{C}_{36}\text{H}_{47}\text{NO}_{11}$, and when saponified yields dimethyl-protocatechuic acid instead of benzoic, and a new base, *pseudaconine*,

Pseudaconitine crystallizes with H_2O and melts at 104° to 105° C. (219.2° to 221° F.). Dunstan and Carr (*J. Chem. S.*, 1897, 350) give a process for making the very poisonous alkaloid *pseudaconitine*, which they obtained in crystals; it dissolves in hot water, very slightly in cold water, readily in alcohol, chloroform, and acetone, less readily in ether. The products of hydrolysis, which occurs in two stages, result in the separation of *veratryl pseudaconine*, $\text{C}_{34}\text{H}_{47}\text{NO}_{11}$, and *pseudaconine*, $\text{C}_{25}\text{H}_{35}\text{O}_8$; *veratric acid* is eliminated. *Pyropseudaconitine*, $\text{C}_{34}\text{H}_{45}\text{NO}_{10}$, an anhydride of *veratryl pseudaconine*, did not appear to be poisonous. In Japanese aconite roots (species not certainly known) Wright found a larger percentage of active alkaloids than in either of the other varieties. He also considers that he has obtained here a new base, *japaconitine*, $\text{C}_{36}\text{H}_{48}\text{N}_2\text{O}_{21}$. This base on saponification splits up into benzoic acid and a base, *japaconine*, $\text{C}_{26}\text{H}_{41}\text{NO}_{10}$.²

¹ *Pseudaconitine* has been physiologically studied by Boehm and Ewens (*A. E. P. P.*, 1873, 1) and by Cash and Dunstan (*P. Tr. R. S. L.*, Series B., 1902), who are in accord in finding that its physiological action is that of aconitine save only in regard to strength. 0.4 gr. of it is said to be equivalent in toxic power to 0.45 of true aconitine. *Japaconitine*, the alkaloid of Japanese aconite, *Kusa-Usa*, *A. japonicum* or *A. Fischeri*, according to Cash and Dunstan, acts physiologically as true aconitine, except that 0.85 gr. is equivalent to 0.9 in toxicity. For local application these three alkaloids may be substituted for aconitine.

² *Aconitine Derivatives*.—Certain alkaloids have been prepared by Cash and Dunstan by the withdrawal of the acetyl group from aconitine (*Philosophical Trans.*, 1898, vol. 190; and 1902, vol. 195); of these *benzaconine*, in which an acetyl group of aconitine is replaced by an atom of hydrogen, has been found to differ physiologically entirely from aconitine; being, in fact, so far as its action on the heart is concerned, antagonistic to the parent alkaloid. *Pyraconitine* differs from aconitine by the loss of one molecule of acetic acid. It differs physiologically from aconitine chiefly in being devoid of

Aconitine exists in the root in combination with *aconitic acid*, $\text{C}_6\text{H}_5\text{O}_6$. Dragendorff and Spohn (*J. P. C.* (5), 10, 361-368) find in *Aconitum Lycoctonum* two alkaloids; *lycaconitine*, $\text{C}_{27}\text{H}_{35}\text{N}_2\text{O}_8 + 2\text{H}_2\text{O}$, which is not crystalline, nor does it yield a crystalline aurochloride or platinumchloride, and *myoconitine*, $\text{C}_{27}\text{H}_{35}\text{N}_2\text{O}_8 + 5\text{H}_2\text{O}$, which is amorphous. The former alkaloid, heated with water under pressure, gives rise to two acids, a volatile one and a crystalline one, *lycoconic acid*, $\text{C}_{17}\text{H}_{15}\text{N}_2\text{O}_7$, while two alkaloids remain dissolved, one, *lycaconine*, soluble in ether, the other soluble in chloroform, and apparently Hübschmann's *acolytine*.

Hübschmann is said to have extracted two alkaloids from *A. Lycoctonum*; one in the form of a white powder, insoluble in ether, but soluble in water and alcohol, which he names *acolytine*; the other crystallizable, very soluble in alcohol, and but slightly so in ether or water, and named by him *lycoconine*. (*A. J. P.*, 1866, p. 376.) According to Flückiger, *lycoconine* is in white acicular crystals, melting like aconitine in boiling water, though at a somewhat higher heat. On cooling it crystallizes only when moistened with water, when the amorphous mass is converted into tufted crystals. It loses no water upon melting, and combines with none on crystallizing. It readily dissolves in chloroform, and upon evaporation is left as an amorphous varnish, which on the addition of a little water becomes strikingly crystalline. It is largely dissolved by carbon disulphide, ether, alcohol, the fixed and volatile oils, amyl alcohol, and petroleum benzin; but requires 600 parts of boiling water for solution. The solution is bitter and has an alkaline reaction, and with bromine water produces fine yellow crystals; and this effect results though the solution contain only one part of the alkaloid in 30,000. *Lycoconine* is an alkaloid quite distinct from aconitine and *pseudaconitine*, and is much less poisonous than either. (Flückiger, *P. J.*, 1870, p. 122.) Wright and Luff concluded that *lycoconine* and *acolytine* are identical with *aconine* and *pseudaconine*, decomposition products respectively of aconitine and *pseudaconitine*, but according to Dragendorff and Spohn they are really decomposition products of two previously unnoticed alkaloids of *A. Lycoctonum*, namely, *lycaconitine* and *myoconitine*. (See p. 87; also *P. J.*, viii. 169, and xv. 104.) Jacobowsky found *lycaconitine* to resemble curare in its physiological action, but to be of no value in practical medicine.

local action; it slows the heart by stimulating the vagus, at the same time depressing the heart muscles or its ganglia, and is a powerful respiratory and centric motor depressant. *Methylbenzaconine* differs from aconitine in that an acetyl group has been replaced by a methyl group. It is much less active locally and less poisonous than aconitine; it is a somewhat feeble cardiac depressant, but this is especially characterized physiologically by a curare-like action upon the motor nerves. It seems, also, to have influence upon the muscles, producing in the frog marked persistent fibrillary contractions even at a time when the reflexes are abolished.

Even different specimens of apparently pure crystallized aconitine made by the same chemist in the same manner vary greatly in toxic property. (See K. F. Mandelin, *A. Pharm.*, 1885, xxiii.; abstracted, *P. J.* xvi.; Bunzen and Madsen, *Trans. Internat. Congress*, Copenhagen, 1884.) Lepine states that the crystallized alkaloid made from plants gathered in Switzerland is much more active than that from plants of the Vosges or of the Pyrenees. (*S. M.*, March 30, 1892.)

Uses.—The various products obtained from aconite sold in the market as aconitine vary so enormously in their purity, nature, and toxic properties, that the alkaloid should scarcely be used internally. According to Cash and Dunstan (*B. M. J.*, 1901, ii.) there are four commercial brands of aconitine. *Amorphous aconitine*, a mixture of various alkaloids, but principally consisting of aconitine and picroaconitine, and being from fifteen to twenty times less poisonous than pure crystallized aconitine; *crystallized aconitine*, the official alkaloid; *pseudoaconitine*, obtained from *Aconitum ferox*, which is nearly twice as toxic as crystallized aconitine; *japaconitine*, from *Aconitum japonicum*, which is twenty per cent. more powerful than crystallized aconitine. Two and a half grains of commercial aconitine have been taken almost with impunity, and 1-50th of a grain has nearly proved fatal; indeed, a fatal case of poisoning by half a milligramme (1-128th gr.) of pure aconitine is reported (*J. P. A.*, Feb. 1890). One-tenth of a milligramme (1-640th gr.) should be considered the maximum dose of the alkaloid. Tison (*Atti Dell' xi. Cong. Med. Intern.*, iii., 1894) considers this the ordinary dose of the crystallized aconitine nitrate, and repeats it at such intervals that one milligramme is taken in twenty-four hours.

Even as an external remedy, aconitine is of very limited value. It produces in the skin a sensation of heat and prickling, followed by numbness, lasting, according to the quantity applied, from two to twelve hours or more. Applied much diluted and in a minute quantity to the eye, or even to the upper eyelid, it causes contraction of the pupil, with an almost intolerable sense of heat and tingling. Turnbull employed it with benefit in *neuralgia*, *gout*, and *rheumatism*. If the alkaloid be pure, the ointment should not exceed ten grains to the ounce, and even then must be used with great caution by friction over the part affected, to be continued till the peculiar sensation above described is produced, and to be repeated three or four times, or more frequently, during the day. No good can be expected unless the sensation alluded to be experienced in a greater or less degree. Care should be taken not to apply the medicine to an abraded surface, or to a mucous membrane, for fear of poisoning.

Dose, one eight-hundredth to one four-hundredth of a grain (0.00008 to 0.00015 Gm.).

ACONITUM. U. S. (Br.)

ACONITE

(ăc-q-nî'tūm)

"The dried tuberous root of *Aconitum Napellus* Linné (Fam. *Ranunculaceæ*), collected in autumn; yielding, when assayed by the process given below, not less than 0.5 percent. of aconitine." *U. S.* "The root of *Aconitum Napellus*, Linn., collected in the autumn from plants cultivated in Britain, and dried." *Br.*

Aconiti Radix, *Br.*; Aconite Root, Monkshood, Wolfsbane, Wolfroot, Friar's cap, Cuckoo's cap, Blue rocket; Racine d'Aconite, Aconit, Coqueluchon, Aconit Napel, *Fr.*; Tubera Aconiti, *P. G.*; Eisenhut, Eisenbutknollen, Sturmhut, Mönchskappe, Aconitknollen, *G.*; Aconito, *It.*, *Sp.*

The *U. S. Pharmacopœia* formerly recognized aconite leaves under the name of *Aconiti Folia*.

The plants belonging to this genus are herbaceous, with divided leaves, and violet, yellow, or white flowers, in spikes, racemes, or panicles. In the *Paris Codex* three species were recognized as official, *A. Anthora*, *A. cammarum*, and *A. Napellus*; but the French authorities unite at present with our own and the British in acknowledging only *A. Napellus*. There has been much difference of opinion as to the plant originally employed by Störck. Formerly thought to be *A. Napellus*, it was afterwards generally believed to be *A. neomontanum* of Willdenow, and by De Candolle was determined to be a variety of his *A. paniculatum*, designated as *Störckianum*. It is probable that this species, which is not infrequent in the Alps, yields much of the aconite of commerce, as probably does also *A. Lycotomum*. But, according to Geiger, *A. neomontanum* is possessed of little acrimony; and Christison states that *A. paniculatum*, raised at Edinburgh from seeds sent by De Candolle himself, was quite destitute of that property. Neither of these, therefore, could have been Störck's plant, which is represented as extraordinarily acid. *A. septentrionale*,¹ Koelle, which is

¹ Rosendahl found in *A. septentrionale* three alkaloids, to which he gave the names of lappaconitine, septentrionaline, and cynocotinine.

Lappaconitine, $C_{34}H_{48}N_2O_8$, occurs in crystals belonging to the hexagonal system, bitter in taste, melting point, 205° C.; soluble in 126 parts of alcohol, 350 of ether, 1472 of water. Its alcoholic or ethereal solution shows a reddish-violet fluorescence. It is colored yellowish red by sulphovanadic acid, afterwards becoming green. It is a convulsant, which finally paralyzes the respiratory muscles; at the same time it lowers blood pressure by a direct action upon the heart, and also by an influence on the vasomotors. During the convulsion the pupils are contracted; during the paralysis they are dilated. Upon muscles, blood, lower organisms, and general protoplasm the alkaloid has no influence. It is rapidly eliminated by the urine.

Septentrionaline, $C_{34}H_{48}N_2O_8$, occurs in a white or yellowish powder of a bitter taste, with a pronounced local anæsthetic influence; melting point, 128.9° C. It is very soluble in alcohol and ether, and in 58 parts of water; its solutions are without fluorescence. It is colored cherry-red by fresh furfural sulphuric acid. When given by the mouth, septentrionaline, according to Rosendahl, produces no poisonous effects; its subcutaneous or intravenous injection is followed

generally considered by botanists to be a variety of *A. Lycoctonum*, although it differs somewhat in the shape of its leaves and is a native of Finland, Sweden, and other northern portions of Europe, has been elaborately studied by H. V. Rosendahl (*Arbeiten des Pharmakol. Institutes zu Dorpat*, 1895), who believes it to be a distinct species. There are five American species of the genus, each of which is probably active, although none of them are commercial sources of the drug. Under the name of *Bish*, or *Bikh*, or *Nepaul aconite*, an active aconite is largely sold in the bazaars of India. It has been usually attributed to *A. ferox*, Wall., a Himalayan plant with large dull blue flowers, which reaches the height of three to six feet; but according to the latest researches the roots are much longer and of smaller diameter than are those of the *A. ferox*, Wall., so that the botanical source of Nepaul aconite remains at present uncertain. In an elaborate study of the aconites of India (*P. J.*, 1903, 68) George Watt says that the botany of the poisonous Indian aconites is at present very uncertain. Of the number of varieties of *A. ferox* which have been made by authors, one or more are thought by Watt to be distinct species, and the examination of the plants in the Kew Herbarium by Stapf led him to the opinion that *A. Napellus* does not exist in India at all, *A. multifida* and *A. rotundifolia*, which have been believed to be varieties of *A. Napellus*, being really distinct non-poisonous species. A monograph on the Indian aconites has been promised by Stapf but so far as we know has not yet appeared. The non-poisonous aconites of India are affirmed to include *A. heterophyllum*, Wall., and *A. palmatum*, Don, and the species, *A. multifida*, and *A. rotundifolia*, hitherto referred to *A. Napellus*. They are said to be eaten by shepherds on the Alpine ranges, and do not appear to be collected for commercial

purposes. For a structural study of the Indian aconite roots see *P. J.*, lxvii. p. 576. Under the name of *Utees*, *Atees*, or *Atis*, the root of *A. heterophyllum*, Wall., of India, is said to be largely employed in doses of 20 grains as an antiperiodic. It yielded to Wasowicz six one-hundredths of 1 per cent. of *atisine*, an amorphous, very slightly poisonous alkaloid (the same alkaloid was pointed out by Broughton), besides aconitic acid. See *P. J.*, xvi. *Wakhma* is the root of *A. palmatum*, Don, in which Jowett found aconitic acid and the alkaloid *atisine*, $C_{22}H_{33}NO_3$, which according to Cash is physiologically very feeble. (*J. Chem. S.*, 1896.)

Aconitum Napellus, Linn., *Flor. Suec.*, ed. 1755, p. 168. *A. neubergense*, De Candolle, *Prodom.*, i. 62. *A. variabile neubergense*, Hayne, *Darstel. und Beschreib.*, xii. 14.—This is a perennial herbaceous plant, with a conical-shaped, tapering root, seldom exceeding the thickness of the finger at top, three or four inches or more in length, brownish externally, whitish and fleshy within, and sending forth numerous long, thick, fleshy fibres. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown and supports the stem, while the younger is of a light yellowish brown, and is destined to furnish the stem of the following year, the old root decaying. The stem is erect, round, smooth, leafy, usually simple, and from two to six or even eight feet high. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisions. The divisions are wedge-form, with two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniae or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue color, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules, situated on the peduncle within a few lines of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two pediceled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five follicles.

The plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of the plant

by increased salivation, nausea, and wide-spread anæsthesia, due to an action upon the peripheral sensory nerves. If the dose has been sufficient, after the paralysis of sensibility a motor peripheral paralysis comes on, which finally invades the muscles of respiration so that the function ceases, although the heart is still working, and if artificial respiration be employed recovery occurs. The heart is said to be almost completely unaffected, excepting that the force of its contractions is augmented. Intestinal peristalsis is arrested; the pupils are not affected. Elimination is very rapid. Rosendahl asserts that the alkaloid is of great value as a substitute for curare in the physiological laboratory.

Dose, for curarization, per kilogramme of bodily weight: frogs, 0.000174 to 0.0005; dogs, 0.0070; cats, 0.0100; rabbits, 0.003000 to 0.0050; fowls, 0.0090 grammes.

Cynoctonine, $C_{28}H_{45}N_3O_{11}$, is an amorphous hygroscopic grayish powder, having a feebly bitter taste, melting at 137° C.; easily soluble in alcohol and water, soluble in 1373 parts of ether without fluorescence. If evaporated to dryness with fuming nitric acid, the residue becomes blood-red on the addition of an alcoholic solution of potassium hydroxide, afterwards changing to reddish brown. It is a very violent convulsant, producing also vomiting, temporary loss of superficial sensibility, followed by heightened reflexes, violent convulsions, and respiratory death. Upon the heart and blood pressure it has very little influence. The pupils are in the advanced poisoning dilated. Cynoctonine, however, does not act as a poison on the lower organisms.

are acrid and poisonous. The leaves and root are used. The leaves should be collected when the flowers begin to appear, or shortly before. After the fruit has formed, they are less efficacious. The root is much more active than the leaves, and an extract from the latter is said to have only one-twentieth of the strength of one made from the former. It should be gathered in autumn or winter after the leaves have fallen, and is not perfect until the second year. It has been mistakenly substituted for horseradish root, as a condiment, with fatal effect. The wild plant is said to be more active than the cultivated. (Schroff.) Procter found the roots of the plant cultivated in this country richer in active alkaloidal principles than the imported roots, having obtained as much as 0.85 per cent. from the former. (*Proc. A. Ph. A.*, 1860.) The studies of P. W. Squire seem to show that in the autumn the root is the most active. So far, however, as concerns the whole plant, the practical difficulty is that the root of *A. paniculatum*, Lam., cannot be distinguished from that of *A. Napellus*, except by taste; so that the custom which seems to prevail of gathering the root about the flowering period is probably well founded. The plant is being cultivated to some extent for medicinal purposes in England, but much of the stock is of doubtful nature, owing to the extraordinary tendency of *A. Napellus* to hybridize with other species and to alter under cultivation. (See *P. J.*, 1889, 645.) For Keller's tests for aconite root and leaves, see *Proc. A. Ph. A.*, 1895, 539.

Aconite root is generally brought into market in packages or bales, either from the continent of Europe or from India. It is of variable quality, some parcels being unobjectionable, while others contain a considerable proportion of inert or defective roots. Among these roots that of *Imperatoria ostruthium* has been especially observed. (*P. J.*, vii. 749.) The best test is the taste; roots should be rejected which have not in a fair degree the characteristic properties in this respect described below, especially the production of the sensation of numbness and tingling on the tongue, lips, and fauces.

Nepaul aconite is composed of elongated, conical, tuberous, or nearly cylindrical roots, 3 to 4 inches long, $\frac{1}{2}$ to $1\frac{1}{2}$ inches in diameter at the base; unbranched; often abruptly broken off below; more or less flattened; shrivelled chiefly in a longitudinal direction, and sparsely marked with the scars of rootlets. *Japanese aconite* has also been largely sold in London. It consists of plump, oblong, or ovoid, dark grayish or blackish tubers, from half an inch to an inch in length, and $\frac{1}{2}$ to $\frac{3}{4}$ of an inch in diameter. Seven varieties of aconite tubers are reported by Langaard to be found in the Japanese drug stores, usually preserved in vinegar or child's urine, or by drying. The botanical source of these aconite roots is not accurately determined, but they are probably, at

least in part, yielded by *A. japonicum*, Thunb., and *A. Fischeri*, Reich., believed by many botanists to be respectively identical with *A. Lycotomum*, Linn., and *A. chinense*, Sieb. Several alkaloids have been separated; of these, *japaconitine* is said to be the most poisonous of the known aconite alkaloids. (See *P. J.*, 1880, 149, 1021.) O. Lezius (*In. Dis.*, Dorpat, 1890) asserts that the active principle of Japanese aconite is true crystallizable aconitine, and in an elaborate study Alfred E. Bradley found the physiological activity of *A. Fischeri* very similar to that of *A. Napellus*. (*Weekly Med. Rev.*, April, 1888.)

Properties.—The fresh leaves have a faint narcotic odor, most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning and acrid, with a feeling of numbness and tingling on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The dried leaves have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green color, and free from mustiness. The root has a feeble earthy odor. Though sweetish at first, it has afterwards the same effect as the leaves upon the mouth and fauces. It shrinks much in drying, and becomes darker, but does not lose its acrimony. Those parcels, whether of leaves or roots, should always be rejected which are destitute of this property. Aconite root is officially described as being "slenderly conical, 4 to 10 Cm. long, 10 to 20 Mm. thick at the crown; occasionally split; longitudinally wrinkled; dark brown and marked with coarse whitish root-scars; fracture short, horny or mealy; internally whitish or light brown; the cambium zone irregular and 5- to 7-angled; odor very slight; taste sweetish, soon becoming acrid and developing a tingling sensation, followed by numbness." *U. S.* "The transverse section exhibits a thick parenchymatous cortex and a large stellate pith with about seven projecting angles; the groups of vessels are small and few in number." *Br.* The seeds also are acrid. The British Pharmacopœia formerly recognized the flowering tops of the Aconite (*Aconiti Folia*). To be effective they should be collected just as the flowers are beginning to expand, at which time they are richest in alkaloid. The dried leaves are stated to contain about 0.3 per cent. and the flower-buds about 0.4 per cent. of aconitine. For an account of the chemistry of aconite, see *Aconitina*, page 86. In the absence of any reliable chemical tests for aconitine E. R. Squibb suggested that a fluidrachm of a highly diluted solution of the various preparations be taken into the anterior part of the mouth (after the latter has been thoroughly rinsed) and held there for one minute by the watch, and then discharged. The peculiar numbing sensation should be experienced within

fifteen minutes, and it should continue for fifteen or thirty minutes. Tested in this way, he found the commercial aconitines, in solution of the strength of $\frac{1}{10}$ grain in 1 fluidrachm of water, to have the following relative strengths: 1 grain of good powdered aconite root is equal to 1 grain of ordinary commercial aconitine, $\frac{1}{2}$ grain of Merck's ordinary aconitine, $\frac{1}{3}$ grain of Merck's pseudaconitine, $\frac{1}{11}$ grain of Duquesnel's crystallized aconitine (really aconitine nitrate). He also found by this approximate method that 1 grain of powdered aconite root was equivalent to 1 minim of fluidextract, $\frac{1}{2}$ grain of alcoholic extract of aconite root, 2.66 minims of U. S. (1890) or 9.31 minims of U. S. (8th Rev.) tincture of aconite root, 8.43 minims of British tincture of the root, 11.8 minims of German tincture of the root, 1.5 minims of Fleming's tincture, 9 grains of powdered aconite leaf, 1.5 grains of alcoholic extract of dried aconite leaf, 1 grain of Allen's English extract of fresh plant, and 72 minims of tincture of aconite leaf. For methods of assaying aconite, see A. R. L. Dohme's paper (*Proc. A. Ph. A.*, 1895, 206); also P. J., 1895, 860; D. C., 1900, 69, 132.

The quality of aconite root is officially determined by the following assay, which was introduced into the U. S. P. (8th Rev.)

Assay of Aconite.—"Aconite, in No. 40 powder, *ten grammes* (10 Gm.), Alcohol, Distilled Water, Ether, Ammonia Water, Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., each, *a sufficient quantity*. Introduce the Aconite into a 200 Cc. Erlenmeyer flask, add 75 Cc. of a mixture of alcohol, 7 parts, and distilled water, 3 parts (by volume), stopper the flask securely, and agitate it at intervals during four hours. After placing a pledget of cotton in the bottom of a small cylindrical glass percolator (25 Mm. in diameter), carefully transfer the contents of the flask to the percolator. When the liquid has all passed through, continue the percolation with more of the same mixture until 150 Cc. of percolate have been obtained. Pour the percolate into a shallow porcelain evaporating dish, and evaporate it to dryness at a temperature not exceeding 60° C. (140° F.). Add 5 Cc. of tenth-normal sulphuric acid V.S., and 10 Cc. of distilled water. When the extract is dissolved, filter the liquid into a separator, washing the dish and filter with about 40 Cc. of distilled water, and add the washings to the separator. Add 25 Cc. of ether and 2 Cc. of ammonia water to the separator, and agitate it for one minute. Draw off the lower layer into a flask, and filter the ether-solution into a beaker. Return the contents of the flask to the separator, add 15 Cc. of ether, and again agitate it for one minute. Draw off the lower layer into the flask, and filter the ether-solution into the beaker. Repeat the shaking out with two other portions of 10 Cc. each of ether. Evaporate the combined ether-

solutions to dryness, and dissolve the residue in 3 Cc. of tenth-normal sulphuric acid V.S. Add to the solution 5 drops of hematoxylin T.S., and then carefully run in fiftieth-normal potassium hydroxide V.S. until a violet color is produced, the transition stages being as follows: first yellow, then green, finally passing into violet. Divide the number of Cc. of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 3 (the 3 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.064, and this product by 10, which will give the percentage of aconitine in the Aconite." U. S.

Uses.—Aconite was well known to the ancients as a powerful poison, but was first employed as a medicine by Baron Störek of Vienna, whose experiments with it were published in the year 1762. In moderate doses, it produces warmth in the stomach and sometimes nausea, general warmth of the body, numbness and tingling in the lips and fingers, muscular weakness, diminished force and frequency of the pulse, and diminished frequency of respiration. From larger doses all these effects are experienced in an increased degree. The numbness and tingling extend over the body; vertigo and dimness of vision occur; the pulse, respiration, and muscular strength are greatly reduced; and a state of general prostration ensues. The effects of remedial doses are felt in twenty or thirty minutes, are at their height in an hour or two, and continue with little abatement from three to five hours. In poisonous doses, besides the characteristic tingling in the mouth and elsewhere, aconite occasions burning heat of the œsophagus and stomach, thirst, violent nausea, vomiting and purging, severe gastric and intestinal spasms, headache, dimness of vision, with contracted or expanded pupils, numbness or paralysis of the limbs, diminished sensibility in general, stiffness or spasm of the muscles, great prostration, pallid countenance, cold extremities, an extremely feeble pulse, and death in a few hours, sometimes preceded by delirium, stupor, or convulsions. All these effects are not experienced in every case; but there is no one of them which has not been recorded as having occurred in one or more instances. The proper treatment of aconite poisoning consists in the maintenance of absolute rest in a position horizontal, or with the head lower than the feet; the evacuation of the stomach by the siphon tube or stomach pump, if free vomiting does not occur, the administration of stimulants, and the use of external heat to keep up the bodily temperature. Whisky or brandy should be given freely in a concentrated form by the mouth and rectum; when the symptoms are very urgent, it may be injected under the skin. The chief reliance in any case, however, must be on the tincture of digitalis aided by strychnine, the two remedies being given hypodermically, but separately, in large doses. Ammonia may be employed carefully. We have known life to

be apparently saved by a fluidrachm of laudanum. Fall of the bodily temperature must be met by external heat.

The symptoms produced by aconite are chiefly due to its action upon the circulation and the nervous system. It is a direct and powerful depressant of the heart, if in sufficient amount completely paralyzing the cardiac muscle. The lowering of the force of the circulation is certainly in large part due to this action; it is probable that it has comparatively little effect upon the vasomotor system. Upon the cerebrum the drug exerts very little if any direct influence. Upon the peripheral sensory nerves it acts as a powerful depressant, thereby causing the characteristic tingling and numbness of aconite poisoning. The influence upon the spinal marrow seems to be less pronounced than that upon the sensory nerves; but, if in sufficient amount, the poison depresses the motor centres of the cord. To this, and not to any effect upon the motor trunks or the muscles, is due the loss of reflex activity and of voluntary power caused by toxic doses.

As an internal remedy, aconite is valuable in *sthenic fever* from any cause; when the condition is *asthenic* it should never be administered. It is also useful in some cases for the purpose of benumbing sensitive nerves: thus, it will sometimes arrest the *vomiting of pregnancy*, and has often been used with excellent results in *rheumatic neuralgia*. To obtain such effects it must be given boldly. Applied locally to a sensitive or painful part, it is very efficient, owing to its being brought in a concentrated state into contact with the irritated nerves. It is a favorite application in *neuralgias*, and will probably achieve good more often than any other narcotic local remedy. Applied to the skin, aconite occasions heat and prickling or tingling, followed by numbness, and, if in contact with a wound, produces its peculiar constitutional effect. Applied to the eye, it causes decided contraction of the pupil. The dose of the extract of the leaves is from half a grain to a grain (0.03 to 0.065 Gm.). The preparation now almost exclusively employed is the tincture of the root, *Tinctura Aconiti*, U. S., the strength of which was decreased from 35 per cent. to 10 per cent. in the U. S. P. (8th Revision). Of this from three to ten minims (0.2 to 0.6 Cc.) may be given every two to four hours until its effects become obvious. It is important to distinguish between the tincture of the leaves formerly official and the much stronger tincture of the root just referred to. Few patients will bear at first more than four minims of the latter. Very properly, we think, the tincture of the leaves was abandoned at the revision of the U. S. P. 1860. Aconite may be used externally in the form of the fluidextract of the root, of an extract mixed with lard, of a plaster or liniment, or of aconitine ointment or oleate. The fluidextract may be applied by means of a little absorbent cotton tied on the end of a stick.

Dose, of aconite root, one half to one grain (0.032 to 0.065 Gm.).

LARD

(ād'eps)

"The prepared internal fat of the abdomen of the hog (*Sus scrofa*, var. *domesticus* Gray), purified by washing, melting, and straining. It should be kept in well-closed vessels impervious to fat, in a cool place." U. S. "The purified fat of the hog, *Sus Scrofa*, Linn." Br.

Axungia Porci, s. *Porcina*, *Axungia*; Prepared Lard, Hog's Lard; *Axonge*, Fr. *Cod.*; *Graisce*, *Graisce de Porc*, *Saindoux*, Fr.; *Adeps Suillus*, P. G.; *Schweinschmalz*, G.; *Grasso sulino*, *Sugna*, *Grasso di Porco*, Lardo, It.; *Grasa de cerdo*, *Manteca de puerco*, Lardo, Sp.

Preparation.—Lard is the prepared fat of the hog. The Br. Pharmacopœia gives a process for its preparation; but in this country it is generally purchased by the druggists already prepared. The adipose matter of the omentum and mesentery, and that around the kidneys, are usually employed, though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all which it must be freed before it is fit for use. For purification, the fat, having been deprived of membranous matter as far as possible by the hand, is cut into pieces, washed with water till the liquor ceases to be colored, and then, after carefully separating the water, it is melted in a copper or iron vessel, over a slow fire, or on the large scale by steam heat. The heat is continued until all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. Care should be taken that the heat be not too great, as otherwise the lard might be partially decomposed, acquire a yellow color, and become acrid. This may be guarded against by using a water bath in melting the lard. The process is completed by straining the liquid through linen, and pouring it into suitable vessels, in which it concretes upon cooling. To render it, however, perfectly free from particles of membrane and tissue, which are often the cause of rancidity and unfit lard for its finer and more permanent uses, Ed. Smith of Torquay, insists on the necessity of filtering the lard through paper, after freeing it from its coarser impurities by straining through linen. By this author it is recommended that the process of purification should be completed by remelting the lard, by means of a water bath, and then carefully filtering it through paper in a warm closet. Lard may be rendered quite inodorous by melting it, when fresh, by means

of a salt water bath, adding a little alum or common salt, continuing the heat till a scum rises, which is to be skimmed off, and, after the lard has concreted, separating the saline matter by washing it thoroughly with water. For a particular account of the process, see *A. J. P.*, xxviii. 176.

The following is the process of the British Pharmacopœia for preparing lard. "From the perfectly fresh fat of the abdomen of the hog remove as much of the external membranes as possible; suspend the fat so that it shall be freely exposed to the air for some hours; cut it into small pieces; reduce these to a uniform mass in which the membranous vesicles are completely broken, by beating in a mortar or by some similar process; put the mass thus produced into a vessel surrounded by warm water; heat to a temperature not exceeding 135° F. (57.2° C.) until the fat has melted and separated from the membranous matter; strain." *Br.* The process of the British Pharm. differs from that formerly used, and is modelled upon the suggestions of Redwood, that the use of water be especially avoided, and that the selected fat be exposed freely to air and light before rendering. (*P. J.*, 1883, p. 364; also *Ephem.*, 1884, p. 504.)

Lard, as offered for sale, often contains common salt, which renders it unfit for pharmaceutical purposes. This may be detected, when the quantity is insufficient to be sensible to the taste, by means of silver nitrate, which will produce a precipitate of silver chloride with water in which the salted lard has been boiled, after cooling and filtration. To free it from this impurity, it may be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated. Lard is sometimes adulterated with water, starch, and a small portion of alum and quicklime, which render it whiter, but unfit for medicinal use. But by far the most common adulteration of lard in recent years is through the use of cotton seed oil. Indeed, some specimens of lard consist almost wholly of mixtures of stearin and cotton seed oil. Lard of this kind can easily be detected by the disagreeable and characteristic odor of cotton seed oil which is evolved when it is heated. For Taylor's method of differentiation, see *Nat. Drug.*, 1892, p. 103. Crookes (*Analyst*, 1893, p. 221) gives the following very delicate modification of Milliau's test. Pure white filtering paper is first moistened with 12 per cent. solution of silver nitrate and held over a small sample of the lard, which is gradually heated in an oil bath to 115.5° C. (240° F.), when, if even less than 1 per cent. of cotton seed oil is present, the paper will turn light brown to nearly black. Pure fresh lard does not affect the paper. Although it is possible at this time (1905) to obtain lard of excellent quality in the American market, if due care is observed (Gordon, *Proc. Pa. Pharm. Assoc.*, 1901, 126), there are many grades of lard to be found in

commerce, designated by the dealers as follows: 1. Neutral (or Kettle) lard. 2. Leaf lard; made by melting the whole flare with steam, followed by pressure. 3. Choice kettle-rendered lard, chiefly from fat from the back of the hog. 4. Prime steam lard, from all the fatty parts of the hog. 5. Butcher's lard, melted on an open fire. 6. Off grade lard, from salt fat. 7. Dead hog grease, from diseased hogs. 8. Brown grease, from the intestines. 9. White grease, from the other parts. 10. Yellow grease, from the waste of packing warehouses. 11. Pig's foot grease, from glue factories. (*Ph. Ztg.* 96, 402.)

Lard from hogs which have been fed with cotton seed meal will not only show the tests for cotton seed oil (Becchi and Halphen tests), but even the presence of physosterin or vegetable cholesterin can be shown (Emmett & Grindley, *J. Am. C. S.*, 1905, 270).

Properties.—Lard is "a soft, white, unctuous solid, having a faint odor free from rancidity, and a bland taste. Insoluble in water; very slightly soluble in alcohol; readily soluble in ether, chloroform, carbon disulphide, or petroleum benzin. Specific gravity: about 0.917 at 25° C. (77° F.), and about 0.904 at 40° C. (104° F.), water at 25° C. (77° F.) taken as the standard. It melts at 38° to 40° C. (100.4° to 104° F.) to a perfectly clear liquid, which is colorless in thin layers and from which an aqueous layer should not separate. Distilled water boiled with Lard should not acquire an alkaline reaction (absence of *alkalies*). A portion of the water, when filtered, acidulated with nitric acid and treated with silver nitrate T.S., should not yield a white precipitate soluble in ammonia water (absence of *chlorides*). If 10 Gm. of Lard be dissolved in chloroform, and the solution mixed with 10 Cc. of alcohol and 1 drop of phenolphthalein T.S., it should not require more than 0.2 Cc. of normal potassium hydroxide V.S. to produce a pink tint after strongly shaking (limit of *free fatty acids*). If 5 Cc. of melted and filtered Lard be, while warm, intimately mixed by agitation in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol, and adding 2 drops of nitric acid), and the mixture then heated for five minutes in a water-bath, the liquid fat should not acquire a reddish or brown color, nor should any dark color be produced at the line of contact of the hot liquids (absence of more than about 5 percent. of *cotton seed fats*). If 2 Cc. of the melted and filtered Lard be mixed in a test-tube with 2 Cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 percent. of sulphur in solution, and the test-tube be immersed to one-third or one-half its depth in boiling salt water, no reddish color should develop in from ten to fifteen minutes (absence of *cotton seed oil* or of *certain other fats*)." *U. S.* It "is neutral to *litmus*; dissolves entirely in *ether*. It should yield no reaction

with the tests for sodium, chlorides, or starch. If a solution of 0.05 gramme of *silver nitrate* in 5 cubic centimetres of *alcohol* (90 per cent.), to which a drop of *nitric acid* has been added, be heated with 5 cubic centimetres of melted Lard on a water-bath for 5 minutes and then vigorously shaken, the fatty layer which separates on standing should not darken in color (absence of cotton-seed oil.) 10 grammes of Lard dissolved in a mixture of equal volumes of *chloroform* and *alcohol* (90 per cent.), two drops of *solution of phenol-phthalein* being added, should not require more than 0.2 cubic centimetre of the *volumetric solution of sodium hydroxide* to produce a permanent red color (limit of acidity)." *Br.* When melted, it readily unites with wax and resins. Like most animal fats and oils, it consists of stearin, palmitin, and olein, its consistence, when pure, depending largely upon the relative proportions of these principles; olein, being the liquid principle, can readily be separated from the other two by subjecting lard in cold weather to strong pressure, when the *olein* (*lard oil*) is pressed out, the solid residue (*stearin*) being used for various purposes, more particularly the manufacture of candles. Olein may also be separated by means of boiling alcohol, which, on cooling, deposits the concrete principles of the lard. Lard oil (see *Oleum Adipis*) is extensively employed for burning in lamps, as a lubricant, and for greasing wool. Vast quantities of it are prepared in Cincinnati, Chicago, and other centres of the pork slaughtering industry. The exports of lard for 1903 amounted to 535,375,757 lbs., and for 1904, to 563,520,159 lbs.

Exposed to the air, lard absorbs oxygen and becomes rancid. It should, therefore, be kept in well closed vessels, or procured fresh when wanted for use. In the rancid state, it irritates the skin, and sometimes exercises an injurious reaction on substances mixed with it. Rancidity in lard and other fats is prevented by digesting them with benzoin or poplar buds, and rancid lard may often be greatly improved by washing it with lime water. (See *Unguenta*.) Lard even when fresh is slightly acid, as was proved by Dieterich. (*A. Pharm.*, 1887.)

Uses.—Lard is emollient, and is occasionally employed by itself in frictions, or in connection with poultices to preserve their soft consistence; but its chief use is, in pharmacy, as an ingredient in the preparation of ointments and cerates.

ADEPS BENZOÏNATUS. *U. S.* (*Br.*)

BENZOÏNATED LARD

(ăd'ěps bēn-zō-j-nă'tūs)

Adeps Benzoatus, *Br.* *P. G.*, Benzoated Lard; Ointment of Benzoin; Unguentum Benzoini, *U. S.* 1870; Axungia Balsamica, s. Benzoinata, s. Benzoata; Axonge (Graisée) benzoïnée (balsamique), *Fr.*; Benzoinirtes Schmalz, Benzoeschmalz, *G.*; Grasso con benzoino, *It.*; Manteca benzoada, Manteca con benjol, *Sp.*

* "Lard, one thousand grammes [or 35 ounces av., 120 grains]; Benzoin, in coarse powder, twenty grammes [or 309 grains]. Add the Benzoin to the Lard and mix thoroughly; then melt the Lard by means of a water-bath, and, stirring frequently, continue the heat for two hours, covering the vessel and not allowing the temperature to rise above 60° C. (140° F.). Lastly, strain the liquid through muslin and stir occasionally while it cools. When Benzoïnated Lard is to be kept or used during warm weather, 5 percent. (or more, if necessary) of the Lard should be replaced by White Wax." *U. S.*

"Lard, 1 pound (Imperial) or 500 grammes; Benzoin, in powder, 210 grains (Imperial) or 15 grammes. Melt the Lard on a water-bath; add the Benzoin; continue the application of heat for two hours, frequently stirring; remove the residue of the Benzoin by straining; stir the Benzoïnated Lard until cold." *Br.* That the balsamic or resinous principles, in certain substances like benzoin, exercise a valuable function in preserving fats has been proved by abundant experience. It has been shown that when made, as originally suggested by Doliber and directed in the *U. S. Pharmacopœia* of 1870, by incorporating the tincture with lard, ointment of benzoin was irritating to the skin in certain diseases; hence the return to the old process of digesting the benzoin in lard, kept at a temperature of 60° C. (140° F.). The present *U. S.* formula does not differ materially from the British. The name "benzoïnated lard" is preferred by the *U. S. Pharmacopœia* to that used by the British Pharmacopœia "benzoated lard" because benzoin is used as a preservative; the word benzoated might imply that a benzoate or benzoic acid is employed. A much pleasanter and more agreeable product is insured by heeding the *U. S.* directions as to limiting the temperature, a high heat volatilizing the odorous principles and communicating an empyreumatic odor. Benzoïnated lard is largely manufactured by several firms in the United States and is usually of excellent quality.

ADEPS LANÆ. *U. S.*, *Br.*

WOOL-FAT

(ăd'ěps lă'næ)

"The purified fat of the wool of sheep (*Ovis aries* Linné), freed from water." *U. S.* "The purified cholesterin-fat of sheep's wool." *Br.*

Anhydrous wool-fat, *E.*; Suint de laine, *Fr.*; Adeps Lanæ anhydricus, *P. G.*; Wollfett, *G.*

Both the United States and the British Pharmacopœias now recognize wool-fat (anhydrous) and hydrous wool-fat.

Preparation.—The wool of sheep contains on the average about 45 per cent. of its weight of fat, which must be removed before the wool can be used in the manufacture of woollen tissues. The crude fat has been termed *œsipus*

and *œsimum*. This fat, to which the name of lanolin has been given, is a mixture of esters of *cholesterin*, $C_{26}H_{43}(OH)$, with the several fatty acids contained in ordinary fats. Darmstaedter and Lifschütz obtained from the alkaline washings of partially saponified wool-fat two unsaturated alcohols, $C_{10}H_{20}O$ and $C_{11}H_{22}O$, both being colorless, odorless, and tasteless powders; *lanolin alcohol*, $C_{12}H_{24}O$, also a colorless, odorless powder, was isolated by G. Marchetti (*Ber. d. Chem. Ges.*, 1895, No. 19); by the action of chromium trioxide the latter is converted into lanolinic acid, $C_{12}H_{22}O_3$, a white, crystalline powder (*P. J.*, 1895, p. 75.). Wool-fat under the name of lanolin was originally recommended by Oscar Liebreich, and may be readily procured from the washings of the wool by a process which has been patented by him, or it may be obtained by treating the wool with petroleum benzin and distilling off the benzin. The objection to the latter process is the difficulty of getting rid of the benzin odor. Liebreich's patented process is as follows. The fresh undecomposed waste liquor or lye is passed through a centrifugal machine, in which the dirt and fat are separated from each other, while the cleansed soap liquor is continually drawn off by means of a pipe and led directly into the vat which serves for the acidulation. The raw lanolin thus obtained is thoroughly kneaded by suitable machinery in cold flowing water until the water which flows off is as clear as the water which flows in. The raw lanolin is then heated with water, whereby it is split up into water and fat. The latter is skimmed off from the surface and cooled, and for further purification it can be treated in the centrifugal machine in a melted condition, or it can be dissolved in ether, ethylated or methylated spirits, or other solvents, and the solution can be separated from the residue by filtration or other means. The solvents can be recovered by treatment in suitable stills. After the fat has been cleaned as above stated, it is thoroughly kneaded with water for a long time, and a perfectly white neutral colorless ointment is obtained. From the deposit in the lowest part of the centrifugal machine a further portion of lanolin can be obtained by stirring the same up with clean or salt water and again treating it in the centrifugal machine, or extracting it, either in a wet or a dry condition, by means of a solvent, after which it is treated as above.

Instead of producing lanolin from wool-washing water it may be obtained from commercial wool-fat by stirring this wool-fat together with water containing sodium carbonate, caustic soda, or an alkali, or a mixture of these to form a thin milky solution, which is treated in the manner above described.

Properties.—Wool-fat is "a light-yellowish, tenacious, unctuous mass, having a slight, peculiar odor. Insoluble in, but miscible with, large quantities of water, sparingly soluble in cold alcohol, more soluble in hot alcohol,

readily soluble in ether and chloroform. Wool-Fat melts at about $40^{\circ} C.$ ($104^{\circ} F.$), and at a higher temperature vaporizes, the vapor igniting and burning with a luminous, sooty flame. The solution of Wool-Fat in chloroform (1 in 50), when poured upon the surface of concentrated sulphuric acid, gradually develops a deep brownish-red color at the line of contact of the layers. When Wool-Fat is incinerated it should leave not more than 0.3 percent. of ash, which should not show an alkaline reaction to litmus paper (freedom from *alkalies*). If 2 Gm. of Wool-Fat be dissolved in 10 Cc. of ether, and 2 drops of phenolphthalein T.S. added, a colorless liquid should be obtained (absence of *free alkalies*), which, on the addition of 1 drop of normal potassium hydroxide V.S., should develop a deep red color (absence of *free fatty acids*). If 1 Gm. of Wool-Fat be boiled with 20 Cc. of alcohol, and the solution filtered after cooling, the filtrate should not be rendered turbid by the addition of an alcoholic solution of silver nitrate (1 in 20) (absence of *chlorides*). If 10 Gm. of Wool-Fat be heated with 50 Cc. of water on a bath of boiling water until completely fused, the lower aqueous layer, when filtered through a well-wetted filter, should not yield *glycerin* on evaporation, and when boiled with potassium hydroxide T.S. it should not give off vapors of ammonia (absence of *organic nitrogenous matter*)." *U. S.* "A yellowish, tenacious unctuous substance; almost inodorous; melting point varies from 104° to $112^{\circ} F.$ (40° to $44.4^{\circ} C.$); readily soluble in *ether* or in *chloroform*, sparingly soluble in *alcohol* (90 per cent.). 1 gramme should dissolve almost completely in 75 cubic centimetres of boiling *alcohol* (90 per cent.), the greater part separating in flocks on cooling. When incinerated with free access of air, it leaves not more than 0.3 per cent. of ash, which should not be alkaline to *litmus*. 10 grammes dissolved in 25 cubic centimetres of *ether*, two drops of *solution of phenol-phthalein* being added, should not require more than 0.1 cubic centimetre of *volumetric solution of sodium hydroxide* to produce a permanent red coloration (limit of acidity). The solution in *chloroform* poured gently over the surface of *sulphuric acid* acquires a purple-red color. Heated with *solution of sodium hydroxide*, no ammoniacal odor should be evolved (absence of nitrogenous animal matter)." *Br.*

Off. Prep.—Adeps Lanæ Hydrosus, *Br.*

ADEPS LANÆ HYDROSUS. U. S., Br.

HYDROUS WOOL-FAT

(ād'eps lā'næ hŷ-drō'sus)

"The purified fat of the wool of sheep (*Ovis aries* Linné), mixed with not more than 30 percent. of water." *U. S.*

Lanoline; Lanolin, Adeps lanæ cum aqua, *P. G.*; Wasserhaltiges Wollfett, *G.*; Lanolina, *It., Sp.*

"Wool Fat, 7 ounces (Imperial) or 140 grammes; Distilled Water, 3 fl. ounces (Imp. meas.) or 60 cubic centimetres. Place the Wool Fat in a warm mortar; add the Distilled Water gradually and with constant trituration." *Br.*

Properties.—Hydrous wool-fat is officially described as "a yellowish-white, or nearly white, ointment-like mass, having a slight, peculiar odor. Insoluble in water, but miscible with twice its weight of the latter, without losing its ointment-like character. With ether or chloroform it yields turbid solutions which are neutral to moistened litmus paper. Hydrous Wool-Fat melts at about 40° C. (104° F.), and separates into an upper oily and a lower aqueous layer. When heated on a water-bath, with stirring until it ceases to lose weight, there should remain not less than 70 percent. of a residue, which is transparent when melted, and when cold remains as a yellowish, tenacious, unctuous mass, completely soluble in ether or chloroform, and only sparingly soluble in alcohol. If Hydrous Wool-Fat be thus deprived of water, it should respond to the tests given under *Adeps Lanæ*." *U. S.* "10 grammes heated on a water-bath, with stirring, until the weight is constant, should yield not less than 7 grammes of residue, which should answer to the tests for Wool Fat." *Br.*

Uses.—It has been claimed for hydrous wool-fat that it passes through the skin much more readily than do ordinary fatty substances. According to Patschkowski, half an hour after inunction of a mixture of lanolin and potassium iodide, iodine can be recovered from the urine, while the official ointment yields a negative result. This has been confirmed by Kaspar; but Ritter and Pfeiffer in a long series of experiments were unable to perceive that hydrous wool-fat had any superiority over other fats in promoting absorption. Further, when it is remembered that it is a sebaceous secretion, largely composed of cholesterolin and allied substances, and not intended by nature to be absorbed, but to grease and soften the fibres of the wool, the possession by it of the property of aiding absorption through the skin becomes very doubtful. On the other hand, it is undoubtedly soothing to the skin, and often makes an excellent vehicle for ointments intended to act especially upon the skin. It has been used in suppositories, bougies, and plasters as a vehicle and is an ingredient in six official ointments and a plaster.

ÆTHER. U. S. (*Br.*)

ETHER [*Stronger Ether*]

(æ'ther)

"A liquid composed of about 96 percent., by weight, of absolute Ether or Ethyl Oxide [$(C_2H_5)_2O = 73.52$], and about 4 percent. of alcohol containing a little water. Ether should be kept in partially filled, well-stoppered containers,

preferably tin cans, in a cool place, remote from lights or fire." *U. S.* "A volatile liquid prepared from ethylic alcohol by interaction with sulphuric acid. It contains not less than 92 per cent. by volume of ethyl oxide ($C_2H_5)_2O$." *Br.* *Purified Ether* is defined as "Ether from which most of the ethylic alcohol has been removed by washing with distilled water, and most of the water by subsequent distillation in the presence of calcium chloride and recently prepared lime." *Br.*

Æther Purificatus. *Br.* Purified Ether; Æther sulphuricus, *Ed., Dub.*; Ether, Hydric Ether, Sulphuric Ether, Naphtha Vitrioli, Hydrate of Ethylen, Oxide of Ethyl; Ether officinal, Ether pur, *Fr. Cod.*; Ether, Ether hydrique, ou vinique, ou sulfurique, *Fr.*; Aether, *P. G.*; Reiner Aether, Schwefeläther, *G.*; Etere, *It.*; Eter, Eter sulfurico, *Sp.*

The U. S. Pharmacopœia of 1880 recognized Æther containing about 74 per cent. of ethyl oxide and Æther Fortior containing about 94 per cent. of ethyl oxide. The present Æther of the U. S. Pharmacopœia replaces the Æther Fortior of the U. S. P. 1880, the Æther of the U. S. P. 1880 being dropped, as its deficient strength rendered it of little use. The Æther Purificatus of the British Pharmacopœia and the Æther of the U. S. Pharmacopœia (8th Rev.) are practically identical in strength. The British purified ether, on account of its having the alcohol removed by washing with water, is sometimes termed *Æther Lotum*, or washed ether. It still contains a trace of water.

Preparation.—A process for preparing ether upon the small scale was given in the U. S. P. 1870, and a former British Pharmacopœia, see U. S. D., 18th ed. p. 118, but it was properly abandoned by both Pharmacopœias, as the production of this inflammable and very volatile liquid should be undertaken only in buildings properly safeguarded, and it is now made of excellent quality on a large scale with special apparatus. Ether was made officially by the action of sulphuric acid upon alcohol, in a glass flask, at a temperature ranging between 130° C. (266° F.) and 137.7° C. (280° F.), the distillate being afterwards rectified to remove impurities.

In the apparatus employed by E. R. Squibb the ether is made in one operation; the vapors of ether and unchanged alcohol are first washed by a solution of caustic potash maintained at a temperature above the boiling point of alcohol, the alcoholic vapor is then condensed in a worm kept at a suitable temperature and runs back into the still, while the ether vapor, retaining about 4 per cent. of alcohol, is condensed in a well cooled apparatus. 360 lbs. of concentrated sulphuric acid are sufficient to etherify 120 barrels of clean spirit; the acid has then to be changed, chiefly because the impurities of the spirit render the mixture dark and tarry and liable to froth in the still. (*Ephem.*, ii. p. 590.) Kraft proposes to manufacture ether by heating alcohol in contact with the alkyl esters of sulphonic acid. He states that benzene-sul-

phonic acid under favorable conditions is capable of converting several thousand times its weight of alcohol into ether. The advantage claimed for this method is greater purity of the resulting ether. (*Chem. Ztg.*, 1893, 1876.) Ekenberg purifies ether by mixing it with 5 or 10 per cent. of liquid paraffin, which has a boiling point of about 300° C., and distilling at a temperature of from 40° to 50° C. The liquid paraffin holds the impurities and permits the pure ether to distil over. (*Chem. Ztg.*, 1894, 1240.)

Properties of Ether.—In considering the properties of ether it is necessary to draw a sharp distinction between the official ethers of the two Pharmacopœias. The term Ether (*Æther*) is used now (1905) for the second grade ether (sp. gr. 0.735) of the British Pharmacopœia as well as for the only ether now recognized by the U. S. Pharmacopœia [sp. gr. 0.716 to 0.717 at 25° C. (77° F.)]; this latter corresponds with the Purified Ether (*Æther Purificatus*) of the British Pharmacopœia, which has the sp. gr. 0.720 at 15.6° C. (60° F.). Ether of the U. S. Pharmacopœia (8th Rev.) is described as follows. "A transparent, colorless, mobile liquid, having a characteristic odor, and a burning and sweetish taste. Specific gravity: 0.716 to 0.717 at 25° C. (77° F.). Soluble in about 10 times its volume of water at 25° C. (77° F.), with slight contraction of volume. Miscible, in all proportions, with alcohol, chloroform, petroleum benzin, benzene, fixed and volatile oils. Ether boils at about 35.5° C. (96° F.), and it should, therefore, boil when a test-tube, containing some broken glass and half filled with it, is held for some time closely grasped in the hand. Ether is highly volatile and inflammable. Its vapor, when mixed with air and ignited, explodes violently. The color of light blue litmus paper moistened with water should not be changed to red when the paper is immersed in Ether for ten minutes. Upon evaporation, Ether should leave *no residue*. If 10 Cc. of it be poured, in portions, upon clean, odorless blotting paper, and allowed to evaporate spontaneously, *no foreign odor* should become perceptible when the last traces of Ether leave the paper. When 20 Cc. of Ether are shaken, in a graduated tube, with 20 Cc. of water, just previously saturated with Ether, the ether-layer, upon separation, should measure not less than 19.2 Cc. (absence of an *undue amount of alcohol or water*). If 10 Cc. of Ether be shaken occasionally, during one hour, with 1 Cc. of potassium hydroxide T.S., no color should be developed in either liquid (absence of *aldehyde*)." U. S. The British Pharmacopœia gives the following tests for purified ether. "Specific gravity not exceeding 0.722 and not below 0.720. 5 cubic centimetres on spontaneous evaporation should not afford any abnormal odor and should not leave any residue. Its vapor is heavy and highly inflammable. It should dissolve in an equal volume of carbon

bisulphide (absence of excess of water). Heated, it begins to distil at a temperature not under 94.1° F. (34.5° C.) (absence of methylic ether). No effect should be produced by the addition of *potassium hydroxide* (absence of aldehyde). No alteration in color is produced on moistened *blue litmus paper* after twenty-four hours' contact (absence of acid). On shaking with half its bulk of a diluted solution of *potassium bichromate* acidulated with *sulphuric acid*, and setting aside, the supernatant Ether should have no blue color (absence of hydrogen peroxide). Filter-paper moistened with Purified Ether should remain odorless when the liquid has evaporated." Br.

Commercial ether, which is sometimes used as a solvent, varies in sp. gr. from 0.733 to 0.765. The impurities found in it are excess of alcohol, water, sulphurous and other acids, heavy oil of wine, and various fixed substances.

The ether of U. S. P. 1880 should have the sp. gr. 0.750; if heavier than this, it must contain too much alcohol or water. The statement that water takes up only one-tenth of ether, when equal volumes of ether (sp. gr. 0.750) and water are shaken together in a graduated tube, has been shown by Squibb to be erroneous. If it take up more than one-fourth, the ether must contain an excess of alcohol or water, or of both. If the alcohol be in excess, it may be removed by agitating the liquid with twice its bulk of water, which unites with the alcohol, forming a heavier stratum, from which the ether may be poured off. The ether, however, takes up about one-tenth of water, which may be removed by agitation with freshly burned lime, and subsequent distillation. An easy method for detecting and measuring any alcohol present in ether was given by the Edinburgh College; namely, to agitate it, in a graduated cylinder, with half its volume of a concentrated solution of calcium chloride. This will remove the alcohol and the reduction of the volume of the ether, when it rises to the surface, will indicate the amount. The official test is based upon this old method; the use of water saturated with ether is, however, an improvement over the use of a solution of calcium chloride. Heavy oil of wine may be discovered by the ether becoming milky upon being mixed with water. If the ether be pure, it wholly evaporates in the air, leaving no solid residue. All non-volatile impurities are thus detected. The point of ebullition is also an indication of the strength of the ether. When evaporating from bibulous paper, it should offer only a slight degree of foreign odor, aromatic and free from pungency, and should leave the paper, when dry, nearly or quite odorless. This test proves the absence of volatile impurities, except a slight and not inadmissible proportion of light oil of wine.

The tests for the British ether are as follows: "100 volumes agitated with an equal volume of water should not be reduced to less than 90 (absence of excess of ethylic alcohol). It should boil below 105° F. (40.5° C.). Spe-

cific gravity 0.735. It evaporates without residue. It should have no action on *solution of litmus*. It should dissolve without coloration when introduced drop by drop into *sulphuric acid* kept cool during the test (absence of organic impurities)." *Br.* This commercial ether may answer for external application, and may even be given by the mouth, but for purposes of inhalation it is entirely unfitted without further purification.

The extreme volatility of ether causes it to evaporate speedily in the open air, with the production of considerable cold. Its inflammability is very great, and the products of its combustion are water and carbon dioxide. In consequence of this property the greatest care should be used not to bring it in the vicinity of flame, as, for example, a lighted candle. One of the great advantages of using steam as the source of heat is that it obviates, in a great measure, the danger of its accidental inflammation. When too long kept it undergoes decomposition, and is converted in part into acetic acid. It dissolves iodine and bromine freely, and sulphur and phosphorus sparingly. Its power to dissolve corrosive sublimate makes it a useful agent in the manipulations for detecting that poison. It is also a solvent of volatile and fixed oils, many resins and balsams, tannic acid, caoutchouc, and most of the organic vegetable alkaloids. It does not dissolve potassium or sodium hydroxide, in which respect it differs from alcohol. Ether unites in all proportions with alcohol. According to R. Boettger, water may be detected in ether by agitating the suspected liquid with carbon disulphide; if water be present the mixture becomes milky and turbid, otherwise it remains clear. Stefanelli (*Ber. d. Chem. Ges.*, 8, 439) proposed to shake ether with a small fragment of aniline-violet, which does not impart color to ether free from alcohol. One per cent. of alcohol may be thus detected. Ether is usually made anhydrous by allowing it to remain in contact with dry calcium chloride or by distilling it with a small quantity of metallic sodium in a flask or retort.

The most delicate test for the presence of alcohol in ether is that of Lieben, founded on the formation of iodoform by alcohol but not by ether. (See p. 105.) The mere keeping of ether in the presence of moisture is said to generate sufficient alcohol to produce the reaction. (Allen, *Com. Org. Anal.*, 2d. ed., i. p. 125.)

On filtering an ethereal liquid with free access of air, a frost-like congelation is observed on the upper part of the filter, its appearance and quantity depending upon the temperature and the hygrometric state of the atmosphere. Tanret has collected some of this *ether hydropoxide*, and found that after it had been completely freed from ether by strongly blowing upon it, it had the temperature -3.5°C . (25.7°F .), and on fusion yielded 17 to 18 parts of water for 37 of ether; the formula $(\text{C}_2\text{H}_5)_2\text{O}$, $2\text{H}_2\text{O}$ requires 18 parts. (*A. J. P.*, 1878.)

Composition and Theory of its Production.—The empirical formula of ether is $\text{C}_4\text{H}_{10}\text{O}$, and this is the result both of analysis and of a determination of its vapor density, whereby the molecular weight is established. This formula, however, is better understood when we examine the conditions of its formation. Ether is then found to be the oxide of ethyl (C_2H_5). This is the group which gives character to common alcohol and all its salts, whether with organic or inorganic acids. The group C_2H_5 acts as a monad radical, and common alcohol is its hydroxide, $\text{C}_2\text{H}_5\text{OH}$. Its oxide then should be $(\text{C}_2\text{H}_5)_2\text{O}$, and all the reactions by which ether is produced show it to be this oxide. It is commonly formed from common alcohol (ethyl hydroxide) by the action of sulphuric acid, according to the following reactions:

that is, alcohol reacting with sulphuric acid yields ethyl-sulphuric acid (sulphovinic acid) and water. In the presence of an excess of alcohol and at the proper temperature the ethyl-sulphuric acid then reacts with another molecule of alcohol, as follows:

whereby ethyl oxide (ether) is formed, and sulphuric acid is regenerated. These reactions take place best at a temperature of about 140°C . (284°F .), and if the mixture in the still is kept at this temperature a steady stream of alcohol can be converted into ether, whence the process has been called "the continuous etherification process."

Uses.—As early as 1805, inhalations of ether were recommended by Warren of Boston, to relieve pulmonary distress in advanced *phthisis*, and in 1812 ether intoxication by inhalation was said to have been frequently practiced in Philadelphia, but it was not until October, 1846, that Warren, at the instance of W. T. G. Morton of Boston, used ether as a surgical anæsthetic at the Massachusetts General Hospital. A few days subsequently, C. T. Jackson of Boston, claimed to have first made known to Morton the use of ether for the prevention of pain in dental operations.

Locally, ether is a violent irritant. It is absorbed through the lungs with very great rapidity, and less quickly but with equal certainty through the mucous membrane of the gastro-intestinal tract, and is eliminated by the lungs and kidneys. Its first action upon the circulation is to raise the arterial pressure by increasing the output of work from the heart, and probably also by stimulating the vasomotor centres and bringing about contraction of the blood vessels. The large dose finally depresses both the heart and the vasomotor system. In full dose it acts as a depressant to the ganglionic cells or to the nerve centres, paralyzing the cerebral cortex so as to produce loss of consciousness; lessening the activity of the spinal cord, so as to cause loss of sensi-

bility, muscular relaxation, and paralysis of the reflexes. Rarely the loss of sensibility precedes the loss of consciousness, showing that the loss of sensibility is not simply due to the suspension of consciousness. In the great majority of cases when ether produces death either in man or in the lower animals, the fatal result is caused by a central paralysis of respiration; in very rare instances, however, sudden cardiac arrest has occurred during etherization both in man and in animals.

As a practical anæsthetic, ether is inferior to chloroform in being distinctly slower in action, more disagreeable to the patient by producing greater excitement and in being more apt to cause prolonged nausea and vomiting after use. Statistics show, however, that the proportion of deaths due to chloroformization is four to five times greater than after etherization; and only in rare circumstances is the surgeon justified for the sake of convenience in selecting the more dangerous anæsthetic.

It being impossible in the space which can be allotted to the subject in the present work to discuss to any advantage the subject of etherization, either in its general, theoretical, or practical aspects, the reader is referred to works on practical anæsthesia and to text books on therapeutics.

Given by the mouth, ether may be used in nausea dependent upon gastric depression, in excessive flatulence especially when attended by colic, and in *gastrodynia*. It has also been administered in the treatment for *gall stones* with the belief, probably not well founded, that it would aid in the solution of the stones. As a constituent of Hoffmann's anodyne it is much used as a stimulant antispasmodic. For administration by the mouth it is best given floating on ice-cold water, though it is sometimes administered in capsules under the name of *pearls*, and a syrup of ether is recognized by the French Codex. According to Regnault and Adrian, the best syrup of ether is to be made by shaking together in a bottle 440 parts of sugar, 490 parts of distilled water, 50 parts of alcohol (sp. gr. 0.833), 20 parts of ether. If the parts taken are represented by grains the formula would give one full dose of the narcotic.

Dose, half to one fluidrachm (1.8 to 3.75 Cc.).

ÆTHER ACETICUS. *U. S., Br.*

ACETIC ETHER [Ethyl Acetate]

(æ'ther a-cët'i-cûs)

Naphtha Aceti; Ethyl Acetate; Ether acétique, Acétate d'éthyl, *Fr. Cod.*; Naphte acétique, *Fr.* Æther aceticus, *P. G.*; Essigäther, Essignaphtha, *G.*; Etere acetico, *It.*; Eter acetico, *Sp.*

"A liquid composed of about 90 percent., by weight, of Ethyl Acetate [$\text{CH}_3\text{CO.OC}_2\text{H}_5 = 87.40$], and about 10 percent. of alcohol containing a little water. It should be kept in well-stoppered bottles, in a cool and dark place, remote from lights or fire." *U. S.* "An ethereal liquid consisting of ethyl acetate, $\text{CH}_3\text{COO}(\text{C}_2\text{H}_5)$, together with unimportant amounts of ethylic alcohol or other substances, obtained by distillation from a mixture of ethylic alcohol, sulphuric acid, and dried sodium acetate, digestion of the distillate with dried potassium carbonate, and subsequent separation, by distillation, of the portion boiling between 165° and 172° F. (73.9° and 77.8° C.)." *Br.*

Preparation.—A process for preparing this ether will be found in a former British Pharmacopœia (1885). It is a modification of the process recommended by W. I. Clark (*P. J.*, 1883, p. 777), and is as follows: "Take of Rectified Spirit, $32\frac{1}{2}$ fluidounces [Imp. meas.]; Sulphuric Acid, $32\frac{1}{2}$ fluidounces [Imp. meas.]; Acetate of Sodium, 40 ounces [av.]; Carbonate of Potassium, freshly dried, 6 ounces [av.]. To the spirit slowly add the acid, keeping the fluid cool, and, the product being cold, add the acetate, mixing thoroughly. Distil forty-five fluidounces [Imp. meas.]. Digest the distillate with the carbonate of potassium for three days in a stoppered bottle. Separate the ethereal fluid, and again distil until all but about four fluidounces have passed over. Preserve the resulting acetic ether in a well-closed bottle and in a cool place." *Br.* 1885. In addition to this method, acetic ether may be made by several processes, the chief of which are the following: 1. Mix 100 parts of alcohol (sp. gr. 0.83) with 63 parts of concentrated acetic acid, and 17 parts of strong sulphuric acid, and distil 125 parts into a well cooled receiver. 2. Distil to dryness a mixture of three parts of sodium acetate, three of alcohol, and two of sulphuric acid, mix the distilled product with one-fifth of sulphuric acid, and distil a second time an amount of ether equal to the alcohol employed. 3. Distil two parts of efflorescent lead acetate with one part of alcohol and a little more than one part of sulphuric acid. In the last two processes, the acetic acid is set free by the action of the sulphuric acid on the acetate employed. J. A. Pabst has devised a process for acetic ether in imitation of that for the preparation of common ether. 50 Cc. of sulphuric acid and the same quantity of alcohol are heated together in a retort to 140° C. (284° F.), and then a mixture of one liter of 96 per cent. alcohol and one liter of acetic acid (93 per cent.) is allowed to flow in slowly. At first some ethyl ether goes over, and then a liquid which contains, with considerable uniformity, 85 per cent. acetic ether. The reaction takes place between 130° C. (266° F.) and 135° C. (275° F.); at 145° C. (293° F.) some sulphurous acid is produced. The yield is about 1350 grammes, or 78 per cent., which is 90 per cent. of the theoretical amount. With

reference to the solubility of acetic ether in saturated calcium chloride solution, it is to be remarked that pure acetic ether is not dissolved, except when it is mixed with 90 per cent. alcohol. One volume acetic ether, one volume alcohol, and two volumes calcium chloride solution give a homogeneous liquid. The methyl acetic ether can be prepared exactly as the ethyl compound, but in the attempt to prepare the amyl acetic ether, in an analogous manner, side reactions were found to interfere. In order to study the proportional power of combination possessed by the two alcohols, Pabst allowed a mixture of 100 Cc. methyl alcohol and 100 Cc. acetic acid to flow into a mixture of 50 Cc. sulphuric acid and 50 Cc. ethyl alcohol. The first distillates contained essentially methyl acetate and the latter pure ethyl acetate. In the flask were found remaining nearly equal amounts of sulphuric and ethyl-sulphuric acids, and in addition alcohol, acetic acid, and some residual ethyl acetate. (*Bull. Soc. Chim.*, vol. xxxiii. pp. 350, 351; *A. J. P.*, 1880.)

Properties.—The U. S. Pharmacopœia describes it as “a transparent, colorless liquid, of a fragrant and refreshing, slightly acetous odor, and a peculiar acetous and burning taste. Specific gravity: 0.883 to 0.885 at 25° C. (77° F.). Soluble in about 7 parts of water at 25° C. (77° F.); miscible, in all proportions, with alcohol, ether, fixed and volatile oils. Boiling point: about 72° C. (161.6° F.). Acetic Ether is readily volatilized, even at a low temperature. It is inflammable, burning with a yellowish flame and an acetous odor. It should not immediately redden blue litmus paper. Upon evaporation, Acetic Ether should leave no residue. If a portion be allowed to evaporate spontaneously from clean, odorless blotting paper, the final odor should not resemble that of pineapple (absence of *butylic* and *amylic* derivatives). When 25 Cc. of Acetic Ether are shaken, in a graduated tube, with 25 Cc. of water just previously saturated with Acetic Ether, upon separation the ethereal layer should not measure less than 22.5 Cc. (absence of an *undue proportion of alcohol or water*). When a small portion of Acetic Ether is carefully poured upon concentrated sulphuric acid, no dark ring should be developed at the point of contact of the two layers (absence of *readily carbonizable, organic impurities*).” *U. S.* “1 part by weight dissolves in not less than 10 parts of cold water. Specific gravity 0.900 to 0.905. It should have no action on *solution of litmus*. It is not colored when mixed with an equal volume of *sulphuric acid* (absence of organic impurities). Filter-paper moistened with Acetic Ether should remain odorless when the liquid has evaporated.” *Br.*

Uses.—Acetic ether is occasionally used in medicine as a stimulant and antispasmodic. Its action upon the system is probably very similar to that of ether; but as it is less volatile it is less rapidly absorbed and eliminated, and consequently is much less prompt and fugacious

in its influence than is ether. It is locally irritating. H. C. Wood found it to be capable of being used as an anæsthetic, but to be too slow in its action for practical purposes. It is sometimes employed externally, by friction, as a resolvent, and for *rheumatic pains*.

Dose, fifteen to fifty minims (0.9 to 3.1 Cc.).

Off. Prep.—Liquor Epispasticus, *Br.*

ÆTHYLIS CARBAMAS. U. S.

ETHYL CARBAMATE

(æ'thyl-is cār'ba-mās)

$C_2H_7NO_2 = 88.42$

“An ester of carbamic acid [$CO(OC_2H_5)N H_2$] obtained by the reaction of ethyl alcohol upon urea (carbamide) or one of its salts. It should be kept in well-stoppered bottles.” *U. S.*

Ethyl urethane, Urethane; Uréthane, *Fr.*; Carbaminsäureæthylester, Äethyl-urethan, Urethan, *G.*; Uretano, Eter Carbamico, *Sp.*

Ethyl carbamate was introduced into the U. S. Pharmacopœia (8th Rev.) and is made by allowing ammonia to act upon ethyl carbonate, when urethane and ethyl alcohol are produced, or by heating urea nitrate with alcohol to from 120° to 130° C., resulting in the formation of ethyl carbamate and ammonium nitrate.

Properties.—It is officially described as in “colorless, columnar crystals or scales, odorless, and having a cooling, saline taste. Soluble in less than 1 part of water, 0.6 part of alcohol, 1 part of ether, 1.3 parts of chloroform, and 3 parts of glycerin, at 25° C. (77° F.). When heated between 47.5° and 50° C. (117.5° and 122° F.) it melts, and at a higher temperature is decomposed, burning without leaving a weighable residue. If 1 Gm. of Ethyl Carbamate be added to 5 Gm. of sulphuric acid and gently heated, it is decomposed with the evolution of carbon dioxide, while alcohol and acid ammonium sulphate remain in solution. If 1 Gm. of Ethyl Carbamate be heated with 5 Cc. of concentrated potassium hydroxide solution, ammonia gas is given off, recognizable by the usual tests. If 0.5 Gm. of Ethyl Carbamate be dissolved in 5 Cc. of water with 1 Gm. of dry sodium carbonate and 0.01 Gm. of iodine, and the solution warmed, yellow crystals of iodoform should separate on cooling. If 6 Gm. of Ethyl Carbamate be dissolved in 6 Cc. of water, and the solution be divided into 3 equal parts, the addition severally of 5 Cc. of nitric acid, of mercuric nitrate T.S., or of oxalic acid T.S. should not produce a white precipitate (distinction from, and absence of, *urea or carbamide*).” *U. S.* When it is heated with ammonia to 180° C., urea is formed.

Uses.—Urethane produces in the lower animals a brief period of excitement, which is followed by deep sleep, with slowing of the respiration. If a fatal dose has been taken, the respiration becomes slower, the unconsciousness absolute, the reflexes are abolished, and a

pronounced fall of bodily temperature occurs, with marked weakness of the cardiac action, and finally death from asphyxia. In therapeutic doses it is depressant to the brain and spinal cord but has practically no effect on the circulation. The psychomotor centres in the cerebral cortex, according to von Anrep, suffer decrease of faradic excitability under the influence of decided doses. Urethane has been largely used as a hypnotic and in the milder forms of *insomnia* is often a useful remedy on account of its safety. In severe cases it is, however, uncertain in its effect. It has been used by Jackman and others (*L. L.*, June, 1886) in *traumatic tetanus* and other convulsions, as *puerperal eclampsia*, with success.

Dose, as somnifacient, fifteen to forty-five grains (1 to 3 Gm.); in tetanus seventy-five grains (5 Gm.) may be given as a dose.

ÆTHYLIS CHLORIDUM. U. S.

ETHYL CHLORIDE

(æ'thyl-is chlô'rî-dûm)

"A haloid derivative [Monochlor-Ethane, $C_2H_5Cl = 64.00$], prepared by the action of hydrochloric acid gas upon absolute ethyl alcohol. On account of its extreme volatility, it should be preserved in hermetically sealed glass tubes, and kept in a cool place, remote from lights or fire." *U. S.*

Hydrochloric ether; Chlorethyl. Monochlorethane; Ethylum chloratum, Ether chloratus; Chlorure d'ethyl, Ether hydrochlorique, *Fr.*; Aethylchlorid, Chlorwasserstoffäther, Chloraethyl, *Gr.*

Preparation.—This ether was discovered by Rouelle, but first obtained in sufficient quantities to permit the examination of its properties by Basse. It may be procured by several processes, but the following is the best. Distil a mixture of equal measures of concentrated hydrochloric acid and alcohol, and receive the product, by means of a curved glass tube, in a tubulated bottle, half filled with water at a temperature between $21.1^{\circ} C.$ ($70^{\circ} F.$) and $26.6^{\circ} C.$ ($80^{\circ} F.$), and connected by means of a second tube with another bottle, loosely corked, and surrounded by a mixture of common salt with snow or pounded ice. The ether, as it enters the first bottle, is mixed with alcohol and acid, which are retained by the water; while the pure ether passes forward, and is condensed in the refrigerated bottle. It must be kept in strong bottles, well secured with ground stoppers covered with leather. Before being opened, the bottle should be cooled to the freezing point.

Properties.—Ethyl chloride is a colorless liquid, having a strong, slightly saccharine, alliaceous taste, and a penetrating, ethereal, alliaceous odor. Its sp. gr. at the temperature of $0^{\circ} C.$ ($32^{\circ} F.$) is 0.9214. It is extremely volatile, entering into ebullition at $10^{\circ} C.$ ($50^{\circ} F.$), so that in summer it may be collected in the gaseous state, in bell glasses over water.

Its sp. gr. in the state of vapor is 2.22. When kindled as issuing from a fine orifice, it burns with an emerald-green flame, without smoke, diffusing a strong odor of hydrochloric acid; but, when set on fire in quantities, it burns with a greenish-yellow, smoky flame. Water dissolves one-fiftieth of its weight of this ether, and acquires a sweetish, ethereal taste; and alcohol unites with it in all proportions. These solutions are not precipitated by silver nitrate, showing that the chlorine present is in a peculiar state of combination. Like common ether and ethyl nitrite, it dissolves sulphur, phosphorus, the fixed and volatile oils, and many other substances. It consists of one atom of chlorine combined with the monatomic radical or group C_2H_5 , *ethyl*, and its composition is sufficiently shown by the reaction for its production:

It is officially described as "a colorless, mobile, very volatile liquid, having a characteristic, rather agreeable odor, and a burning taste. Specific gravity: 0.918 at $8^{\circ} C.$ ($46.4^{\circ} F.$). Ethyl Chloride is slightly soluble in water, readily soluble in alcohol. It boils at a temperature of 12.5° to $13^{\circ} C.$ (54.5° to $55.4^{\circ} F.$), and at its ignition temperature burns with a smoky, green-edged flame, with the production of gaseous hydrochloric acid. When liberated, at ordinary room-temperatures, from its sealed glass tube, Ethyl Chloride vaporizes at once; the gas is very inflammable, and consequently it should not be used in proximity to a gas-flame or fire. If 10 Ce. of Ethyl Chloride, while cold, be dissolved in alcohol, and a few drops of silver nitrate T.S. be added, no turbidity should be produced (absence of *hydrochloric acid*). If 10 Ce. of Ethyl Chloride be agitated with 10 Ce. of cold water, and the supernatant stratum of Ethyl Chloride be evaporated spontaneously, and if a few drops of potassium dichromate T.S. be added to the remaining aqueous liquid, followed by some diluted sulphuric acid, and the mixture be boiled, no odor of aldehyde should be developed, and a greenish or purplish color should not be produced in the liquid (absence of *alcohol*). On allowing Ethyl Chloride to evaporate from clean, odorless blotting paper which has been saturated with it, no unpleasant odor should remain upon the paper (absence of *sulphur compounds*, etc.)." *U. S.*

Owing to its extreme volatility, it cannot be kept readily. It may, however, be preserved in a cool cellar, the temperature of which does not rise above $7.2^{\circ} C.$ ($45^{\circ} F.$) or $10^{\circ} C.$ ($50^{\circ} F.$), being well secured in bottles, which should be stored in a reversed position.

Uses.—Ethyl chloride has been used in practical medicine as a method of producing local anæsthesia by freezing, and internally as a general anæsthetic. As an anæsthetic its action is extremely rapid and fugacious. Its action upon the circulation is similar to but less imperious than that of chloroform, the arterial pressure being lessened by depression of the

heart. It appears to be safer than chloroform, Ware having recorded over 11,000 cases of its use with but one death. Advantage has been taken of the great volatility of ethyl chloride for practical use as a local anæsthetic by freezing. It is now furnished for dental and other use, in hermetically sealed tubes, so made that when the end is broken off, and the tube held in the hand, the liquid comes out in a fine stream which may be directed upon the part to be frozen. H. C. Wood and David Cerna (*Dental Cosmos*, 1892) find that ethyl chloride taken into the blood acts very much like chloroform. On account of its great inflammability it should not be used near a light or flame. *Alcoholic muriatic ether*, or a solution of ethyl chloride in an equal bulk of alcohol, has been used as an internal stimulant, in the dose of ten to thirty minims (0.6 to 1.8 Ce.).

ALCOHOL. U. S. (Br.)

ALCOHOL

(ăl'cō-hōl)

"A liquid composed of about 92.3 percent., by weight, or about 94.9 percent., by volume, of absolute Ethyl Alcohol [$C_2H_5.OH = 45.70$], and about 7.7 percent., by weight, of water. It should be kept in well-closed vessels, in a cool place, remote from lights or fire." *U. S.* "A liquid containing 90 parts by volume of ethyl hydroxide, C_2H_5OH , and 10 parts by volume of water; obtained by the distillation of fermented saccharine liquids." *Br.*

From the titles and definitions above given, which include all the forms of alcohol recognized by the U. S. and Br. Pharmacopœias, it will be perceived that there are three U. S. official Alcohols, and four strengths of diluted alcohol recognized by the British Pharmacopœia, those being considered the same which have nearly the same specific gravities and are employed for similar purposes.

The extensive use of alcohol in pharmacy renders it desirable not only to group the official kinds together here, but to consider each in detail in the subsequent pages. In the U. S. P. (1890) two new kinds of alcohol were made official, "Alcohol Absolutum" and "Alcohol Deodoratum." The former, which had been made official in the Br. Pharm. (1885) under the title "Alcohol Ethylicum," is in the Br. Pharm. (1898) termed "Alcohol Absolutum," so that the two Pharmacopœias are now in accord in this. The U. S. Pharmacopœia (8th Rev.) dismissed Alcohol Deodoratum (U. S. P. 1890), but raised the standards for Alcohol to correspond with those formerly required for the dismissed deodorized alcohol.

Alcohol, in the chemical sense, is a peculiar liquid generated for the most part in vegetable juices and infusions by a *fermentation*, called the *vinous* or *alcoholic*. The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus, the fermented juice of the grape is called wine; of the apple, cider; and the fermented infusion of malt, beer.

With regard to the nature of the liquids susceptible of the vinous fermentation, however various they may be in other respects, one general character prevails; that, namely, of containing sugar in some form or other. It is found, further, that after they have undergone the vinous fermentation the sugar they contain has either wholly or in part disappeared; and it was long believed that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process, and that these, when taken together, are equal in weight to the sugar lost. It was hence inferred that sugar is the subject matter of the changes occurring during the vinous fermentation, and that it is resolved into alcohol and carbon dioxide. More recently, however, it has been shown by Pasteur that, along with alcohol and carbon dioxide, glycerin and succinic acid are generated in small amount, and that the process is not so simple as at first supposed.

Sugar will not undergo the vinous fermentation by itself, but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature by commencing and maintaining the chemical changes. The precise manner in which the ferment operates has not been positively determined; but the fermentative change seems to be intimately connected with the multiplication of a microscopic plant, *Torula cerevisia*. Pasteur has shown that the yeast plant lives and grows at the expense of the sugar, which is converted partly into the plant's tissue, partly into alcohol and other products. The proper temperature for conducting vinous fermentation ranges from 15.5° C. to 32.2° C. (60° to 90° F.).

Certain vegetable infusions, as those of potatoes and rice, readily undergo vinous fermentation, on account of the ease with which their starch is changed into sugar under the influence of certain ferments. Taking the formula of starch as $(C_6H_{10}O_5)_3$ for illustration, it is first changed under the influence of dilute acids or ferments according to the two reactions:

The two compounds, *dextrin* and *maltose*, then pass gradually into dextrose, according to the reactions:

Neither dextrin nor maltose is directly fermentable. Arnould has succeeded in obtaining alcohol by fermenting sugar (glucose), formed by the action of sulphuric acid on poplar wood sawdust, which yielded from 70 to 80 per cent. of this kind of sugar. Simmson (*Ap. Ztg.*, 1898, 776) obtained 6.5 liters of absolute alcohol from 100 kilogrammes of air dried sawdust. The action of sulphurous acid upon wood fibre has been found by Clâssen to be even more satisfactory as a saccharifying agent, and the process has been successfully used in practice.

Alcohol, being the product of the vinous fermentation, necessarily exists in all vinous liquors, and may be obtained from them by distillation. Formerly it was supposed that these liquors did not contain alcohol, but were merely capable of furnishing it, in consequence of a new arrangement of their ultimate constituents, and the result of the heat applied. Brande, however, disproved this idea, by showing that alcohol may be obtained from all vinous liquors without the application of heat, and therefore must pre-exist in them. His method of separating it consists in precipitating the acid and coloring matter from each vinous liquor by

lead subacetate, and removing the water by potassium carbonate. According to Gay-Lussac, litharge, in fine powder, is the best agent for precipitating the coloring matter.

In vinous liquors, the alcohol is largely diluted with water, and associated with coloring matter, volatile oil, extractive, ethereal substances, and various acids and salts. In purifying it, advantage is taken of its volatility, which enables it to be separated by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The distilled product of vinous liquors forms the different *ardent spirits of commerce*. When obtained from wine, it is called brandy; from fermented molasses, rum; from cider, malted barley, or rye, whisky; from malted barley and rye meal with hops, and rectified from juniper berries, Holland gin; from malted barley, rye, or potatoes, and rectified from turpentine, common gin; and from fermented rice, arrack. These spirits are of different strengths, that is, contain different proportions of alcohol, and have various peculiarities by which they are distinguished by the taste. Their strength is accurately judged by the specific gravity, which is always less in proportion as their concentration is greater. When they have the sp. gr. 0.920 (0.91984, Drinkwater), they are designated in commerce by the term *proof spirit*. The United States Custom House and Internal Revenue Service defines the term *proof spirit* to be alcohol containing 50 per cent. by volume of absolute alcohol at 15.6° C. (60° F.).

Proof spirit is still very far from being pure, being a diluted alcohol, containing about half its weight of water, together with a peculiar oil and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. Whisky is the spirit usually employed for this purpose; and from every hundred gallons, between fifty-seven and fifty-eight may be obtained, of the average strength of rectified spirit (sp. gr. 0.835), corresponding very nearly with the *Spiritus Rectificatus* of the Br. Pharm. When this is once more cautiously distilled, it may be further purified from water, and the specific gravity attained will be about 0.820, which is the lightest spirit that can be obtained by ordinary distillation, and is practically the pure spirit of the British system of excise. It still, however, contains 11 per cent. of water. In the meanwhile, the spirit, by these repeated distillations, becomes more and more freed from the contaminating oil, called *grain oil* or *fusel oil*. (See *Alcohol Amylicum*.) The synthesis of alcohol from ethylene through the intervention of ethyl-sulphuric acid has long been known to be a scientific possibility; with the production of acetylene industrially from calcium carbide, this synthesis has been asserted to be a commercial possibility. Acetylene, made as stated from calcium carbide and water, is generated in the same flask in which nascent hydrogen is being formed, the result being the pro-

duction of ethylene gas. This is brought in contact with concentrated sulphuric acid at 80° C., when the two unite to form ethyl-sulphuric acid, which is then condensed and redistilled, when it breaks up into alcohol and sulphuric acid, which later can be used over again. The reactions for this synthesis are:

Wood (*Chem. News*, 1898, 308), after repeated experiments, doubts the probability of making alcohol synthetically by this process. Berthelot announced the formation of alcohol synthetically, by the union of olefant gas with water, but in this discovery he was anticipated by Hennel, who published it in 1828.

We shall first consider the general properties of alcohol, and afterwards the different official forms.

Properties.—Alcohol, using this term in a generic sense, is a colorless, transparent, volatile liquid, of a penetrating, agreeable odor, and burning taste. It should be free from foreign odor, which, when present, is owing to fusel oil. When free from water, it is called *anhydrous* or *absolute alcohol*. It is inflammable, and burns without smoke or residue, forming water and carbon dioxide. Its flame is bluish when strong, but yellowish when weak. It combines in all proportions with water and ether, and, when diluted with distilled water, preserves its transparency. Its density varies with the proportion of water it contains. (See alcohol tables, PART III.) Its value depends upon the quantity of absolute alcohol contained in it; and, as this is greater in proportion as the specific gravity is less, it is convenient to take the density of a sample as a means of estimating its strength.

This is done by instruments called hydrometers or alcoholmeters, which, when allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Each hydrometer degree has a corresponding specific gravity, and, by referring to tables constructed for the purpose, the percentage of absolute alcohol is at once shown. Hydrometer manufacturers graduate instruments showing specific gravity and Baumé's degrees upon the same scale in parallel columns, with a thermometer taking the place of the bulb; these are exceedingly convenient. Alcoholmeters are also constructed to show the alcohol percentage by weight directly, as well as percentage of proof spirit.

Alcohol is used enormously in the arts as a solvent and for other purposes, and the U. S. government has established suitable regulations permitting the proper use of alcohol in manufacturing and controlling its use as a beverage. The liquid treated so that it is rendered unfit for use in beverages is termed *denatured* or *denaturalized alcohol*. The introduction of *methylated spirit* (alcohol with 10 per cent. of methyl

alcohol) has not proved effective. (See *Methylic Alcohol*, PART II.) The French excise directs that alcohol should be denatured or deprived of its natural properties by the addition of 500 Cc. of petroleum benzin and 1 Gm. of malachite green to each hectoliter; it has been found, however, that the color can be destroyed by calcium hypochlorite.

The dangerous properties of methyl alcohol when taken internally caused the Committee of Revision of the U. S. P. (8th Rev.) to introduce a test which is very reliable for determining the presence or absence of methyl alcohol, which is sometimes used as an adulterant for alcohol. It is as follows: *Methyl Alcohol Test*, U. S. P. (8th Rev.). "Into a test-tube of the capacity of about 40 cubic centimeters, 1 Cc. of the Alcohol or spirit to be tested should be poured, and, if it be undiluted, enough distilled water added to make the liquid measure 10 Cc. If the alcohol be already diluted, a correspondingly larger volume of it should be taken and diluted to 10 Cc., so that the proportion of alcohol in the liquid shall not be more than about 10 percent., by volume. A copper wire spiral (made by winding 1 meter of No. 18 clean copper wire closely around a glass rod 7 millimeters thick, making a coil about 3 centimeters long, the end of the wire being formed into a handle) should be heated to redness in a flame free from soot, and plunged steadily quite to the bottom of the liquid in the test-tube and held there for a second or two, then withdrawn and dipped into water to cool. This treatment with red-hot copper should be repeated five or six times, immersing the test-tube in cold water to keep down the temperature of the liquid. The contents of the test-tube should now be filtered into a wide test-tube and boiled very gently. If the odor of acetaldehyde be perceptible, the boiling is to be continued until the odor ceases to be distinguished clearly. The liquid is now cooled, and to it should be added 1 drop of a solution containing 1 part of resorcinol in 200 parts of water. A portion of this liquid is then poured cautiously into a second tube containing pure sulphuric acid, in such a way that the two liquids shall not mix, the tube being held in an inclined position; this tube is allowed to stand for three minutes, and then slowly rotated. No rose-red ring should show at the line of contact of the two layers (absence of more than 2 percent. of *methyl alcohol*)."
U. S.

Alcohol is capable of dissolving a great number of substances; as, for example, sulphur and phosphorus in small quantity, iodine and ammonia freely, and the hydroxides of potassium, sodium, and lithium, but not the carbonates of these metals. Among organic substances, it is a solvent of most of the vegetable alkaloids, urea, tannic, citric, and tartaric acids, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil, which is abundantly soluble in it. It reacts chemically with some acids, forming the ethyl esters, but with others acts

only as a solvent. All deliquescent salts are soluble in alcohol, except potassium carbonate; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it. It dissolves ammonium chloride, and most of the chlorides readily soluble in water; also some nitrates, but none of the metallic sulphates.

A method of detecting alcohol in small proportions has been proposed by Carstanjin. The liquid supposed to contain it, having been mixed with platinum black in a small flask, is heated to 51.1° C. (124° F.), well shaken, and filtered. To the filtrate a few drops of solution of potassium hydroxide are added, and the liquor evaporated to dryness on a water bath. The residue is then heated with a little arsenic trioxide, when, if alcohol be present, a garlicky odor will be perceived, owing to the production of cacodyl. According to Nickles, however, propylic alcohol will produce the same result. (*A. J. P.*, 1865, p. 334.) A very delicate test for small quantities of alcohol is that of Lieben as modified by Hager. (*Zeit. An. Chem.*, ix. 492.) It depends on the fact that alcohol under the influence of iodine and an alkali yields iodoform, CHI_3 , the properties of which are very characteristic. To 10 Cc. of the clear suspected liquid five or six drops of a 10 per cent. solution of potassium or sodium hydroxide are added, and the liquid is warmed to about 50° C. (122° F.). A solution of potassium iodide fully saturated with free iodine is next added drop by drop, with agitation, until the liquid becomes permanently yellowish brown, when it is carefully decolorized by a further cautious addition of the caustic alkali solution. If alcohol be present, iodoform is gradually deposited at the bottom of the tube in yellow crystals, which, after standing, may be examined with a lens. Spirit diluted with 2000 parts of water, when treated as above and allowed to stand twelve hours, gives a distinct dust-like deposit of iodoform. Unfortunately, the above delicate reaction is not peculiar to alcohol, being produced by acetone, aldehyde, propylic and butylic alcohols, various ethers, etc. On the other hand, it is not given by pure methyl or amyl alcohol, chloroform, chloral, glycerin, or ether, nor by acetic, formic, or oxalic acids. (*Allen, Com. Org. Anal.*, 2d ed., i. p. 59; see also *A. J. P.*, Feb. 1877, Feb. 1879, Nov. 1879; *N. R.*, Aug. 1876.) Barfoed of Copenhagen, recommends for an approximate simple test, to moisten small slips of filtering paper thoroughly with the alcohol, and set fire to them. If, when the alcohol has burned out, the paper slip catches fire readily, the alcohol must be stronger than 80 per cent.; if the paper barely catches fire, the strength may be presumed to be between 75 and 80 per cent.; if it does not catch fire at all, the alcohol cannot be stronger than 73 or 75 per cent. (*A. J. P.*, Jan. 1875.)

Alcohol tables will be found in PART III, which will give the specific gravities of the various strengths of alcoholic liquids. The tem-

perature at which the specific gravities of these liquids is taken was not changed to 25° C. (77° F.) in the U. S. P. (8th Rev.), as it was for most liquids, because the temperature 15.6° C. (60° F.) was the one adopted by the U. S. government and still retained by it, for all of the national legal requirements.

ALCOHOL ABSOLUTUM. *Absolute Alcohol, Anhydrous Alcohol, Ethylic Alcohol.*—No process is given in the U. S. Pharmacopœia for the preparation of absolute alcohol; the definition given, however, is "Ethyl Alcohol [$\text{C}_2\text{H}_5.\text{OH} = 45.70$], containing not more than 1 percent., by weight, of water." *U. S.* The following is the process of the Br. Pharmacopœia (1885): "Rectified Spirit, 1 pint [Imp. meas.]; Carbonate of Potassium, anhydrous, 2 ounces [av.]; Chloride of Calcium, fused, a sufficiency. Add the carbonate of potassium to the spirit in a stoppered bottle, and macerate for twenty-four hours with frequent agitation. Put the chloride of calcium into a covered crucible, and subject it to a red heat for half an hour; then pour the fused salt on to a clean stone slab, cover it quickly with an inverted porcelain dish, and when it has congealed, break it up into small fragments and enclose in a dry stoppered bottle. Put one pound [av.] of this fused chloride of calcium into a flask, pour over it the spirit decanted from the carbonate of potassium, and, closing the mouth of the flask with a cork, shake them together and allow them to stand for twenty-four hours with repeated agitation. Then attaching a dry condenser closely connected with a receiver from which free access of air is excluded, and applying the flame of a lamp to the flask, distil about two fluidounces [Imp. meas.], which should be returned to the flask, after which the distillation is to be continued until fifteen fluidounces [Imp. meas.] have been recovered." *Br.* 1885. By the term absolute alcohol is meant pure alcohol, entirely free from water. In this state it cannot be obtained by ordinary distillation alone, the purest alcohol thus procured still containing 5 per cent. of water. To separate this it is customary to have recourse to substances having a very strong affinity for water, sufficient not only to abstract it from the alcohol, but to retain it at a temperature at which alcohol will distil over. Soubeiran recommends the following method for obtaining it, and the British process is largely based upon this plan. 1st. Rectify alcohol marking 86° of the centesimal alcoholmeter of Gay-Lussac (rectified spirit), by distilling it from potassium carbonate. This operation should raise its strength to 94° or 95°. 2nd. Raise this alcohol to 97° by distilling it with fused calcium chloride, or by digesting it with quicklime (from which it must be afterwards poured off), in the proportion of a pint of the alcohol to 1½ ounces of the chloride, or 2½ ounces of the lime. 3rd. Distil the product of this operation slowly with quicklime, in the proportion of 3¾ ounces to the pint. The product will be absolute alcohol. The operation

may be shortened to two steps by distilling the alcohol of 94° or 95° with an excess of quicklime (7½ ounces to the pint). In all cases, before decanting or distilling, the alcohol must be digested for two or three days with the lime, at a temperature between 95° and 100° F. Lime will not answer as a substance to be distilled from, unless it be in sufficient excess; for otherwise, towards the end of the distillation, the calcium hydroxide formed will yield up its water to the alcohol, and weaken the distilled product. J. Lawrence Smith (*Amer. Chemist*, Oct. 1874) procures an alcohol of 98 to 100 per cent. by macerating 3 pints of alcohol, 94 per cent., in a four-pint bottle with about six troyounces of well burned lime; well corked and agitated at intervals for ten days, the strengthened alcohol, at the end of this time, is drawn off by a siphon, and may be freed, if desired, of the small trace of lime by redistillation. Yvon prepares absolute alcohol by treating strong alcohol with powdered calcium carbide (*Chem. News*, 1898, 52).

Properties.—Absolute alcohol is a colorless, volatile liquid, of an agreeable odor and burning taste. It boils at 78.4° C. (173.1° F.), and is congealed at -130.5° C. Its sp. gr. is 0.7978 at 68°, according to Regnault; 0.79381 at 60°, according to Drinkwater; 0.794 (equivalent to 99.95 per cent. of ethyl hydroxide by volume and by weight) to 0.7969 (equivalent to 99.4 per cent. of ethyl hydroxide by volume or 99 per cent. by weight), by the British Pharmacopœia; while E. R. Squibb has shown that pure alcohol is obtainable of as low a density as 0.7935, and possibly lower. (*Ephem.*, ii. p. 522.) The sp. gr. of its vapor is 1.59. Absolute alcohol is officially described as "a transparent, colorless, mobile, and volatile liquid, of a characteristic, rather agreeable odor, and a burning taste. Very hygroscopic. Specific gravity: not higher than 0.797 at 15.6° C. (60° F.); or 0.790 at 25° C. (77° F.). In other respects Absolute Alcohol has the properties, and should respond to the reactions and tests, of Alcohol (see *Alcohol*)." U. S. "Mixed with 1 to 2 per cent. of anhydrous copper sulphate in a well-closed bottle, and the mixture set aside for two or three hours and occasionally well shaken, the salt does not become of a decidedly blue color (absence of excess of water). Absolute Alcohol should be free from the impurities mentioned under 'Alcohol (90 per cent.)' and in other general characters should resemble it." Br. The tests usually given to prove the absence of water by dropping into the absolute alcohol anhydrous barium oxide or anhydrous copper sulphate are not reliable, as Squibb has demonstrated that when half of one per cent. of water was added to absolute alcohol no change in either the barium oxide or the anhydrous copper sulphate took place. Görgen's test of forming a clear solution when mixed with an equal bulk of pure benzene is more delicate, but a test for determining the presence of as little as one per cent. of water is

needed. Absolute alcohol should be free from fusel oil. Absolute alcohol burns with a pale flame without residue, the products being carbon dioxide and water. Its vapor, passed through a porcelain tube filled with pumice stone and heated to redness, yields carbon, gaseous hydrocarbons, aldehyde, naphthalene, benzene, phenol, and various other substances. (Berthelot.) It unites in all proportions with ether and water. Its union with water is attended by condensation and a rise of temperature. When 52.6 volumes of alcohol are mixed with 47.4 of water, corresponding with one molecule of the former to three of the latter, the decrease of volume is at the maximum, amounting to 3.4 per cent.

Composition.—Absolute alcohol consists of two atoms of carbon, six of hydrogen, and one of oxygen. Its empirical formula is, therefore, C_2H_6O . It is, however, recognized as the hydroxide of the radical ethyl (C_2H_5), so that its rational formula would be $C_2H_5.OH$.

During the vinous fermentation sugar disappears, and the sole products were formerly supposed to be alcohol and carbon dioxide, which, taken together, were believed to equal in weight the lost sugar; the comparative composition of the substances concerned supports the opinion that these are the sole derivatives of a portion of the sugar lost. Preparatory to the fermentation, the cane sugar is changed into *grape sugar*, or into a mixture of equal molecules of *dextrose* and *levulose*, called *invert sugar*, according to the reaction given on page 104. These two sugars, dried at 100° C. (212° F.), consist of $C_6H_{12}O_6$. Supposing one molecule of this fermentable sugar to be the subject of the change, it will be found to have a composition which admits of its being broken up into two molecules of alcohol and two of carbon dioxide:

But it does not follow that all the sugar has been converted into alcohol and carbon dioxide; and Pasteur, as before stated, has shown that a portion lost has not been thus converted, but has been partly appropriated to the growth of the yeast plant of the ferment, and partly changed into glycerin and succinic acid.

ALCOHOL. U. S. *Alcohol*, sp. gr. 0.816 at 15.6° C. (60° F.).—This is the so-called "95 per cent. alcohol" of commerce (or 94.9 per cent. by volume); it was an official preparation of the Dublin College, which gave a formula for its preparation, and stated its sp. gr. at 0.818. The Stronger Alcohol introduced into the U. S. P. (1860), though of the sp. gr. 0.817, and therefore a little stronger than the old Dublin preparation, was for all practical purposes identical with it. The British Pharmacopœia (1898), under the title "*Spiritus Rectificatus*," recognizes alcohol of 90 per cent. by volume. This is slightly stronger (1.35 per cent.) than the alcohol of the same name in the Br. Pharm. (1885). To prepare it on a small scale, potassium carbonate,

previously ignited in a heated mortar, may be mixed with ordinary alcohol in a bottle, and shaken occasionally for about four hours, the mixture being, in the meantime, maintained at the temperature of about 100° F. Upon standing, the liquid divides into two layers, the lower consisting of an aqueous solution of potassium carbonate, the upper of the stronger alcohol, which is to be separated, and distilled so as to obtain the measure of about nine-tenths of the original alcohol employed.

It is described as "a transparent, colorless, mobile and volatile liquid, of a slight, agreeable odor, and a burning taste. Specific gravity: about 0.816 at 15.6° C. (60° F.), the standard temperature for Alcohol, or 0.809 at 25° C. (77° F.). Miscible with water in all proportions, and without any trace of cloudiness; also miscible with ether or chloroform. It is readily volatilized, even at low temperatures, and boils at 78° C. (172.4° F.). It is inflammable, and burns with a pale blue, smokeless flame. It should not affect the color of blue or red litmus paper previously moistened with water. If 50 Cc. of Alcohol be evaporated in a clean glass vessel, no color or weighable residue should remain. If 10 Cc. of Alcohol be mixed with 5 Cc. of water and 1 Cc. of glycerin, and the mixture allowed to evaporate spontaneously from a piece of clean, odorless blotting paper, no foreign odor should become perceptible when the last traces of the Alcohol leave the paper (absence of *fusel oil constituents*). If 25 Cc. be allowed to evaporate spontaneously in a porcelain evaporating dish, carefully protected from dust, until the surface of the dish is barely moist, no red or brown color should be produced upon the addition of a few drops of colorless, concentrated sulphuric acid (absence of *amyl alcohol*, or *non-volatile, carbonizable, organic impurities*, etc.). If 10 Cc. of Alcohol be mixed in a test-tube with 5 Cc. of potassium hydroxide T.S., the liquid should not at once assume a yellow color (absence of *aldehyde* or *oak tannin*). If 20 Cc. of Alcohol be shaken in a clean, glass-stoppered vial with 1 Cc. of silver nitrate T.S., the mixture should not become more than faintly opalescent, or acquire more than a faint brownish tint when exposed for six hours to diffused daylight (limit of *organic impurities, amyl alcohol, aldehyde*, etc.)." *U. S.* "Specific gravity 0.8340. It contains 85.65 per cent. by weight of ethyl hydroxide, C_2H_5OH , and 14.35 per cent. by weight of water. It burns with a blue smokeless flame. It leaves no residue when evaporated (absence of fixed matter). It remains clear when mixed with water (absence of oily or resinous substances). A little exposed on clean white filter paper leaves no unpleasant smell after the alcohol has evaporated (absence of fusel oil and allied impurities). 100 cubic centimetres, with 2 cubic centimetres of the volumetric solution of silver nitrate, exposed for 24 hours to bright light and then decanted from the black powder which has formed, undergo no

further change when again exposed to light with more of the *volumetric solution* (absence of more than traces of amyl alcohol and of other organic impurities). When mixed with half its volume of solution of potassium hydroxide, the liquid should not immediately darken in color (absence of more than traces of aldehyde). The addition of solution of ammonia should not cause an immediate darkening in color (absence of tannic acid, excess of aldehyde, and other organic impurities)." *Br.*

On a large scale, alcohol of this strength is now prepared in the United States, very abundantly, by simple distillation by means of a modified distillatory apparatus known as a "still and column." The modification consists in substituting for a single refrigerated receiver a series of receivers, kept at such temperatures that, in the first of them, the aqueous vapor shall condense with comparatively little of the alcoholic, which, as it passes through the successive recipients, is more and more deprived of water, until, when condensed in the last, it yields a spirit at least as strong as the official Alcohol of the sp. gr. 0.816. At the same time that the spirit is thus strengthened, it becomes, on the same principle, more and more freed from fusel oil, until almost wholly deprived of it.

The British preparation contains 14.35, the U. S. only 7.7 per cent. of water. Official alcohol, though of standard strength, may still be impregnated with a volatile principle, called *fusel oil*. This is usually separated by digesting the alcohol with charcoal. It, as well as other impurities, may also be removed by passing the impure spirit through a filtering bed, composed of sand, wood charcoal, boiled wheat, and broken oyster shells, arranged in layers. If 5 Cc. of alcohol be mixed with 6 times its volume of water and then agitated with about 20 drops of chloroform, the latter will, if separated and allowed to evaporate spontaneously, leave the fusel oil, which will be perceptible by its odor; and by treating with a little sulphuric acid and potassium acetate, its peculiar ether may be recognized by its odor. (*Ber. d. Chem. Ges.*, viii.; *A. J. P.*, 1875, p. 304.) If a little of the solution of silver nitrate be added to alcohol and the mixture exposed to a bright light, a black powder will be precipitated, if fusel oil be present. Official alcohol will not withstand this test, as the best contains a little of the foreign oil. According to E. N. Kent of New York, silver nitrate will not detect fusel oil, but affords its indications by reacting with other organic substances. For detecting fusel oil, Kent finds pure sulphuric acid the best test. To apply it he half fills a test tube with the spirit to be tested, and then fills it up very slowly with pure concentrated sulphuric acid. If the spirit be pure, it will remain colorless, otherwise it will become colored, the tint being deeper in proportion to the amount of the impurity. The presence of a small proportion of fusel oil is readily detected by the use of this test.

Deodorized alcohol is, as its name implies, alcohol deprived of foreign odor; there are certain uses in pharmacy for which any other alcohol would be unsuited, such as the solution of volatile oils and essences having delicate odors, the manufacture of compound spirits, etc. This was official in the U. S. P. 1890, under the title *Alcohol Deodoratum*, but, inasmuch as it is easily obtained in the United States, at a slight advance in price over commercial alcohol, its standards of purity, odor and strength were retained for the *Alcohol* of the U. S. P. (8th Rev.), see page 103, hence the alcohol used in pharmacopœial preparations is now deodorized alcohol.

The best deodorized alcohol is that manufactured under Atwood's patent process, in which manganic acid or potassium or sodium permanganate is used to destroy fusel oil and other foreign substances. This alcohol withstands the tests of silver nitrate and sulphuric acid remarkably well. Pure fused sodium acetate has been proposed as a substance particularly adapted to retain fusel oil, and has been used by adding it to the alcohol to be rectified in the proportion of about 10 pounds to the barrel of forty-five gallons, and redistilling. The purification of alcohol is best accomplished, according to Schmitt, by taking crude alcohol containing 30 per cent. by volume, adding potassium carbonate (not enough to cause two layers to form), and agitating with pure petroleum benzine; this solvent removes completely the fusel oil from the alcohol. After separating the light layer, potassium carbonate is added to the alcohol in sufficient quantity to form two layers, the lower one consisting of a saturated solution of potassium carbonate, the upper one of 94 per cent. alcohol containing a small quantity of potassium carbonate. The alcohol layer is siphoned off and mixed with just sufficient strong sulphuric acid to precipitate the potassium salt as sulphate, which is insoluble in alcohol of 94 per cent., and which can then be removed. Alcohol purified in this manner, without distillation, it is stated, cannot be distinguished from that purified by the usual method. (See *Ph. Central.*, 1889, p. 722.) F. G. Earl recommends the following method, which has the advantage of requiring no special apparatus. "Rub four drachms of powdered unslaked lime with two drachms of powdered alum intimately; add one gallon (95 per cent.) alcohol, and shake well, then add one fluidrachm of spirit of nitrous ether, set aside for seven days, and filter through animal charcoal." (*C. D.*, 1895, 35.) *Perfumers' alcohol* can now be had, which is very much cleaner than *cologne spirit*, as the purest alcohol attainable was formerly called. It is termed *perfumers' alcohol* because it was found necessary to prepare a very high grade of alcohol for those who need a solvent for fine odors, on the score of economy and to insure greater excellence of product.

ALCOHOL DILUTUM. U. S.—"A liquid composed of about 41.5 percent, by weight, or

about 48.9 percent, by volume, of absolute Ethyl Alcohol [$C_2H_5.OH = 45.7$], and about 58.5 percent, by weight, of Water." *U. S.* Specific gravity about 0.936 at 15.6° C. (60° F.) and about 0.930 at 25° C. (77° F.). The strength of diluted alcohol has been somewhat altered by the U. S. P. (8th Rev.) Since the present official alcohol is somewhat stronger than that of the U. S. P. 1890, the strength of diluted alcohol is correspondingly slightly increased.

*Diluted alcohol is officially made by mixing equal measures of alcohol and water together.*¹

* "Alcohol, five hundred cubic centimeters [or 16 fluidounces, 7 fluidrachms, 15 minims]; Distilled Water, five hundred cubic centimeters [or 16 fluidounces, 7 fluidrachms, 15 minims]. Mix them. If the two liquids be measured at the temperature of 25° C. (77° F.), the mixture, when cooled to the same temperature, will measure about 970 Cc. [or 32 fluidounces, 384 minims]. *Diluted Alcohol* may also be prepared as follows: Alcohol, four hundred and eight grammes [or 14 ounces av., 171 grains]; Distilled Water, five hundred grammes [or 17 ounces av., 279 grains]. Mix them." *U. S.*

The British Pharmacopœia (1898) no longer uses the titles "*Spiritus Tenuior*" or "*Proof Spirit*" for diluted alcohol, but admits four official liquids under the name of diluted alcohol, as follows:

"1. **Alcohol (70 per cent.)**.—With one hundred fluid ounces of Alcohol (90 per cent.) mix thirty-one (more accurately 31.05) fluid ounces of Distilled Water. Or, with one thousand cubic centimetres of Alcohol (90 per cent.) mix three hundred and ten and a half (310.5) cubic centimetres of Distilled Water. Specific gravity 0.8900.

2. **Alcohol (60 per cent.)**.—With one hundred fluid ounces of Alcohol (90 per cent.) mix fifty-three and two-thirds (more accurately 53.65) fluid ounces of Distilled Water. Or, with one thousand cubic centimetres of Alcohol (90 per cent.) mix five hundred and thirty-six and a half (536.5) cubic centimetres of Distilled Water. Specific gravity 0.9135.

"**RULES FOR MAKING AN ALCOHOL OF ANY REQUIRED LOWER PERCENTAGE FROM AN ALCOHOL OF ANY GIVEN HIGHER PERCENTAGE:**

I. *By Volume*.—Designate the volume-percentage of the stronger alcohol by V, and that of the weaker alcohol by v.

Rule.—Mix v volumes of the stronger alcohol with distilled water to make V volumes of product. Allow the mixture to stand until full contraction has taken place, and until it has cooled, then make up the deficiency in the V volumes by adding more distilled water.

Example.—An alcohol of 30 percent. by volume is to be made from an alcohol of 94.9 percent. by volume.—Take 30 volumes of the 94.9 percent. alcohol, and add enough distilled water to produce 94.9 volumes.

II. *By Weight*.—Designate the weight-percentage of the stronger alcohol by W, and that of the weaker alcohol by w.

Rule.—Mix w parts by weight of the stronger alcohol with distilled water to make W parts by weight of product.

Example.—An alcohol of 50 percent. by weight is to be made from an alcohol of 92.3 percent. by weight.—Take 50 parts by weight of the 92.3 percent. alcohol, and add enough distilled water to produce 92.3 parts by weight." *U. S.*

3. Alcohol (45 per cent.).—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *one hundred and five and one third* (more accurately 105.34) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *one thousand and fifty-three and a half* (more accurately 1053.4) *cubic centimetres* of Distilled Water. Specific gravity 0.9436.

4. Alcohol (20 per cent.).—With *one hundred fluid ounces* of Alcohol (90 per cent.) mix *three hundred and fifty-five and three-quarters* (more accurately 355.8) *fluid ounces* of Distilled Water. Or, with *one thousand cubic centimetres* of Alcohol (90 per cent.) mix *three thousand five hundred and fifty-eight* (3558.0) *cubic centimetres* of Distilled Water. Specific gravity 0.9760." Br.

This is a convenient pharmaceutical method of providing suitable menstrua for making tinctures, fluidextracts, and other galenical preparations, which have been adopted by the British Pharmacopœia.

"Diluted Alcohol has a specific gravity of about 0.936 at 15.6° C. (60° F.), the standard temperature for Alcohol, and about 0.930 at 25° C. (77° F.). It should respond to the reactions and tests given under *Alcohol*." U. S.

Uses.—The local action of alcohol is that of an active irritant and germicide; in the absence of better antiseptic remedies it may afford a very useful application to wounds and even to infected sores, upon which it should be used freely and of strengths varying from 50 to 80 per cent. When it is taken habitually in excess, its local irritant influence often leads to the production of gastritis, to that form of hepatitis which is known in its advanced stage as cirrhosis of the liver, and to inflammatory disease of the kidney. Very frequently, especially when the alcohol is taken well diluted and with an abundance of food, the organic changes produced by its continued use are rather those of fatty degeneration of the liver and kidneys, and it may be of the heart, than of inflammation. It is absorbed with rapidity, is either completely oxidized in the system or in part eliminated unchanged, according to the amount which has been ingested, the animal organism having apparently the power of burning up only so much alcohol. The excess of alcohol escapes chiefly through the kidneys but probably to a greater or less extent through the lungs and skin. The single large dose of alcohol will produce the condition known as drunkenness, ending, if sufficient of the poison has been taken, in absolute muscular relaxation, profound stupor, fall of bodily temperature, collapse, and it may be, death.

The treatment of alcoholic narcotism consists in immediate washing out of the stomach, in the maintenance of the bodily temperature by external warmth if the fall has been great, and in the hypodermic injection of strychnine, cocaine and atropine to maintain respiration, and of digitalis for its action upon the heart.

Alcohol in small doses acts as a stimulant to the ganglionic cells of the cerebrum, and perhaps also to the motor tract of the spinal cord. In large amount it certainly is a depressant to the cerebral and spinal ganglionic cells, as well as the nerve trunks. The action of small doses upon the respiratory centres is not thoroughly established, but large doses depress the respiratory centres, and finally may cause death by centric paralytic asphyxia. Alcohol does not usually increase the arterial pressure, but when in moderate doses it increases to a remarkable degree the rapidity of the flow of blood through the arteries. It does this by stimulating the heart and by depressing the vasomotor centres, widening out the blood vessel system so that there is increase of the driving force and lessening of the resistance. The toxic dose of alcohol depresses both the heart and the blood vessel system, decreasing the rate of flow through the blood vessels and the arterial pressure. The peripheral temperature is often increased by small amounts of alcohol, and there may be even a slight increase in the central temperature, probably caused by quickening of the circulation; the large dose of alcohol depresses the animal temperature, probably by causing vasomotor paralysis, and thereby increasing heat dissipation.

In regard to the effect of alcohol upon the nutrition there is much contradictory evidence, but the present probabilities are that the drug has no specific influence upon the production of heat or of carbon dioxide, or upon nitrogenous elimination, and that therefore it has little or no direct effect upon the nutrition, unless it be in poisonous doses, when it certainly disturbs all nutritive processes. In its oxidation in the system alcohol undoubtedly yields force, and it would appear to be demonstrated that the animal organism has the power of using this force for the purposes of life. In one sense, therefore, alcohol is a food, and our present knowledge indicates that it is, in a measure but not altogether, capable of replacing in the system such hydrocarbons as starch and fats. On the other hand, alcohol is incapable of yielding material to the system which shall be built up into tissue, and it is therefore incapable of supplying the place of any food except in the degree to which it may be used as a source of force.

In acute diseases associated with *debility*, alcohol is often an invaluable remedy. Of all medicines it is the one most frequently employed as a stimulant. Taken along with food in small quantity, it favors digestion by its local effect upon the stomach, and possibly also by stimulating the nerve and arterial centres. It does not directly elevate temperature, and hence is not contra-indicated by fever; in *typhoid* and other *low fevers* it is of great value. In all conditions of depression the system tolerates much more of it than in health; hence in *snake bite*, *typhoid* and *typhus fever*, *diphtheria*, etc., enormous quantities are often exhibited with

great benefit. So long as it is not perceptible in the breath, and does not cause nervous or circulatory excitement, alcohol in these cases is probably not in excess. In chronic diseases great care is necessary in the exhibition of the remedy, for fear of begetting intemperate habits. This is especially the case in *neuralgia* and other painful affections in which the narcotic influence may be very soothing; under these circumstances there is a constant tendency to an increase of the frequency and size of the dose. Taken habitually in excess, alcohol produces the most deplorable results, and is a very common cause of fatal maladies. Locally, alcohol is sometimes used for the purpose of hardening the skin and as an antiseptic dressing for wounds, the wound being washed out with it until all bleeding has ceased, the edges then united, and the whole surrounded by an alcoholic dressing. Pure alcohol is rarely used internally, but only as spirit, wine, or fermented liquor, described elsewhere.

The purer forms of alcohol, whether strong or diluted, are employed almost exclusively in pharmacy; as in the preparation of medicines, such as ether, into the composition of which they enter; for the preservation of organic substances; in the extraction of the active principles of drugs, as in the tinctures; for dissolving bodies soluble in alcohol much more readily than in water, or insoluble in the latter fluid; and for other pharmaceutical purposes. Diluted alcohol is employed as an addition to some infusions and decoctions, and to some of the distilled waters, in order to preserve them from decomposition; as a menstruum for extracting the virtues of plants, preparatory to the formation of extracts and syrups; and in preparing many of the spirits, and a few of the medicated wines. But it is in forming the tinctures that diluted alcohol is chiefly used. Some of these are made with official alcohol (rectified spirit), but the majority with mixtures of alcohol and water of different percentages. As diluted alcohol contains more than half its weight of water, it is well fitted for acting on organic substances the virtues of which are partly soluble in water and partly in alcohol. The apothecary, however, should never substitute the commercial proof spirit for diluted alcohol, on account of the impurities in the former, even though it may be of the same strength, and when it is recollected how variable the so-called proof spirits are in strength, the objection to their use in pharmacy becomes still stronger.

ALOE. U. S.

ALOE [Aloe *Barbadensis*, Aloe *Socotrina*, Pharm. 1890]

(ăl'ô-ê)

"The inspissated juice of the leaves of *Aloe vera* (Linné) Webb, *Aloe Chinensis* Baker, *Aloe Perryi* Baker, or other species of *Aloe* (Fam. *Liliaceæ*)." U. S.

Acibar, Sp.

ALOE BARBADENSIS. Br.

BARBADOS ALOES [Curaçao Aloes]

(ăl'ô-ê băr-bă-dên'sis)

"The juice that flows from the transversely cut leaves of *Aloe vera*, Linn., *Aloe chinensis* Bak., and probably other species, evaporated to dryness. Imported from the West Indian Islands, and known in commerce as Barbados and Curaçao aloes." Br.

Aloës hépatique des Barbades, Fr.; Barbados Aloe, G.

ALOE PURIFICATA. U. S.

PURIFIED ALOES

(ăl'ô-ê pŭ-rî-fî-că'tă)

Aloës dépuré, Fr.; Gereinigte Aloe, G.

* "Aloes, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, two hundred cubic centimeters [or 6 fluidounces, 366 minims]. Heat the Aloes, by means of a water-bath, until it is completely melted. Then add the Alcohol, and, having stirred the mixture thoroughly, strain it through a No. 60 sieve, which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the mass becomes brittle on cooling. Lastly, break the product, when cold, into pieces of a convenient size, and keep it in well-stoppered bottles." U. S.

"Purified Aloes is in irregular, brittle pieces of a dull-brown or reddish-brown color, and having the peculiar odor of Aloes. It is almost entirely soluble in alcohol." U. S.

Aloes, as found in the market, even of good quality, is so often mixed with various accidental impurities, such as fragments of wood, vegetable remains, pieces of leather, and earthy matter, that it has been thought advisable to have an official process by which it may be freed from these, should its purification be found necessary in any particular instance. The use of alcohol in the formula is simply to render the melted aloes more liquid, and thus facilitate the straining; it is subsequently eliminated by evaporation; but care should be taken not to use too great a heat, or to continue it too long, for fear of impairing the virtues of the drug.

Off. Prep.—(See page 117.)

ALOE SOCOTRINA. Br.

SOCOTRINE ALOES

(ăl'ô-ê sôc-ô-trî'nă)

"The juice that flows from the transversely cut leaves of *Aloe Perryi*, Baker, and probably other species of *Aloe*, evaporated to dryness.

Imported principally by way of Bombay, and known in commerce as Socotrine and Zanzibar aloes." Br.

Aloës socotrin, ou sucotrin, Fr.; Socotora oder Socotrinische Aloe, G.; Musebber, Ar.; Acibar Sucotrin, Sp.

The 1890 edition of the U. S. Pharmacopœia agreed with the British in recognizing as distinct varieties Barbados and Socotrine aloes; very wisely, however, in the eighth revision the general title of Aloe was adopted as representing any varieties of the drug which would conform with the official description and tests.

Most plants belonging to the genus Aloe are capable of yielding a bitter juice from which may be prepared an aloes, and there is little doubt that in many cases a commercial aloes exported from one country is the product of several species.

In former editions of the U. S. Dispensatory, Cape aloes was attributed to the *Aloe spicata*, L., but as was originally pointed out by J. Medley Wood (P. J., Dec., 1890), Cape aloes is in fact chiefly yielded by the much larger plant, *A. ferox*, Miller.

The two plants are quite different in appearance. *A. spicata*, L., Willd., *Sp. Plant.* ii. 185, has a simple stem, three or four feet high, about four inches in diameter, with twelve to twenty leaves laxly disposed in the form of a rosette at the top; the leaves themselves are one to one and a half feet long, one and one-half to two inches in breadth near the base; glaucous green, without prickles except on the margin, which is armed with strong, spreading, deltoid, cuspidate prickles one-eighth to one-sixth of an inch long.

A. ferox, Miller (Gard. Dict., ed. viii., No. 22) has a simple stem ten to fifteen feet long, four to six inches in diameter; furnished at the top with a dense rosette containing thirty to fifty leaves, which are lanceolate, one and one-half to two feet long, very rigid, with copious prickles on back and face, the margin armed with brown-tipped deltoid or cuspidate prickles one-eighth to one-sixth of an inch long.

According to L. Pappe, Cape aloes of poor quality is obtained from *A. africana* and *A. plicatilis*, of Miller; while in Lindley's *Flora Medica*, *A. purpurascens*, Haworth, *A. arborescens*, Mill., *A. Commelyni*, Willd., and *A. multifloris* are all said to contribute to commercial Cape aloes. *Curaçao Aloes* is apparently produced by the following species: *A. vera* (L.), Webb, *A. vulgaris*, Lam., *A. spicata*, L., and *A. socotrina*, Lam., all of which have been introduced into the island (see P. J., Jan., Sept., 1890), although E. R. Holmes believes it to be at least in part the product of *A. chinensis*, Baker.

A. socotrina, Lamarek, *Encycl.* i. 85; De Cand., *Plantes Grasses*, fig. 85. *A. vera*, Miller, *Dict.*, ed. viii., No. 55—The stem of this species is erect, eighteen inches or more in height, woody, and leafless below. At top it is embraced by green, sword-shaped, ascending leaves, some-

what concave on their upper surface, convex beneath, curved inward at the point, with numerous small white serratures at their edges.

This plant was supposed to be a native of Socotra and the source of the Socotrine aloes, but was shown by Bolus to be indigenous to the Cape of Good Hope.

A. vera, L. *A. vulgaris*, Lamarek, *Encycl.*, i. 86. *A. barbadensis*, Miller. *A. indica*, Royle. *A. littoralis*, Koenig.—This species has a very short, woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous green color, somewhat mottled with darker spots, flat on the upper surface, convex beneath, and armed with hard reddish spines, distant from each other, and perpendicular to the margin. *A. vera* is a native of Southeastern Europe, Northern Africa, and Madagascar. It is cultivated in Italy, Sicily, Malta, and especially in the West Indies, where it contributes largely to furnish the Barbados aloes.

A. Perryi, J. G. Baker, *Tr. Linn. Soc.*, xxviii. The true Socotrine aloes plant was first described from specimens sent to Kew Gardens by Wykeham Perry, and was subsequently found by Balfour of Edinburgh, growing abundantly upon the island of Socotra, especially in the limestone tracts, from the sea level to an altitude of 3000 feet; along with it, but much less abundant, was a dwarf species with spotted leaves. It resembles in its general habit the Barbados aloes, but differs in its shorter leaves, and especially in its flowers, which are arranged in looser racemes on longer pedicels and have the tube much longer than the segments.

The proper aloetic juice was formerly thought to exist in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely; but, according to E. Robiquet, who made elaborate researches in relation to this drug, these vessels are air ducts, and the juice flows in the intercellular passages between them. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. After condensation by artificial or natural heat the aloes juice is poured into gourds, more commonly boxes, or into monkey skins [Socotrine aloes], allowed to harden and sent into commerce.

Commercial History and Varieties.—Three chief varieties of aloes have been known in comparatively recent commerce: Barbados or Curaçao, Socotrine, and Cape.

BARBADOS ALOES.—This aloes appears to have been brought to London as early as 1693, and to have reached its greatest commercial abundance in the year 1843, when 4227 gourds of it are said to have been exported from Barbados, a gourd containing from twenty to sixty pounds. At present no appreciable quantity is produced in Barbados, the last sale that we know of having taken place in London in 1902. Nevertheless, Barbados aloes is still sold in the

drug stores, being simply selected specimens that look like the old Barbados aloes, taken from aloes produced in various parts of the world. Most of the Barbados aloes was produced from *A. vera*, although *A. socotrina*, *A. purpurascens*, and *A. arborescens* are said to have been cultivated.

The method of obtaining Barbados aloes seems to have varied at different periods of time, and possibly in different portions of the island. According to various authors the lower ends of the freshly cut leaves were put into wooden V-shaped troughs, and the exuding juice collected and dried in the sun or boiled in copper pans; again, a decoction of the chopped-up leaves was boiled to the proper consistency; in either case, when the liquor had become so thick that it hardened on cooling, it was poured into calabashes or gourds.

Barbados aloes, as formerly supplied, varied in color from very dark blackish-brown through reddish-brown and liver-colored to orange-brown. It yielded a dull olive-yellow powder, of a disagreeable, even nauseous odor, and it is described in the British Pharmacopœia as follows: "Fracture either dull and waxy, in which case small splinters are opaque; or smooth and glassy, in which case the splinters are transparent; the opaque variety examined under the microscope exhibits numerous minute crystals embedded in a transparent mass." *Br.* "Mixed with nitric acid, it acquires a red color. Barbadoes Aloes is not colored, or acquires only a light bluish-green tint, on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*)." *U. S.* 1890.

According to Marais, Barbados aloes could be distinguished by the fact that its solution in distilled water, 1 to 100,000 parts, yielded on the addition of gold chloride or of tincture of iodine a fine rose color, all other varieties of aloes producing with the reagents named either a feeble color of slow development, or no change of color whatever.

CURAÇAO or BONAIRE ALOES.—This aloes, which is produced in the Dutch West Indian Islands, chiefly in the Island of Aruba, appears not to have entered commerce extensively before the early part of the 19th century, but at present constitutes a very large proportion of commercial aloes. It occurs chiefly in three forms; first, an opaque, brittle aloes, showing abundant crystals under the microscope, and sold in gourds usually as Barbados aloes; second, aloes having an appearance like the first variety but sold in cases; third, glossy Curaçao or Capey Curaçao aloes, which occurs in cases and is glossy and transparent.

It is affirmed that the difference in these varieties of Curaçao aloes depends upon the extent of the evaporation by artificial heat, the aloes being dark colored and opaque when poured into the gourds while still soft; glossy and transparent when allowed to evaporate to dryness over the fire. It is said that the juice

is obtained by allowing the leaves to drain into V-shaped troughs, and that it is never evaporated spontaneously.

According to P. van der Wielden, shining Curaçao aloes dissolves completely in nitric acid with the production of a red color, while the dull Curaçao aloes, giving the same color reaction, fails to entirely dissolve. Kremel gives a method to distinguish Curaçao aloes from other kinds by adding to it a little cupric sulphate solution, then some saturated solution of common salt, which makes the color an intense carmine. The reaction is due to *cupro-aloin*. (*C. D.*, 1895, 759.) Curaçao aloes is sometimes found in the markets which has been deprived of its aloin; this fraudulent product is then sold as Cape aloes; the odor of the Curaçao variety still remains.

SOCOTRINE ALOES.—This variety appears to have been the original aloes, having been produced in the island of Socotra at least as early as the time of Alexander the Great, 333 B.C., who is said to have sent a commission to investigate its manufacture. Very little, however, of the true Socotrine aloes at the present time comes into the Western markets, the aloes which reaches European commerce from Bombay, Muscat, Aden, and Zanzibar having various botanical and geographical origins.

It is stated that the production of aloes in Arabia was formerly a government monopoly, but that at present it is entirely free to the inhabitants. The leaves, which are cut at any time of year, are allowed to drain into a goat's or sheep's skin, and the gathered juice permitted to evaporate spontaneously. In the course of about one month, when it has become thick and viscid, it is known by the Arabic name of *Jâyeḡ Gesheeshah*; several weeks subsequently, when it has become hard, it is called *Jâyeḡ Kasahul*. Due to its exposure throughout the long process of desiccation, all the varieties of Socotrine aloes contain much foreign matter, which, according to E. R. Squibb, amounts to from 7 to 22 per cent. of the bulk.

The best Socotrine aloes occurs in pieces varying from a dark ruby-red to a yellowish or reddish-brown, more or less semi-transparent, with a glossy surface and a smooth or ragged but not conchoidal fracture, and yielding a bright golden-yellow powder. Its odor is peculiar, almost fragrant, especially developed by breathing upon the aloes, and its bitter, disagreeable taste has a somewhat aromatic tang. The poorest variety of Socotrine aloes, *Mocha aloes* of the East, is soft, dark, and malodorous. Even the finest Socotrine aloes may consist of an orange or yellow colored distinctly fragrant, semi-liquid mass, while the variety known as *Zanzibar aloes* usually occurs in liver-brown masses, with a dull, waxy fracture, a characteristic odor and a nauseous, bitter taste. The variability of Socotrine aloes probably depends upon not only different methods of preparation but a different origin. "Almost entirely soluble in alcohol and in 4 parts of boiling water.

The aqueous solution becomes turbid on cooling and yields a deposit. . . The powder, on being thoroughly dried on a water-bath and then heated to 100° C., should not cake. Mixed with nitric acid, it acquires a reddish-brown color. Socotrine Aloes is not colored blue on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from *Natal aloes*).” *U. S.* 1890. Both Zanzibar and true Socotrine Aloes “are opaque even in small splinters, exhibit when examined under the microscope numerous minute crystals embedded in a transparent mass, and impart to *nitric acid* a reddish or yellowish-brown color.” *Br.*

The general method of collecting Cape aloes is to allow the excised leaves to drain into a sheep's skin, which has been so placed in a hole in the ground as to force the juice to collect in the centre. Later this juice is evaporated by artificial heat, and when sufficiently concentrated, poured into boxes or skins. Cape aloes differs from Socotrine aloes especially in its brilliant conchoidal fracture and peculiar odor, which is strong, but neither nauseous nor aromatic. When freshly broken it has a very dark olive or greenish color approaching to black, presents a smooth, bright, almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow color, and, being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. Cape aloes, when quite hard, is very brittle and readily powdered; but in very hot weather it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter.

Uganda or *crown aloes* is a brand of Cape aloes produced by manufacturers who buy the aloes juice from the collectors, allow it to undergo a slight fermentation, and dry it in the sun in wooden troughs. It is sent into commerce in bags containing coarse or fine powder, or chips, and in bricks wrapped in red paper; it has a very bitter, aromatic taste and a strongly aromatic odor. The bricks are of a hepatic brown color, with a resinous fracture, which has a bronzy-gold lustre by reflected light. Splinters are translucent, but not garnet-red. With nitric acid it forms a brown solution, gradually changing through dull brownish-yellow to a deep green color.

Natal aloes is a variety coming from Natal, on the southeast coast of Africa, which occurs in irregular pieces, with a fracture much less shining than that of Cape aloes and a totally different color, having a greenish slate hue. It yields a greenish-brown powder, which has the odor of Cape aloes. It is less soluble

than Cape aloes, and has a peculiar composition, which will be adverted to under the chemistry of the drug.

Besides the chief varieties of aloes, others are or have been known in the market. *Hepatic aloes*, as well as *fetid*, *caballine* or *horse aloes*, have no proper claim to be considered distinct varieties, being simply inferior aloes of various origins, the first liver-colored, the second blackish and fetid and full of impurities. *Jafferabad aloes*, supposed to be the same as *Mocha aloes* (*A. J. P.*, 1881, 175), has been shown to be the product of *A. abyssinica*, Lam., and is said by Shenstone to contain *̄*-barbaloin (*A. J. P.*, 1883, 92). Aloes made in India from the *A. vera* is known as *Musambra aloes*. It appears to be a very inferior variety, and rarely, if ever, reaches Europe (*P. J.*, Aug., 1889).

It is evident that the labels under which aloes are largely sold often have little or no connection with the place of production, or with the variety of aloes in the package. This fact has probably come about through the indifference of retail druggists to the variety of the aloes which they are using, an indifference largely due to their common habit of buying aloes in powder. Wilbert (*A. J. P.*, 1903), proposed that aloes should be classified as follows:

Aloes A.—Containing barbaloin; responds to Bornträger's test for emodin, but does not give a distinct red color with nitric acid, or with Klunge's test.

Aloes B.—Containing isobarbaloin with barbaloin; responds to Bornträger's test for emodin, and also gives a deep red color with strong nitric acid, or with Klunge's test.

The revisers of the *U. S. Pharmacopœia* have acted wisely in refusing to recognize all varieties of aloes, requiring only that any specimens shall conform to the following description and tests: “In yellowish-brown or orange-brown to blackish-brown opaque masses; translucent in thin fragments; fracture uneven, dull and waxy, somewhat resinous, or smooth and glassy, somewhat conchoidal; occasionally exhibiting microscopic crystals of aloin; odor characteristic; taste nauseous, bitter. Aloes gives a reddish color with nitric acid or with solutions of the alkalies. If Aloes be dried at 100° C. (212° F.) until it ceases to lose weight, the loss of moisture should not exceed 10 per cent. A solution of Aloes in hot water yields, with a concentrated solution of sodium borate, a mixture having a greenish fluorescence. If to 5 Gm. of Aloes 60 Cc. of boiling water be added, a nearly clear solution should be obtained, from which not more than 2 Gm. should separate on cooling. If to 1 Gm. of Aloes 5 Cc. of Alcohol be added, and the mixture gently heated, a nearly clear solution should be obtained after cooling the liquid (absence of *gum*, *dextrin*, and *inorganic impurities*).” *U. S.*

Chemical Properties.—Several distinguished chemists have investigated the nature and com-

position of aloes. Braconnot found a bitter principle, which he named *resino-amer* (*resinous bitter*), and another substance in smaller proportion, which he designated by the name of *flea-colored principle*. These results were essentially confirmed by Trommsdorff, Bouillon-Lagrange, and Vogel. Robiquet obtained a product from aloes which he called *aloëtin*. (For details, reader is referred to 14th ed. U. S. Dispensatory.)

ALOINS.—The bitter substances noticed above, viz., the *resino-amer* of Braconnot, and the *aloëtin* of Robiquet, probably contain the active principle of aloes, but combined with impurities which render it insusceptible of crystallization. It has been assumed that there exists not one compound, but a set of three closely related compounds, to which the general name of *aloins* is now given. The first of these, found exclusively in Barbados aloes, and discovered by T. and H. Smith, is called *barbaloin*; the second, discovered by Flückiger in Natal aloes, is called *nataloin*; the third, found by Histed and Flückiger in Socotrine aloes, is called *socaloin*.

Hugo Bornträger asserts that one part of aloes in 5000 can be detected in the following manner. A little of the suspected liquid is shaken with about twice its bulk of benzin, which is allowed to separate, decanted, and shaken with a few drops of stronger water of ammonia. On separation the ammonia will be of a clear red color. With solids a tincture should first be made. According to R. H. Groves (*P. J.*, 3d ser., xi. 1045), this test will never succeed with a less concentration than 1 part in 250, and with some aloes 1 in 100, and is due to the tannin-like substance of aloes; he also states that extreme care is necessary to have the benzin solution perfectly clear. (*P.*

J., 1885, p. 633. For Hager's quantitative method for determining the percentage of aloin in aloes, see *A. J. P.*, 1885, p. 237.)

R. A. Cripps and T. S. Dymond have given the testing of aloes a lengthy investigation, and they recommend the following method. Place 1 grain of the substance in a glass mortar standing on white paper, now add 16 drops of strong sulphuric acid and triturate until dissolved, then add 4 drops of nitric acid, sp. gr. 1.42, and then 1 ounce of distilled water. If aloes be present, a color varying from deep orange to crimson will be produced, according to the kind of aloes that has been used; the color is deepened by the addition of ammonia. The table below is taken from the paper of Bainbridge & Morrow (*P. J.*, Jan. 1890). Under the heading of Kew Specimens are given the results obtained with juice of aloes plants grown in Kew Gardens.

The three aloins, *barbaloin*, *nataloin*, and *socaloin*, are easily distinguished by the following reaction, first noticed by Histed. A drop of nitric acid on a porcelain slab gives, with a few particles of barbaloin or nataloin, a vivid crimson (rapidly fading in the case of barbaloin, but permanent with nataloin unless heat be applied), but produces little effect with socaloin. To distinguish barbaloin from nataloin, test each by adding a minute quantity to a drop or two of sulphuric acid, then allowing the vapor from a rod touched with nitric acid to pass over the surface. Barbaloin (and socaloin) will undergo no change, but nataloin will assume a fine blue. (*Pharmacographia*, 2d ed., p. 688.) E. von Sommaruga and Egger consider that the three aloins form a homologous series possessing the formulas: barbaloin, $C_{17}H_{20}O_7$; nataloin, $C_{18}H_{18}O_7$; socaloin, $C_{15}H_{16}O_7$, and that they are all derived from anthra-

cene, $C_{14}H_{10}$. Tilden subsequently assigned a different composition to the aloins: barbaloin and socaloin, each $C_{16}H_{12}O_7$; for nataloin, the formula $C_{23}H_{22}O_{11}$. He further states that barbaloin and socaloin differ in physical and chemical properties on account of the variation in the molecules of water which are associated with them. Léger assigns to nataloin the formula $C_{23}H_{22}O_{10}$. The British Pharmacopœia (1898) assigns to barbaloin the formula $C_{16}H_{12}O_7 \cdot 3H_2O$. Two bases only are recognized now, *barbaloin* (or simply *aloin*) and *isobarbaloin*. According to Léger (*P. J.*, 1902, 21) *Cape aloes* contains from 5 to 6 per cent. of *aloin* (*barbaloin*) without any admixture of the isomeric *isobarbaloin*. The Barbados aloes of English commerce never gave more than 5 per cent. of *barbaloin* with but minute traces of *isobarbaloin*, which, however, is always met with in the so-called Barbados aloes of French commerce. *Curaçao aloes* is rich in *aloin*, containing 10 per cent., of which half is *barbaloin* and the other half *isobarbaloin*. *Jafferabad aloes* is very rich in *aloin*, yielding 20 per cent., chiefly in the form of *isobarbaloin*. *Socotrine aloes* does not contain more than 4 per cent. of *aloin*, almost wholly *barbaloin* with a very little *isobarbaloin*. Since *barbaloin* is found in almost all varieties, the significance of the prefix "barb" is misleading. The only aloes in which it does not occur is that of Natal.

Tschirch of Berne, Switzerland, published in the *Journal of the German Pharmaceutical Society* (viii., 1898, Heft 6) an important communication, in which he showed that *emodin*, $C_{15}H_{10}O_5$, or *trioxymethylanthraquinone*, is the purgative principle of the aloins. He succeeded in obtaining *emodin* in orange-red crystals which melt at $216^\circ C$. *Emodin* was found in the aloins obtained from Cape, Barbados, and Socotrine Aloes; it is extracted by treating *barbaloin* with ether, which dissolves out the *emodin*. Tschirch found that if a liquid extract of aloes be deprived of its resin and *aloin*, an additional quantity of *emodin* could be obtained by boiling the liquid extract with diluted sulphuric acid, thus pointing to the fact that *emodin* may be produced through hydrolysis. He also showed that *emodin* could be obtained from purgative drugs of the same class as aloes: *rhubarb*, *rumex*, *frangula*, *cascara*, *senna*, *rhamnus catharticus*, *morinda bark*, and *parmelia*. (See *Emodin*, PART II.)

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the inert portion, or apotheme of Berzelius, is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by oxidizing the *aloin* and rendering it insoluble. The alkalies, their carbonates, and soap alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odor of the drug.

Those substances only are incompatible with aloes which alter or precipitate the soluble matter, as the insoluble portion is without action upon the system. Among these is the infusion of galls, which we have found, probably through its tannic acid, to afford a copious precipitate with an aqueous solution of aloes. It is said that such a mixture will keep a long time, even for a period of several months, without mouldiness or putrescence, though it becomes ropy.

Uses.—Aloes was known to the ancients. It is mentioned in the works of Dioscorides and Celsus, the former of whom speaks of two kinds. The varieties are similar in their mode of action. They are all cathartic, operating very slowly but certainly, and having a peculiar affinity for the large intestine, and especially its pelvic portion. Their action, moreover, appears to be directed rather to the muscular coat than to the exhalant vessels, and the discharges which they produce are, therefore, seldom very thin or aqueous. In a full dose they quicken the circulation, and produce general warmth. When frequently repeated, they are apt to irritate the rectum. Aloes has a decided tendency to the uterine system. Its emmenagogue effect, which is often very considerable, is generally attributed to a sympathetic extension of irritation from the rectum to the uterus, but we can see no reason why the medicine should not act specifically upon this organ, and its influence in promoting menstruation is by no means confined to cases in which its action upon the neighboring intestines is most conspicuous. A peculiarity in the action of this cathartic is, that an increase of the quantity administered, beyond the medium dose, is not attended by a corresponding increase of effect. Its tendency to irritate the rectum may be obviated, in some measure, by combining with it soap or an alkaline carbonate; but it does not follow, as supposed by some, that this modification of its operation is the result of increased solubility, for aloes given in a liquid state produces the same effect as when taken in pill or powder, except that it acts somewhat more speedily. Besides, when externally applied to a blistered surface, it operates exactly in the same manner as when internally administered, thus proving that its peculiarities are not dependent upon the particular form in which it may be given, but on specific tendencies to particular parts. (Gerhard, *N. Am. Med. and Surg. Journ.*, x. 155.) With its other powers, aloes combines the property of slightly stimulating the stomach. It is, therefore, in minute doses, an excellent remedy in habitual *costiveness* attended with torpor of the digestive organs. It has been supposed to stimulate the hepatic secretion, and certainly acts sometimes very happily in *jaundice*, producing bilious stools even after calomel has failed. From its special direction to the rectum, it has been found peculiarly useful in the treatment of *ascarides*, and is prescribed for *hemorrhoids* without inflammation. In *amenorrhæa* it is perhaps more frequently employed

than any other remedy, entering into almost all the numerous empirical preparations habitually resorted to by women in that complaint. It is much used in regular practice, and is frequently combined with more irritating cathartics, in order to regulate their liability to excessive action. In *amenorrhœa* it is said to be peculiarly efficacious when given, in the form of enema, about the period when the menses should appear. Aloes is unsuitable, unless modified by combination, to the treatment of inflammatory diseases.

Dose (medium), ten grains (0.65 Gm.), but as a laxative it will often operate in the quantity of two to three grains (0.13 to 0.20 Gm.), and when a decided impression is required, the dose may be augmented to twenty grains (1.3 Gm.). In consequence of its excessively bitter and somewhat nauseous taste, it is most conveniently administered in pills.

ALOINUM. U. S., Br.

ALOIN

(āl-ō'īnūm)

"A neutral principle obtained from Aloes, varying more or less in chemical composition and physical properties according to the source from which it is obtained. Chiefly prepared from Curaçao Aloes." *U. S.* "Aloin is extracted from Barbados or Socotrine Aloes by solvents and purified by recrystallization. The products from the different varieties of Aloes possess similar properties. The Aloin extracted from Barbados Aloes has the formula $C_{15}H_{15}O_7, 3H_2O$." *Br.*

Although aloin has been used for many years, it was not recognized by the U. S. Pharm. until the revision of 1890.

Preparation.—Aloin may be prepared by W. A. Tilden's process as follows: 1 part of aloes is dissolved in 10 parts of boiling water acidulated with hydrochloric acid, and allowed to cool. The liquid is then decanted from resinous matter, evaporated to about 2 parts, and set aside two weeks for crystals to form; the liquid portion is poured off, the crystals pressed, and the adherent resinous matter separated by shaking with acetic ether, which dissolves the resin. This process answers fairly well for

obtaining aloin from Barbados or Curaçao aloes. Aloin from Socotrine aloes is best obtained by digesting the aloes in 3 parts of alcohol for 24 hours, then transferring to a water bath, and boiling for 2 hours. After cooling, the liquid is filtered and set aside to crystallize. The crystals are washed with a little alcohol and dried. The yield is about 10 per cent. (H. C. Plenge, *A. J. P.*, 1894, p. 507.) Schäfer obtains from 15 to 30 per cent. of crystallized aloin from commercial aloes by the following process: 50 Gm. of aloes dissolved in 300 Cc. of hot water are slightly acidulated with hydrochloric acid. The solution, after standing (for the resins to separate), is decanted, mixed with 50 Cc. of 20 per cent. ammonia water, followed by a solution of 15 Gm. of calcium chloride in 30 Cc. of water. The liquid is agitated and the aloin-calcium compound which separates is collected, drained, and mixed in a mortar with a slight excess of hydrochloric acid; the mixture of aloin and calcium chloride is dissolved in the smallest possible quantity of boiling water, filtered, and the filtrate cooled by means of ice; the aloin crystallizes. (*P. J.*, 1897, p. 237.) The yield of aloin from Curaçao aloes varies from 5 to 30 per cent.

Aloin is officially described as in "a micro-crystalline powder or minute acicular crystals, lemon-yellow to dark yellow in color, possessing a slight odor of aloes and an intensely bitter taste. It is slightly hygroscopic, the air-dried powder yielding 1 molecule of water of crystallization at 100° C. (212° F.). Aloin from Curaçao Aloes is soluble in about 65 parts of water, 10.75 parts of alcohol, 664 parts of ether, 4260 parts of chloroform, 3120 parts of benzene, 1475 parts of petroleum benzin, and 21 parts of acetone, at 25° C. (77° F.). The melting point of Aloin from Curaçao Aloes which has been dried over sulphuric acid, is about 147° C. (296.6° F.). When ignited, it is consumed without leaving a residue. Aloin dissolves in water, forming a yellow solution, which is neutral to litmus paper, turns brown on standing, and has an intensely bitter taste. Ammonia water and alkali-solutions dissolve Aloin, forming a yellow solution, soon turning red and exhibiting a greenish-red fluorescence. Nitric Acid dissolves Aloin from Curaçao Aloes, forming a cherry-red solution (distinction from *Nataloin*, *Socaloin*, and *Capaloin*). Aloin when added to alkaline solutions is rapidly decomposed, but if mixed with acid solutions decomposition is slower. Aloin added in minute quantity to concentrated sulphuric acid forms a yellowish-red solution which, upon the addition of a small crystal of potassium dichromate, changes to an olive-green, then to a dark green, and finally, on standing, to a blue. If a large amount of potassium dichromate be used, the yellowish-red solution first turns purple, then brown, and finally green. Bromine water added to the aqueous solution of Aloin produces a pink color. Gold chloride T.S., when added to an aqueous solution of Aloin, turns it carmine-

red, changing later to violet. A drop of ferric chloride T. S. added to an alcoholic solution of Aloin produces a brownish-green color. If to a dilute aqueous solution of Aloin obtained from Curaçao Aloes, 1 drop of copper sulphate T. S. be added, a bright yellow color will be produced; upon adding a few drops of a concentrated solution of sodium chloride, the liquid will acquire a red color, and upon the further addition of a little alcohol the color will be changed to violet (distinction from *Nataloin* and *Capaloin*). On shaking 1 Gm. of Aloin with 10 Cc. of benzene for one minute and filtering, the filtrate should not impart more than a faint pink color to an equal volume of ammonia water (5 percent.), when shaken with it (limit of *emodin*).” U. S. Aloin of commerce is frequently contaminated with resin from aloes, indicating want of care in manufacturing. According to Serre (*D. C.*, 1895, 8), this may be detected by finely powdering 1 grain of the sample, shaking it in a test tube with 20 Cc. of water, and allowing it to stand one minute. The solution should be perfectly clear. See also paper by C. H. LaWall (*Proc. Penn. Pharm. Assoc.*, 1895, 92).

Uses.—Socaloin and barbaloin are active purgatives in doses of 2 to 4 grains. Barbaloin is affirmed to be the more powerful, and, according to the researches of Hans Moyer (*A. E. P. P.*, xxviii.), when given hypodermically in the dose of four-fifths of a grain (0.05 Gm.), it produces repeated moderate purging in from seven to twenty-two hours. Moyer found that Nataloin, though acting energetically upon dogs, usually fails to affect the alvine discharges in man, except when the person has for some days been fed exclusively upon animal food. In combination with belladonna and strychnine, as in the official compound laxative pill, aloin is one of the most serviceable and pleasantly acting laxatives that we have. Frommüller (*L. M. R.*, 1879, p. 70) affirms that aloin dissolved in 25 times its weight of water acts as an efficient though slow purgative, when given hypodermically, without causing any local irritation; Moyer found that formamide is an apt vehicle for the hypodermic use of barbaloin; in making it, the solution may be warmed, but not heated, for fear of producing ammonia.

Dose, as a laxative, one-fourth grain (0.016 Gm.); as a purgative, one grain (0.065 Gm.).

ALTHÆA. U. S.

ALTHÆA [Marshmallow]

(äl-thæ'a)

“The dried root of *Althæa officinalis* Linné (Fam. *Malvaceæ*), collected from plants of the second year's growth, and deprived of the periderm.” U. S.

Radix Hibisci, *Radix Bismalvæ*; Wymote, White Mallow, Mortification root; Racine de Guimbaue, Guimbaue, Fr.; *Radix Althææ*, P. G.; *Altheewurzel*, Althee, Elbischwurzel; Elbisch, G.; *Altea*, Malva-vischio, It.; *Altea*, Raiz de Malva-visco, Sp.

Althæa officinalis, Willd., *Sp. Plant.* iii. 770; Woodv., *Med. Bot.* p. 552, t. 198.—*Althæa* is an herbaceous perennial, with a perpendicular branching root and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are alternate, petiolate, nearly cordate on the lower part of the stem, oblong-ovate and obscurely three-lobed above, somewhat angular, irregularly serrate, pointed, and covered on both sides with a soft down. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obovate petals, of a pale purplish color. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country on the borders of salt marshes. In some parts of the continent of Europe it is largely cultivated for medicinal use, particularly in Germany, where, in the neighborhood of Nuremberg and Schweinfurt, about 15 tons are harvested annually. The whole plant abounds in mucilage. The flowers, leaves, and root are mucilaginous, and were formerly official; but only the last is employed to any considerable extent in this country.

The roots should be collected in autumn from plants at least two years old. They are usually prepared for the market by removing the epidermis; commerce is supplied from Europe.

Properties.—*Althæa* occurs “slenderly tapering, 15 to 30 Cm. long, rarely exceeding 20 Mm. in diameter; externally whitish, traversed longitudinally by several broad, shallow furrows, and covered with loosened bast fibres; fracture of bark fibrous, of wood short and granular; internally yellowish-white; odor faint; taste sweetish, mucilaginous. The powder contains rosette-shaped crystals of calcium oxalate, about 0.025 Mm. in diameter, and ellipsoidal starch grains from 0.010 to 0.020 Mm. in diameter.” U. S. Sections of the root assume a bright yellow tint when an alkali is added to them. The plump and but slightly fibrous pieces of the root are to be preferred. The woody part, on examination with the microscope, is seen to consist of scalariform or pitted vessels, and a few ligneous cells embedded in a loose parenchymatous tissue. The bark is composed of numerous branched liber cells, in bundles of 3 to 30 fibres separated by parenchymatous tissue. The abundant mucilage is situated chiefly in the parenchymatous cells, and can be seen to be in layers when alcohol is added. It, with starch and saccharine matter, is taken out by boiling water. The mucilage, without the starch, is extracted by cold water, which thus becomes ropy. Marshmallow is said to become somewhat acid by decoction. Pieces should be rejected which are woody, discolored, mouldy, of a sour or musty smell, or of a sourish taste. A principle was discovered in the root by Bacon, which has been ascertained to be identical with

asparagin, $C_4H_8N_2O_3 + H_2O$. Boutron-Charland and Pelouze found it to belong to that class of organic principles which are convertible by strong acids, and other agencies, into ammonia and organic acids, and which are designated by the termination *amide*, being compounds of acid radicals with the group NH_2 derived from ammonia by the withdrawal of an atom of hydrogen. When such an amide is acted upon by acids, it is decomposed, the acid radical taking OH to form the free acid and the amide group taking H to form ammonia. Thus *asparagin*, which in this view should be called *asparamide*, is converted into ammonia and *aspartic acid*, $C_4H_7NO_4$, and one molecule of the resulting ammonium aspartate corresponds with one molecule of *asparamide* and one of water. (*J. P. C.*, xix, 208.) *Asparagin*, being now recognized as a derivative of succinic acid, is called *amido-succinamide*, and the *aspartic acid* is called *amido-succinic acid*. It is found in various other plants besides the marshmallow, as in the shoots of *asparagus*, in *vetches* grown in the dark, in all the varieties of the potato, and in the roots of the comfrey and licorice plant. According to Pira, *asparagin* has acid properties. It has no therapeutic value. *Betaine* (trimethyl-glycocol) has been obtained from *althæa* by Orlov. (*Ph. Z. R.*, 1898.)

The roots of other *Malvaceæ* are sometimes substituted for that of marshmallow, without disadvantage, as they possess similar properties. Among these are *Althæa rosea*, Cav., or *holly-hock*, and *Malva Alcea*, L. The dark purple flowers of a variety of *A. rosea* have been proposed as a test for acids and alkalis. A strong infusion of these flowers imparts to slips of white filtering paper a permanent purplish-blue color, which is reddened by acids, and rendered bluish green by alkalis.

Uses.—The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. A syrup of *althæa* is official in the German Pharmacopœia, and was introduced into the U. S. Pharmacopœias of 1880 and 1890, see U. S. D. 18th edition, p. 1327. Owing to its tendency to ferment rapidly it was not retained in the U. S. P. (8th Rev.). The roots themselves, as well as the leaves and flowers, boiled and bruised, are sometimes employed as a poultice. In France the powdered root is much used in the preparation of pills and electuaries. It enters, as an ingredient, into one mass and two pills of the U. S. P.

ALUMEN. U. S., Br.

ALUM (Potassium Alum, Aluminum and Potassium Sulphate)

(a-lū'men)

"It should contain not less than 99.5 percent. of pure Aluminum and Potassium Sulphate."

U. S. "Aluminium and potassium sulphate (Potassium Alum), $Al_2(SO_4)_3 \cdot K_2SO_4 \cdot 24H_2O$, or aluminium and ammonium sulphate (Ammonium Alum), $Al_2(SO_4)_3 \cdot (NH_4)_2SO_4 \cdot 24H_2O$, produced by the combination of aluminium sulphate with potassium sulphate or with ammonium sulphate." Br.

Alumini et Potassii Sulphas, U. S. 1870. Potassa Alum; Sulphas Aluminico-potassicus; Alum de potasse, Fr. Cod.; Alum, Sulfate d'Alumine et de Potasse, Fr.; Alumen, P. G.; Alaun, Kallialaun, G.; Solfato di alluminio e di potassio, Allume, It.; Sulfato aluminico-potassico, Alumbre, Sp.
Alumini et Ammonii Sulphas, Sulphas Aluminico-Ammonicus; Alum ammoniacal, Fr.; Ammoniak-Alaun, G.

The name alum has been applied indifferently to two salts, one consisting of aluminum tri-sulphate combined with ammonium sulphate, the other of the same salt of aluminum combined with potassium sulphate, and distinguished as *ammonium alum* and *potassium alum*. The former was official in the U. S. P. 1870, but has been replaced by *potassium alum*. *Ammonium alum* is still retained with potassium alum under the title *Alumen* in the British Pharmacopœia.

ALUM (*Aluminum and Potassium Sulphate*. U. S. 8th Rev.).—Potassium alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, from the fact of their containing most or all of its constituents, are called *alum ores*. The principal alum ores are the *alum stone*, which is a native mixture of aluminum sulphate and potassium sulphate, found in large quantities at Tolfa and Piombino in Italy; certain natural mixtures of iron disulphide with alumina, silica, and bituminous matter, called *aluminous schist* or *alum slate*; *bauxite*, a native aluminum hydroxide, and *cryolite*. (See *Sodii Carbonas*.)

At the Solfatara, and other places in Southern Italy, alum was formerly extracted from earths containing it ready formed. The ground being of volcanic origin, and having a temperature of about 104° F. an efflorescence of pure alum formed upon its surface. This was collected and lixiviated, and the solution crystallized by slow evaporation in leaden vessels sunk in the ground. The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months, the mineral being frequently sprinkled with water, in order that it may be brought to a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum united with a certain quantity of aluminum hydroxide. The latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this kind of ore.

Alum slate, when compact, is first exposed to the air for a month. It is then stratified with wood, which is set on fire. The combus-

tion which ensues is slow and protracted. The sulphur is in part converted into sulphuric acid, which unites with the alumina; and the aluminum sulphate thus formed generates a portion of alum with the potassium hydroxide derived from the ashes of the wood. The iron, in the mean time, is almost wholly converted into sesquioxide, and thus becomes insoluble. The matter is lixiviated, and the solution crystallized into alum by evaporation. The mother waters, containing aluminum sulphate, are then drawn off, and made to yield a further portion of alum by the addition of potassium sulphate or potassium chloride, the latter being obtained from the soap boilers, or from native potassium chloride of the Stassfurt deposits. When alum slate is easily disintegrated, it is not calcined, but merely placed in heaps and occasionally sprinkled with water. The iron disulphide gradually absorbs oxygen, and passes into ferrous sulphate, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina, so that, after the chemical changes are completed, the heap contains both ferrous sulphate and aluminum sulphate. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates produced is concentrated to the proper degree in leaden boilers. The ferrous sulphate crystallizes, while the aluminum sulphate, being of a more soluble nature, remains in the mother waters.

These are drawn off, and treated with potassium sulphate in powder, heat being at the same time applied. The whole is then allowed to cool, that the alum may crystallize. The crystals are then separated from the solution, and purified by a second solution and crystallization. They are next treated with water just sufficient to dissolve them at the boiling temperature, and the saturated solution is run into casks or tubs so constructed as to be easily taken to pieces and set up again. In the course of ten or fifteen days the alum concretes into a crystalline mass, from which the mother liquor is let off. The vessel is then taken to pieces, and the salt, having been broken up, is packed in barrels for sale. This process for forming the alum in large masses is called *rocking*.

Alum is largely manufactured by the direct combination of its constituents. With this view, clays are selected as free from iron and calcium carbonate as possible, and calcined to sesquioxide the iron and render them more easily pulverizable; after which they are dissolved, by the assistance of heat, in weak sulphuric acid. Advantage has been found in mixing the clay, previous to calcination, with powdered charcoal, coke, or other carbonaceous matter, in the proportion of about one to six of the clay, and then applying heat by a reverberatory furnace until all the carbon is consumed. It is asserted that the alumina is thus rendered more soluble in the acid. (*P. J.*, Dec. 1857, p. 328.) The aluminum sulphate, thus generated, is next crystallized into alum

by the addition of potassium sulphate in the usual manner. Alum is made in this way from the ashes of the Boghead cannel coal, which occurs near Edinburgh. These ashes, which form the residue of the combustion of the coke derived from the coal used for making gas, contain a considerable quantity of alumina in a state readily soluble in acids. For an account of the manufacture of alum in India, see *C. D.*, 1892, 636. *Bauxite*, a hydrated oxide of aluminum, containing from 56 to 60 per cent. of aluminum oxide, has within recent years become one of the most important raw materials for the alum manufacture. It is found in very rich deposits in Georgia and Alabama. *Cryolite*, a double fluoride of sodium and aluminum, also serves as a source of supply, the aluminum hydroxide being produced as an intermediate product.

The elements *rubidium* and *cæsium* are found in *lepidolite*, and, as much of the alum in continental Europe is made from this mineral, Salzer found samples of commercial potassium alum which contained a considerable quantity of rubidium alum; this contaminated potassium alum is less soluble in water than ordinary alum. (*A. Pharm.*, 1887, p. 217.)

The production of crystallized alum in the United States has decreased in recent years, while that of aluminum sulphate (so-called concentrated alum), containing half the usual quantity of water of crystallization, has steadily increased. In 1902 the production of alum was 8,539 tons, valued at \$299,500, and in 1903, 7,574 tons, valued at \$210,910.

ALUMEN, *Br.* ALUMINII ET AMMONII SULPHAS. *Aluminium and Ammonium Sulphate, Ammonia alum.*—Besides the potassium alum, which is now the only U. S. official variety of this salt, there are several others, in which the potassium is replaced by some other base, as, for example, ammonium or sodium. Of these, *ammonium alum*, or aluminum and ammonium sulphate, was introduced in the U. S. Pharmacopœia at the revision of 1860; and in the Pharmacopœia of 1870 and *Br. Pharmacopœia* it was adopted under the name of alumen. It is made by adding ammonium sulphate to the solution of aluminum sulphate. This kind of alum came into very general use, owing to the comparative cheapness of ammonia, obtained in the process for potassium ferrocyanide, or derived from the liquor of gas works. Ammonium alum was extensively manufactured by Powers & Weightman of Philadelphia. *Scotch alum*, made near Paisley, generally contains both potassium and ammonium. Ammonium alum resembles potassium alum so exactly that it cannot be distinguished by simple inspection; and in composition it is perfectly analogous to the potassium salt. It may be distinguished by subjecting it to a strong calcining heat, after which alumina will be the sole residue; or by rubbing it with potassium hydroxide or lime and a little water, when the odor of ammonia will be perceived.

Properties.—Alum, as usually seen, is officially described as in “large, colorless, octahedral crystals, sometimes modified by cubes, or in crystalline fragments; without odor, but having a sweetish and strongly astringent taste. Soluble in 9 parts of water at 25° C. (77° F.), and in 0.3 part of boiling water; it is also freely soluble in warm glycerin, but insoluble in alcohol. When gradually heated, it loses water; at 92° C. (197.6° F.) it fuses, and if the heat be gradually increased to 200° C. (392° F.), it loses all of its water of crystallization (45.55 percent. of its weight), leaving a voluminous, white residue (see *Alumen Exsiccatum*). An aqueous solution of Alum has an acid reaction upon blue litmus paper. An aqueous solution of the salt affords, with ammonia water, a white, gelatinous precipitate, which is almost insoluble in an excess of ammonia; with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid. When a saturated solution of Alum is shaken with sodium bitartrate T.S., it produces, within half an hour, a white, crystalline precipitate. The aqueous solution of Alum affords, with potassium hydroxide T.S., a white, gelatinous precipitate, which is completely soluble in an excess of the alkali, and this alkaline solution should not evolve the odor of ammonia, even when heated (distinction from, and absence of, *ammonium alum*). The aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). (The subsequent addition of ammonia water, as directed in this test, should be omitted.) The addition of 5 drops of potassium ferrocyanide T.S. to 20 Cc. of an aqueous solution of alum (1 in 20) should not at once produce a blue coloration (limit of iron).” *U. S.* “It is soluble in ten times its weight of cold and in one third of its weight of boiling water, the solution having an acid reaction. It is freely soluble in *glycerin*, insoluble in *alcohol* (90 per cent.). It affords the reactions characteristic of aluminium, of potassium or ammonium, and of sulphates. It should yield no characteristic reaction with the tests for copper, lead, zinc, calcium, or sodium, and only the slightest reactions with the tests for iron.” *Br.* Its sp. gr. is 1.71. It reddens litmus, but changes the blue tinctures of the petals of plants to green. When heated a little above 100° C. (212° F.), it undergoes the aqueous fusion; and, if the heat be continued, it loses its water, swells up, becomes a white, opaque, porous mass, and is converted into the official *exsiccated alum*. (See *Alumen Exsiccatum*.) Exposed to a red heat, it gives off oxygen, together with sulphurous and sulphuric oxides, and the residue consists of aluminum oxide and potassium sulphate. When calcined with finely divided charcoal, it forms a spontaneously inflammable substance, called *Homburg's pyrophorus*, which consists of a mixture of potassium sulphide, alumina, and charcoal. Several varieties of alum are known in commerce. *Roche alum*, so called from its hav-

ing come originally from Rocca, in Syria, is a sort which occurs in fragments about the size of an almond, and of a pale rose color, which is given to it, according to Pereira, by bole or rose-pink. *Roman alum*, which is the purest variety found in commerce, also occurs in small fragments, covered with a reddish-brown powder, resembling ochre, which is put on by the manufacturers. It has been supposed that the powder contains iron, but this is probably a mistake. Roman alum crystallizes in cubes, from the fact that the crystals are deposited from a solution always containing an excess of alumina, which decomposes any iron salt that may be present. This crystalline form of alum is, therefore, an index of its freedom from much contamination with iron.

All the alums of commerce contain more or less ferrous sulphate, varying from five to seven parts in the thousand. The iron is readily detected by adding to a solution of the suspected alum a few drops of potassium ferrocyanide, which will cause a greenish-blue tint, if iron be present. It may be detected also by precipitating the alumina as a subsulphate with a solution of potassium hydroxide, and afterwards adding the alkali in excess. This will redissolve the precipitate, with the exception of any iron, which will be left in the state of sesquioxide. The proportion of iron usually present, though small, is injurious when the salt is used in dyeing. Alum may, however, be purified, either by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools, or by repeated solutions and crystallizations.

Incompatibles.—Alum is incompatible with the alkalies and their carbonates, lime and lime water, magnesium oxide and carbonate, potassium tartrate, and lead acetate.

Composition.—Alum was regarded as an aluminum sulphate, until it was proved by Descroizilles, Vauquelin, and Chaptal to contain also potassium sulphate, ammonium sulphate, or both these salts. When its second base is potassium, it consists of one molecule of aluminum sulphate 339.85, one of potassium sulphate 173.07, and twenty-four of water 429.12 = 942.04, but one half of this molecule of alum is now more often written, making its molecular weight 471.02 for the formula $\text{AlK}(\text{SO}_4)_2 + 12\text{H}_2\text{O}$. In the ammonium alum, the molecule of potassium sulphate is replaced by one of ammonium sulphate. *Alumina* is classed as an earth, and may be obtained by subjecting ammonium alum to a strong calcining heat. It consists of two atoms of the metal *aluminum* 53.8, and three of oxygen 47.64 = 101.44. It is, therefore, a sesquioxide. The existence of this metal was rendered probable by Sir H. Davy in 1808; but it was not fairly obtained until 1828, when Wöhler procured it in an impure state, in globules of the size of a pin's head, by the action of potassium on aluminum chloride. In 1854, Deville succeeded in obtaining the pure metal in ingots by decomposing the same chloride with

sodium. The process of Deville remained the only practical process for its manufacture until 1886, when the Messrs. Cowles of Cleveland, Ohio, succeeded in effecting the reduction of corundum, the native oxide, by charcoal with the aid of a powerful electric current from a Brush dynamo-electric machine, using large carbon electrodes. They manufactured the pure aluminum and the alloys of copper known as aluminum bronzes. This process in turn has been practically displaced by the Hall process, as operated by the Pittsburg Reduction Company at Niagara Falls and elsewhere. This is to electrolyze pure alumina dissolved in a bath of melted cryolite. The cryolite (a double fluoride of sodium and aluminum) is continuously regenerated, so that by feeding in the pure alumina the process can be made continuous. A German process, that of Graetzel, for electrolyzing the fused chloride, is also in successful use.

Aluminum is silver-white, sonorous, unalterable in the air, and lighter than glass, having only the sp. gr. 2.56. Its fusing point is somewhat lower than that of silver. It is not attacked by sulphuric or nitric acid, nor tarnished by hydrogen sulphide. Its proper solvent is hydrochloric acid. After silver, gold, and platinum, it is the least alterable of the metals.

The world's production of aluminum in 1903 was 8,252 metric tons, of which the United States produced 3,402 tons, which was valued at \$2,325,000.

Uses.—Alum is a powerful astringent, with very decided irritant qualities, owing to which, when taken internally in sufficient quantity, it is emetic and purgative, and may even cause fatal gastro-intestinal inflammation. It may be employed in passive relaxations of the mucous membrane or skin, *hemorrhages*, *serous diarrhæa*, *colliquative sweats*, etc., but is not much used internally, except in *colica pictonum*. The latter employment of it was introduced by Grashuis, a Dutch physician, in 1752, was imitated by Percival with great success, and has been revived in recent times with the happiest results. It allays nausea and vomiting, relieves flatulence, mitigates the pain, and opens the bowels with more certainty than any other medicine. Sometimes it is advantageously conjoined with opium and camphor. It is also efficacious in *nervous colic*. Sir James Murray found it a useful remedy in *gastrorrhæa*. He gave it in doses of ten or twelve grains (0.65 to 0.78 Gm.) three or four times a day, mixed with an equal quantity of cream of tartar to prevent constipation, and a little ginger to obviate flatulence. By C. D. Meigs alum has been strongly recommended, in doses of a teaspoonful (3.9 Gm.), in *pseudo-membranous croup* as a mechanical emetic, but its action is not as certain or powerful as is that of zinc sulphate.

Alum is a powerful astringent when topically applied, and has been largely used as such.

In various *anginas* it has been a favorite remedy, but on account of its destructive influence upon the teeth it should never be used alone in gargles, but be applied in powder or concentrated solution with the brush. Bretonneau, Vulpian, etc., strongly recommended it in *pseudo-membranous angina*, applied by insufflation in the case of children. When used in the latter way, a drachm of finely powdered alum may be placed in one end of a tube, and then blown by means of the breath into the throat of the child. Alum coagulates blood very rapidly and firmly, and is frequently used as a local styptic in external *hemorrhages* and in *epistaxis* and other bleedings from the mucous membrane to which it can be applied directly. In *hæmoptysis* its saturated solution may be used by atomization. It is sometimes applied locally in the form of *cataplasms*, made by coagulating the whites of two eggs with a drachm of alum. In *colica pictonum* from 20 to 30 grains of alum in molasses (or thick syrup) may be given three or four times a day. The emetic dose is one to two teaspoonfuls, repeated, if necessary, in fifteen minutes. An elegant mode of giving alum in solution is in the form of *alum whey*, made by boiling two drachms of alum with a pint of milk, and then straining to separate the curd; the dose is a wineglassful (60 Cc.). As a collyrium, a solution is made of various strengths, as 4, 6, or 8 grains to the fluidounce of water. A solution containing from half an ounce to an ounce in a pint of water, and sweetened with honey, is a convenient gargle. In the treatment of *gleet*, *leucorrhæa*, *ulcers*, etc., solutions of alum must vary in strength according to the state of the parts to which they are applied.

In a case recorded by Ricquet of Liège, death resulted from about an ounce of alum taken in solution by mistake for Epsom salt. A sensation of burning in the mouth, throat, and stomach occurred immediately upon the swallowing of the poison, followed by bloody vomiting, and death in the midst of inexpressible suffering. Upon post mortem examination there was found a grayish-yellow coating covering the mucous membrane of the mouth, pharynx, and œsophagus; the tongue and uvula were swollen, and the stomach, bowels, and kidneys were injected. (*J. P. C.*, Oct. 1873, p. 333.)

Alum is sometimes used to adulterate bread, with the view to increase its whiteness and to conceal the defects of the flour. If the quantity used be sufficient, the alum acts as an irritant to the gastro-intestinal tract, and, according to the results of experiments made by Bigelow and Hamilton, it actively checks peptic digestion.

Dose, as an astringent, five to twenty grains (0.32 to 1.3 Gm.); as an emetic, one drachm (3.9 Gm.).

ALUMEN EXSICCATUM. U. S., Br.

EXSICCATED ALUM [Alumen Ustum, Dried Alum, Burnt (Burned) Alum]

(q-lū'mēn ɛx-sic-că'tūm)

AlK(SO₄)₂ = 256.46

"Exsiccated Alum should contain not less than 99 percent. of pure anhydrous Aluminum and Potassium Sulphate." U. S.

Alun calciné, desséché, brûlé, *Fr.*; Alumen ustum, *P. G.*; Gebrannter Alaun, Gebrannter Kallialaun, *G.*; Solfato di alluminio e di potassio usto, Alumne usto, *It.*; Solfato aluminico-potassico anhidro, Alumbre calcinado, *Sp.*

* "Alum, in small pieces, *one hundred grammes* [or 3 ounces av., 231 grains], to make *fifty-five grammes* [or 1 ounce av., 411 grains]. Place the Alum in a tared shallow porcelain dish so as to form a thin layer, and heat it on a sand-bath until it liquefies. Then continue the application of a moderate heat, with constant stirring, until aqueous vapor ceases to be disengaged, and a dry, white, porous mass weighing *fifty-five grammes* [or 1 ounce av., 411 grains] is obtained. When cold, reduce the product to a fine powder, and preserve it in well-stoppered bottles." U. S.

"Potassium Alum, 4 ounces (Imperial) or 100 grammes. Heat the Potassium Alum in a porcelain dish or other suitable vessel till it liquefies, then increase and continue the application of heat until aqueous vapor ceases to be disengaged, and the salt has lost between 45 and 46 per cent. of its weight." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet if the heat be too great the salt itself is decomposed, and the desired end is not attained. If the alum employed be the potassium alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonium salt, which is official in the *Br. P.* To guard against failure from this cause, the Pharmacopœias formerly directed 205° C. (400° F.) as the highest heat to be used, and the checking of the operation when nearly all the water has been driven off, as indicated by the weight of the residue. John M. Maisch satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough, and the direction of the Pharmacopœias, as to the weight of the residue, insures that a sufficient heat will be employed. By the official process there is left behind about one and one-fourth per cent. of the water of crystallization, when potassium alum is used.

Properties.—Exsiccated alum is officially described as "a white, granular powder, without odor, possessing a sweetish, astringent taste, and attracting moisture on exposure to the air.

It is very slowly but completely soluble in about 17 parts of water at 25° C. (77° F.), and quickly soluble in 1.4 parts of boiling water. Its aqueous solution should respond to the reactions and tests given under *Alumen*." U. S. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses 45 per cent. of its weight in dissipated water. Exsiccated alum resists the action of cold water for a long time, showing its altered aggregation. In composition it differs from crystallized alum merely in the absence of water.

Uses.—Exsiccated alum has the same medicinal properties as ordinary alum, except that it is much more powerful and irritant. It is used as a mild escharotic to destroy *exuberant granulations*, on which it should be freely dusted.

ALUMINI HYDROXIDUM. U. S.

ALUMINUM HYDROXIDE [Alumini Hydras, Pharm. 1890]

(q-lū'mī-nī hŷ-drōx'ī-dūm)

Al(HO₃) = 77.54

Aluminum Hydrate, Hydrated Alumina; Argilla Pura, *s.* Hydrata; Hydrate de l'Alumine, *Fr.*; Thonerdehydrat, *G.*

* "Alum, *one hundred grammes* [or 3 ounces av., 231 grains]; Monohydrated Sodium Carbonate, *forty-three grammes* [or 1 ounce av., 226 grains]; Water, a *sufficient quantity*.

Dissolve each salt separately in *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, filter the solutions and heat them to boiling. Then having poured the hot solution of Monohydrated Sodium Carbonate into a capacious vessel, gradually pour in the hot solution of Alum with constant stirring, and add *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of boiling Water. Allow the precipitate to subside, decant the clear liquid, and pour upon the precipitate *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of hot Water. Again decant, transfer the precipitate to a strainer, and wash it with hot Water, until the washings produce not more than a faint cloudiness with barium chloride T.S. Then allow it to drain, dry it at a temperature not exceeding 40° C. (104° F.), and reduce it to a uniformly fine powder." U. S.

Properties.—It is "a white, light, amorphous powder, odorless and tasteless, and permanent in dry air. Insoluble in water or alcohol, but completely soluble in hydrochloric or sulphuric acid, and also in potassium hydroxide T.S. When heated to redness, it loses about 34 per cent. of its weight." U. S.

Tests.—"A solution of 1 Gm. of Aluminum Hydroxide in 20 Cc. of diluted hydrochloric acid should not at once assume a blue color on the addition of 1 drop of potassium ferrocyanide T.S. (limit of iron), and should not give more than a faint cloudiness with barium

chloride T.S. (limit of *sulphate*). If 1 Gm. of the salt be boiled with 20 Cc. of distilled water, and the liquid filtered, the filtrate should not have an alkaline reaction, and on evaporation should leave a residue weighing not more than 0.005 Gm. (limit of *alkali salts*). A solution of the salt (1 in 20) in diluted hydrochloric acid should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). (The subsequent addition of ammonia water, as directed in this test, should be omitted)." *U. S.*

Uses.—A very feebly astringent and desiccant powder, sometimes used externally as an application in inflammatory affections of the skin. So far as our experience goes, it is very rarely employed in this country.

ALUMINI SULPHAS. U. S.

ALUMINUM SULPHATE

(a-lŭ'mj-ni sŭl'phās)

"It should contain not less than 99.5 percent. of pure Aluminum Sulphate." *U. S.*

Sulfate d'Alumine, *Fr.*; Aluminium sulfuricum, *P. G.*; Aluminium sulfat, Schwefelsaure Thonerde, *G.*

A process was given in the U. S. P. 1870 for the preparation of this salt, but the 1880 Committee of Revision very properly omitted the process, merely giving a description and tests for the salt. The process of 1870 is as follows: "Take of Alum, Carbonate of Sodium, each, *four troyounces*; Sulphuric Acid *a troyounce and one hundred and fifty grains*; Water *a sufficient quantity*. Dissolve the salts separately, each in six fluidounces of boiling water, and pour the solution of the Alum gradually into that of the Carbonate of Sodium, then digest with a gentle heat until the evolution of carbonic acid ceases. Collect upon a filter the precipitate formed, and wash it with water, until the washings are no longer affected by chloride of barium. Next, with the aid of heat, dissolve the precipitate in the Sulphuric Acid, previously diluted with half a pint of Water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water-bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stoppered bottle." *U. S.* 1870.

The sodium of the carbonate unites with the sulphuric acid of the aluminum sulphate, with the escape of the carbon dioxide, and the precipitation of the aluminum in the form of an hydroxide, while the undecomposed ammonium sulphate of the alum, and the newly formed sodium sulphate, remain in solution. The aluminum hydroxide is then washed in order to separate any portion of the sulphates adhering to it, the absence of which is shown by the non-action of barium chloride on the washings. It now remains to unite the aluminum hydroxide and

sulphuric acid, which is affected by heating them with water; the salt, which is formed in solution, is obtained by evaporating the solution to dryness. It may also be obtained from the solution by the addition of alcohol, which precipitates it. In the process the several substances are used in very nearly saturating proportions. (See paper on Aluminum Sulphate by J. U. Lloyd, *N. R.*, Aug. 1879, p. 237.)

Aluminum sulphate may be prepared also by the process of Huria and Brunel, which consists in exposing, in an iron cylinder, aluminum and ammonium sulphate (ammonium alum), first dried to separate its water of crystallization, to a cherry-red heat. Aluminum sulphate remains in the cylinder, and the volatilized products are collected in water. The chief of these is ammonium sulphite, which serves for the preparation of a fresh portion of alum, after having been changed into the sulphate by oxidation in the air. It is now also obtained in enormous quantities, for use in the place of alum as a mordant in dyeing, as one of the by-products in the manufacture of soda from cryolite. Aluminum sulphate is also obtained from bauxite.

The American production, chiefly from bauxite, in 1901 amounted to 74,721 short tons; in 1902 to 80,075 tons; and in 1903 to 80,726 tons.

Sometimes free sulphuric acid exists in aluminum sulphate. It may be recognized by the salt imparting a strongly acid reaction to alcohol, also by the fact that the dark violet color imparted to decoction of logwood by aluminum sulphate changes to brown in the presence of free acid. (*A. J. P.*, Nov. 1873.) Wittstein treats the finely powdered salt with absolute alcohol; if the latter does not become acid, no free acid is present. (See also *Proc. A. Ph. A.*, 1887, p. 216.) Egger recommends Pettenkofer's bile reaction for the detection of free sulphuric acid in aluminum sulphate and alum. (*Chem. News*, 1889, p. 169.)

Properties.—As procured by the process of 1870, aluminum sulphate is in the form of a white powder. It may, however, be obtained in lamellar crystals. It is described in the U. S. P. (8th Rev.) as "a white, crystalline powder, or shining plates, or crystalline fragments; without odor, having a sweetish and afterwards an astringent taste, and permanent in the air." *U. S.* As seen in commerce, it is usually in flattened crystalline cakes, which appear as though formed by the cooling of soft masses of minute crystals. It has a sour as well as sweet and very astringent taste, is soluble in its weight of water, and has an acid reaction.

The salt is "soluble in 1 part of water at 25° C. (77° F.), more soluble in boiling water, but insoluble in alcohol. When gradually heated to about 200° C. (392° F.), it loses its water of crystallization (45.7 percent. of its weight). The aqueous solution of the salt has an acid reaction upon blue litmus paper. The

aqueous solution of the salt yields, with barium chloride T.S., a white precipitate insoluble in hydrochloric acid; and with potassium hydroxide T.S., a white, gelatinous precipitate which is soluble in an excess of the alkali, but which is again separated on the addition of a sufficient amount of ammonium chloride T.S." *U. S.*

It is formed by the union of one molecule of alumina, which is an aluminum sesquioxide, and three molecules of sulphuric acid, $\text{Al}_2(\text{SO}_4)_3$, and, when crystallized, contains sixteen molecules of water. The salt is, therefore, an aluminum trisulphate.

Tests.—"If 1 Gm. of Aluminum Sulphate be gently heated with 5 Cc. of potassium hydroxide T.S., the liquid should not evolve the odor of ammonia. A filtered, aqueous solution of the salt (1 in 10) should not become more than faintly opalescent within five minutes after the addition of an equal volume of tenth-normal sodium thiosulphate V.S. (limit of *free acid*). The aqueous solution of the salt (1 in 10) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). (The subsequent addition of ammonia water, as directed in this test, should be omitted). The addition of 5 drops of potassium ferrocyanide T.S. to 20 Cc. of the aqueous solution of the salt (1 in 20) should not produce at once a blue coloration (limit of *iron*)."*U. S.*

Uses.—The soluble simple salts of aluminum have the property of opposing animal putrefaction, but the sulphate is probably the most powerful and certainly is the most used. It has been employed in aqueous solution (20 grains in a fluidounce up to saturation *pro re nata*) as an antiseptic, detergent application to *foul ulcers*, and as an injection in *fetid discharges from the vagina*. Solution of aluminum sulphate is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by Mentel as a hæmostatic, under the name of *benzoinated solution of alumina*. It resembles the *styptic liquid of Pagliari*. It is prepared by saturating with gelatinous alumina a solution made of eight ounces of aluminum sulphate dissolved in a pint of water. To the saturated solution six drachms of bruised amygdaloid benzoin are added, and the whole is kept at a temperature of about 150° F. for six hours, with occasional agitation, so that the liquid, after filtration, may have about the density 1.26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzoinated solution, remarkable for its very sweet odor and astringent balsamic taste. Benzoinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in *leucorrhœa*. Aluminum sulphate in saturated solution has been used for the preservation of cadavers for dissection, but is much inferior to zinc chloride.

AMMONIA.

AMMONIA

(am-mō'nī-ā)

$\text{NH}_3 = 16.93$

All the ammoniacal compounds owe their distinctive properties to their combination with a peculiar gaseous substance, composed of nitrogen and hydrogen, called *ammonia*. This is most easily obtained by the action of lime on ammonium chloride, or sal ammoniac,—when the lime unites with the hydrochloric acid, so as to form calcium chloride and water, and expels the ammonia. It is transparent and colorless, like common air, but possesses an acrid taste and an exceedingly pungent odor. It has a powerful alkaline reaction, and, from this property and its gaseous nature, was called the *volatile alkali* by the earlier chemists. Its sp. gr. is 0.59. It is irrespirable, the glottis closing spasmodically when the attempt is made to breathe it. Each molecule consists of one atom of nitrogen and three of hydrogen, or, in volumes, of one volume of nitrogen and three volumes of hydrogen, condensed into two. Its formula is NH_3 . The sources of ammonia will be mentioned elsewhere (see *Ammonii Chloridum*, p. 131), but a synthesis of ammonia from simple elements may be noted here. Hydrogen, nitrogen, and aqueous vapor in the presence of porous contact substances like pumice, charcoal, etc., unite to form ammonia, and this, in the presence of CO and CO_2 , gives rise to ammonium formate or carbonate.

As the gas ammonia exists in the free state, the molecule NH_3 is a definite saturated compound under ordinary conditions. When, however, ammonia gas is mixed with hydrochloric acid gas or its aqueous solution with hydrochloric acid in solution, the two unite to form a new compound, NH_4Cl , which proves to be a definite compound, analogous to potassium or sodium chlorides. Berzelius, therefore, proposed to call this ammonium chloride, assuming that the monad group (NH_4) acted like the monad metal K in forming compounds, and in fact it is found that when sulphuric, nitric, carbonic, and other acids are neutralized by ammonia gas or solution, crystallizable salts like $(\text{NH}_4)_2\text{SO}_4$, NH_4NO_3 , and $(\text{NH}_4)_2\text{CO}_3$ are formed, which are termed ammonium sulphate, nitrate, and carbonate respectively. Ammonium is believed to exist although it has not been isolated in a pure state. Ammonium amalgam is a compound of ammonium with mercury.

The atmosphere contains a minute proportion of ammonia, probably in the state of carbonate. (A. Vogel, *N. R. Pharm.*, 1872.)

Ozonized oxygen oxidizes the elements of ammonia, producing water and nitric acid; the latter, uniting with undecomposed ammonia, generates ammonium nitrate. Ordinary oxygen, under the influence of platinum-black, or finely-divided copper, likewise oxidizes the ele-

ments of ammonia, the nitrogen to the extent only of forming nitrous acid, with the result of producing ammoniacal nitrite.

AMMONIACUM. Br.

AMMONIAC

(äm-mō-ni'q-cūm)

"A gum-resin exuded from the flowering and fruiting stem of *Dorema Ammoniacum*, *D. Don*; and probably other species." *Br.*

Gummi-resina Ammoniacum or Dorema, Ammoniacum; Ammoniaque, Gomme-résine ammoniaque, Gomme ammoniaque, *Fr.*; Ammoniacum, *P. G.*; Ammoniak, Ammoniak-gummi, *G.*; Gomma ammoniaco, *It.*; Gomo-resina amoniaco, Goma amoniaco, *Sp.*; Ushek, *Ar.*; Semugh belsheren, *Pers.*

This gum-resin was dropped in the Eighth Revision of the U. S. Pharmacopœia on account of its having fallen, at least in America, almost into desuetude.

Formerly ammoniac was believed to be yielded by *Heracleum gummiferum*, Willd.; this plant was, however, ascertained by Sprengel to be a native of the Pyrenees, and not to yield gum at all. A substance resembling true gum ammoniac has long been produced in Morocco, and has been shown by Jackson and by Falconer to be the product of the *Ferula tingitana*, L. This gum is probably the ammoniac of the ancients, which was obtained from Africa; the present official drug comes exclusively from Persia, and is the product of the plant first found by Fontanier in the province of Fars, subsequently described by Mérat and De Lens under the name of *Ferula ammonifera*. David Don (see *Linn. Trans.*, vol. 16), determined that this plant belonged to a new genus, *Dorema*, so that the official authorities now recognize the drug as the product of the *Dorema Ammoniacum*, Don, syn. *Diserneston gummiferum*, Jaubert and Spack (see *Illustrations of Oriental Plants*, Paris 1842). *Dorema Aucheri*, Boiss., and *D. robustum*, Loftus, of Western Persia, are believed to contribute to the official drug.

The ammoniac plant grows spontaneously in Farsistan, Irak, Khorassan, and other Persian provinces. Grant found it abundantly in Syghan near Bamian, on the northwest slope of the Hindu-Kush Mountains. It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers, it appears that in the month of May the plant is pierced in innumerable places by an insect of the beetle kind. The juice, exuding through the punctures, concretes upon the stem, and when quite dry is collected by the natives. Fontanier states that the juice exudes spontaneously, and that the harvest is about the middle of June. According to Grant, the drug is collected in Syghan, like asafetida, from the root of the plant. The gum-resin is sent to Bushire, whence it is transmitted to India,

chiefly to Bombay. A small portion is said to be taken to the ports of the Levant, and thence distributed. The name of the drug is thought to have been derived from the temple of Jupiter Ammon in the Libyan desert, where the ammoniac of the ancients is said to have been collected; but Don considers it a corruption of *Armeniacum*, originating in the circumstance that the gum-resin was formerly imported into Europe through Armenia. The *African Ammoniac*, which is said to have appeared in the London market only in the years 1857 and 1871, has been described by Daniel Hanbury as follows. It is "in large, compact, dark, heavy masses, formed of agglutinated tears of a gum-resin of hard, waxy consistence. The tears are opaque, white or of a pale greenish yellow, mixed with others of a blackish brown, which, with vegetable and earthy impurities, constitute a large portion of the mass." The odor of the drug is feeble, and quite different from that of the Persian gum-resin; its taste slightly acid and very persistent. (*P. J.*, March, 1873, p. 741.) Examined by John Moss, it was found to consist of 67.76 per cent. of resin, 9.1 of gum, 4.29 of water and volatile oil, and 18.85 of bassorin and insoluble matters. (*Ibid.*, p. 742.) It is used chiefly for incense in Mohammedan countries, and is sent eastward by the caravans, or in vessels from the ports of Morocco to Alexandria.

Properties.—Ammoniac comes either in the state of tears, or in aggregated masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out and kept for use. These are of an irregular shape, usually more or less globular, from two to eight lines in diameter, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal, shining, waxy fracture. The masses are often of a darker color and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty-gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand or earth. According to the 1890 U. S. Pharmacopœia, only such masses should be considered up to the standard as are composed entirely of tears "without any intervening dark-colored substance."

The odor of ammoniac is peculiar, and stronger in the mass than in the tears. The taste is slightly sweetish, bitter, and somewhat acid. The sp. gr. is 1.207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odor. It is partly soluble in water, alcohol, ether, vinegar and alkaline solutions. Triturated with water it forms an opaque milky emulsion, which becomes clear upon standing. The alcoholic solution is transparent, but is rendered milky by

the addition of water. "The freshly fractured surface is colored yellow by solution of potassium hydroxide, and dark red or orange by solution of chlorinated soda. If a small fragment be strongly heated in a dry test-tube, the contents of the tube, after cooling, yield with boiling water a solution which when largely diluted with water, and made alkaline with solution of ammonia, does not exhibit a blue fluorescence (distinction from asafetida and galbanum)." *Br.* Martius found 0.4 per cent. of ethereal oil, Flückiger 0.33 per cent. (*Pflanzenstoffe*, 2d ed., p. 962.) Plugge's analysis gives 1.27 per cent. of volatile oil, 5.10 per cent. of water, 2 per cent. of ash, 65.53 per cent. of resin, and 26.10 per cent. of gum. Hager succeeded in procuring the volatile oil in a separate state by repeated distillation with water. It has a penetrating disagreeable odor, and a taste at first mild, but afterwards bitter and nauseous. Flückiger says that the oil contains no sulphur. The resin in ammoniacum usually amounts to about 70 per cent. Unlike the gum-resin of allied plants ammoniacum yields no umbelliferone. When melted with potassium hydroxide it affords protocatechuic acid and resorcinol. The resin of ammoniac is dissolved by alcohol, and by the fixed and volatile oils; but it is divided by ether into two resins, of which one is soluble and the other insoluble in ether. Plugge states that sodium hypobromite, made by dissolving 30 grammes of pure sodium hydroxide in water, adding 20 grammes of bromine, cooling the mixture, and adding distilled water until the whole measures 1 liter, is a sensitive reagent for ammoniac resin. (*A. Pharm.*, 1883.)

Tschirch and Luz have made an elaborate research of the chemistry of ammoniac, and state the following conclusions. Ammoniac contains resin, gum, and volatile oil, together with about 3.5 per cent. of a residue insoluble in water and alcohol. The portion soluble in alcohol and ether is a mixture of a so-called acid resin and a neutral resin, and amounts to 69 per cent. Both resins are free from sulphur, despite the statement of Preiszewski, who considered the latter of them to contain sulphur. The saponification of the so-called acid resin yielded salicylic acid of the formulas $C_6H_4OHCOOH$ and $C_6H_4OHCOOH + \frac{1}{2}H_2O$. Along with this were volatile acids, consisting of valeric and butyric acids, and an alcohol which belongs to the class of resinotannols, and has the same formula as galbalesinotannol, $C_{15}H_{30}O_8$. The resin is, therefore, a salicylic ester of resinotannol. From this resinotannol both the acetyl and the benzoyl derivatives were made, and the formula $C_{15}H_{30}O_8$ thus established. On oxidizing the resinotannol with nitric acid, styphnic acid was obtained, and on fusing it with potassium hydroxide, resorcinol. Volatile oil was found in small amount only. It contains no umbelliferone, and is free from sulphur. The crude ammoniac showed traces of a free acid which was recognized as salicylic both by its fusing point

and the ferric chloride reaction. The gum contained 3.5 per cent. of ash, of which 1.2 per cent. was calcium oxide, so that the gum is probably related to gum arabic, and is an acid calcium arabinat. (*A. Pharm.*, 1895, p. 571.) Dietrich proposes the following tests: 1. Loss at $100^\circ C.$ ($212^\circ F.$). 2. Per cent. of ash. 3. Determination and weighing of alcohol-soluble constituents. 4. Determination and weighing of alcohol-insoluble constituents. 5. Saponification number. 6. Acid number. 7. Ester number. (*Ph. Ztg.*, 96, 401, and *P. J.*, 1900, 647.)

Uses.—This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates, but is now seldom administered. The complaints in which it was most frequently used were *chronic catarrh*, *asthma*, and other *pectoral affections* attended with deficient expectoration without acute inflammation, or with a too copious secretion from the bronchial mucous membrane, dependent upon debility of the vessels. It is usually administered in combination with other expectorants, with tonics, or with emmenagogues. Externally applied, in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints, and other indolent tumors. (See *Emplastrum Ammoniaci cum Hydrargyro*.) It is given in substance, in pill or emulsion. The latter form, however, is preferable. (See *Emulsum Ammoniaci*, U. S. 1890.)

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

Off. Prep.—*Emplastrum Ammoniaci cum Hydrargyro*, *Br.*; *Mistura Ammoniaci*, *Br.*; *Pilula Ipecacuanhæ cum Scilla*, *Br.*; *Pilula Scillæ Composita*, *Br.*

AMMONII BENZOAS. U. S., Br.

AMMONIUM BENZOATE

(am-mō'nī-bén'zō-ās)

"It should contain not less than 98 percent. of pure Ammonium Benzoate [$C_6H_5.COONH_4$], and should be kept in well-stoppered bottles," U. S. "This salt, $C_6H_5.COONH_4$, is produced by neutralizing benzoic acid with solution of ammonia." *Br.*

Ammonia Benzoas, Ammonium Benzolcum, Benzoas Ammonicus; Benzoate of Ammonia; Benzoate d'Ammoniaque, *Fr. Cod.*; Benzoësures Ammonium, Ammonium benzoat, *G.*; Benzoato amonico, *Sp.*

The process for the preparation of this salt was omitted in the 1880 U. S. revision. The process of U. S. 1870 is appended. "Take of Benzoic Acid two troyounces; Water of Ammonia three fluidounces and a half, or a sufficient quantity; Distilled Water four fluidounces.

Dissolve the Acid in three fluidounces and a half of the Water of Ammonia, previously mixed with Distilled Water; evaporate with a gentle heat, occasionally adding Water of Ammonia, if necessary, to maintain a slight excess of the alkali; then set aside to crystallize, and dry the crystals without heat." *U. S.* 1870.

Although the quantity of ammonia ordered in the formula is in excess, yet, from the feeble affinity between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate would be formed, if it were not that a little solution of ammonia is from time to time added during or near the close of the evaporation, so as to maintain the alkali in slight excess. The crystals, for the same reason, should be dried without heat. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by means of bibulous paper.

Properties.—"Thin, white, laminar crystals or a crystalline powder; odorless, or having a slight odor of benzoic acid, a saline, bitter, afterwards slightly acid taste, and gradually losing ammonia on exposure to the air. Soluble in about 10.5 parts of water and 25 parts of alcohol at 25° C. (77° F.), in 1.2 parts of boiling water, and in 7.6 parts of boiling alcohol. The salt fuses at 193° to 194° C. (379.4° to 381.2° F.), with decomposition, and when strongly heated emits vapors having the odor of ammonia and benzoic acid, and is finally completely volatilized. The aqueous solution of the salt is neutral, or very slightly reddens blue litmus paper. A saturated aqueous solution of Ammonium Benzoate affords with ferric chloride T.S. a flesh-colored precipitate, and when such a solution is gently heated with potassium hydroxide T.S. ammonia is evolved. If diluted nitric acid be added in slight excess to the aqueous solution of the salt (1 in 10), the precipitated benzoic acid, after collecting and washing, should respond to the tests of purity and identity given under *Acidum Benzoicum*, and the filtrate from this precipitate should not be affected by barium chloride T.S. (absence of *sulphate*), or by silver nitrate T.S. (absence of *chloride*). If the aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121)." *U. S.* "Soluble in 6 parts of cold water, in 30 of alcohol (90 per cent.), and in 8 of *glycerin*. It affords the reactions characteristic of ammonium salts. An aqueous solution yields a yellowish or flesh-colored precipitate when mixed with *test-solution of ferric chloride*. A strong aqueous solution to which a little *sulphuric acid* is added affords a crystalline precipitate of benzoic acid. It should yield no residue on heating to redness, and no characteristic reaction with the tests for

chlorides or sulphates. Its cold aqueous solution does not at once redden *solution of litmus* (absence of acid); on boiling the solution it slowly dissociates into benzoic acid and ammonia, and affords an acid reaction." *Br.* Gmelin states that by boiling its solution the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Hand-book*, xii. 38.) According to Lichtenstein, it deliquesces in the air. It gives a copious yellow precipitate with ferric salts, and is known to contain benzoic acid and ammonia, by depositing the former when the solution is acidulated with hydrochloric acid, and giving off the latter when it is heated with potassium hydroxide. According to Squire, the acid salt, which is that commonly met with in commerce, is less soluble than the official salt, requiring 60 parts of water and 12 of alcohol for solution. This is a decided objection to it.

Uses.—Ammonium benzoate is a slightly stimulant diuretic, which acts chiefly through its benzoic acid, it being decomposed by the gastric acids, which combine with the ammonia, while the benzoic acid is absorbed, and passes out through the kidneys in the form of hippuric acid. (See *Benzoic Acid*.) The salt has been found useful as an alternative diuretic, in chronic inflammation of the genito-urinary tract, and as a solvent of the *phosphatic deposits*, through the hippuric acid into which it is converted. It has been employed in *gouty affections* with a view to the removal of the deposits of sodium urate about the joints; but it has been shown to have no effect on the elimination of *uric acid*.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.), which may be taken dissolved in water.

AMMONII BROMIDUM. U. S., Br.

AMMONIUM BROMIDE

(am-mō'nī-brō-mī-dūm)

$\text{NH}_4\text{Br} = 97.29$

"It should contain not less than 97 percent. of pure Ammonium Bromide, and should be kept in well-stoppered bottles." *U. S.* "This salt, NH_4Br , is formed by neutralizing hydrobromic acid with a solution of ammonia." *Br.*

Ammonium Bromatum; Bromhydrate d'Ammoniaque, *Fr. Cod.*; Bromure d'Ammonium, *Fr.*; Ammonium bromatum, *P. G.*; Ammonium bromid, *Brom-Ammonium, G.*; Bromuro di ammonio, *It.*; Bromuro amonico, *Sp.*

Ammonium bromide may be made by dissolving bromine in ammonia water; but the *U. S. Pharm.* 1870 preferred the method of first forming solution of ferrous bromide, precipitating with ammonia water, separating by filtration the ferric oxide, and obtaining by evaporation the ammonium bromide from the solution. This process is similar to that by which potassium bromide is prepared. According to Procter, a still better method consists in adding to bromine and water sufficient solution of ammonium sul-

phide to discharge the color, filtering to separate the sulphur, and then evaporating to dryness. Charles Rice (*A. J. P.*, 1873, p. 249) recommends making ammonium bromide by double decomposition between hot solutions of potassium bromide and ammonium sulphate, assisting the precipitation of potassium sulphate by alcohol. W. H. Pile (*Proc. A. Ph. A.*, 1874, p. 434) published a simple process for this salt. Pour the bromine (one pound) carefully into four times its weight of distilled water in a stone jar, add *very gradually* about one quart of solution of ammonia, cover the top of the jar with a glass plate when vapors arise, and when all the ammonia has been added, and the solution is free from the odor of bromine, it is evaporated and the salt granulated; the yield is about twenty ounces.

Properties.—Ammonium bromide may be obtained in colorless crystals, but the official salt is also a white, crystalline powder. Whether in crystals or in powder, on exposure to the air it gradually becomes yellowish, in consequence of a partial decomposition, by which hydrobromic acid appears to be liberated, as it now changes litmus red. The salt has a saline, pungent taste. Exposed to heat, it sublimes unchanged. It is officially described as in "colorless, transparent, prismatic crystals, or a white, crystalline powder; odorless, of a pungent, saline taste, and permanent in dry air. Soluble in 1.2 parts of water, and in 12.5 parts of alcohol at 25° C. (77° F.), in 0.7 part of boiling water, and in 9 parts of boiling alcohol. When heated, Ammonium Bromide volatilizes completely, without fusing. An aqueous solution of the salt slightly reddens blue litmus paper." *U. S.* It is sparingly soluble in ether, and is incompatible with acids, acid salts, and spirit of nitrous ether.

"When the aqueous solution is gently heated with potassium hydroxide T.S., ammonia is evolved. Silver nitrate T.S. produces a yellowish-white precipitate, insoluble in nitric acid or in a moderate excess of ammonia water. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, and if chlorine water, which has been diluted with an equal volume of water, be cautiously introduced drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodide*). If a few drops of diluted sulphuric acid be brought in contact with a little of the powdered salt on a porcelain plate, the salt should not at once assume a yellowish color (absence of *bromate*). An aqueous solution of the salt (1 in 100) should not at once assume a blue color with potassium ferrocyanide T.S. (limit of *iron*). Ten Cc. of an aqueous solution of Ammonium Bromide (1 in 20), when acidulated with acetic acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric

acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 3 Gm. of the salt be dissolved in sufficient water to measure 100 Cc., then 10 Cc. of this solution, after the addition of a few drops of potassium chromate T.S., should require not more than 31.6 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red coloration." *U. S.* "0.5 gramme of the dry salt dissolved in water should require not more than 51.8 and not less than 51.1 cubic centimetres of the *volumetric solution of silver nitrate* for complete precipitation (limit of impurities). It should yield no residue on being heated to redness, no characteristic reaction with the tests for lead, iron, bromates, iodides, or nitrates, and not more than the slightest reactions with the tests for sulphates or chlorides." *Br.*

Uses.—This bromide resembles potassium bromide in its physiological powers, but has a less depressing effect upon the arterial and muscular systems. It is certainly superior to potassium bromide in most cases of *epilepsy* and even of minor *neuroses*.

Dose, 15 grains (1 Gm.), or one to two drachms a day (3.9 to 7.7 Gm.), in dilute solution.

AMMONII CARBONAS. U. S., Br.

AMMONIUM CARBONATE

(ām-mō'nī-i cār'bq-nās)

"It should contain not less than 97 percent. of a mixture of Acid Ammonium Carbonate $[\text{CO}(\text{OH})\text{ONH}_4]$ and Ammonium Carbamate $[\text{CO}(\text{NH}_2)\text{ONH}_4]$ and should yield not less than 31.58 percent. of ammonia gas. It should be kept in well-stoppered bottles, in a cool place. For dispensing purposes, only the translucent portions should be used." *U. S.* "A variable mixture of ammonium hydrogen carbonate, NH_4HCO_3 , with ammonium carbamate, $\text{NH}_4\text{H}_2\text{CO}_3$, produced on heating ammonium sulphate or chloride with calcium carbonate." *Br.*

Ammonie Carbonas, *Br.* 1867; Ammonie Sesquicarbonas, *London, Dub.*; Carbonas Ammonicus, *Sal Volatile Siccum*; Volatile Salt, *Sal Volatile*; Carbonate d'Ammoniaque, *Fr. Od.*; Alcali volatil concret, *Sal volatil d'Angleterre, Fr.*; Ammonium carbonicum, *P. G.*; Ammonium-carbonat, *Kohlensaures Ammonium*, *Pflüchtiges Laugensalz*, *Reines Hirschhornsalz*, *G.*; Carbonato di ammonio, *It.*; Carbonato amonico, *Sp.*

There have been many methods of obtaining ammonium carbonate, in all of which the ammonia originated in organic decomposition. It was probably originally prepared from putrid urine, and it is sometimes made in Scotland now from this source. A patent was taken out in England for manufacturing it from guano, and another for making it by the direct combination of its constituents, the carbon dioxide and ammoniacal gases being introduced simultaneously into leaden chambers. (*Chem. News*, Dec. 29, 1865.) At present the salt is manufactured by

subliming a mixture of either the chloride or the sulphate with chalk. Ammonium chloride and chalk (calcium carbonate) are heated together in iron pots or retorts, and sublimed into large earthen or leaden receivers. By the reciprocal action of the salts employed, the carbon dioxide of the chalk unites with the ammonia of the chloride, generating ammonium carbonate, and the hydrochloric acid with the lime, forming water and calcium chloride. The carbonate and water sublime together as hydrated ammonium carbonate, and the residue is calcium chloride. The relative quantities of chalk and ammonium chloride, for mutual decomposition, are 50 of the former and 53.5 of the latter, or one molecule of each. But a great excess of chalk is usually taken, in order to insure the perfect decomposition of the ammonium chloride, any redundancy of which would sublime with the carbonate and render it impure.

Ammonium sulphate may be substituted for the chloride with much economy, as was shown by Payen. This double decomposition between ammonium sulphate and calcium carbonate takes place in the dry way only,—that is, by sublimation. In the wet way, the double decomposition is reversed, ammonium carbonate and calcium sulphate reacting so as to form ammonium sulphate and calcium carbonate. Large quantities of this carbonate are manufactured indirectly from *coal gas liquor* and *bone spirit*, the ammoniacal products in these liquors being converted successively into ammonium sulphate, chloride, and carbonate. (See *Ammonii Chloridum*.) The salt as first obtained has a slight odor of tar, and leaves a blackish carbonaceous matter when dissolved in acids. Hence it requires to be purified, which is effected in iron pots surmounted with leaden heads. The American carbonate has almost supplanted the English article, which was formerly used exclusively.

Properties.—The official salt is described as in “white, hard, translucent, striated masses, having a strong odor of ammonia without empyreuma, and a sharp, saline taste. On exposure to the air, the salt loses both ammonia and carbon dioxide, becoming opaque, and is finally converted into friable, porous lumps, or a white powder.” *U. S.* (Acid ammonium carbonate). Commercial ammonium carbonate, recently prepared, is in white, translucent masses, consisting of Ammonium Bicarbonate (Acid Carbonate) and Carbamate.

“Slowly but completely soluble in about 4 parts of water at 25° C. (77° F.); it is decomposed by hot water, with the elimination of carbon dioxide and ammonia. By prolonged boiling with water, the salt is completely volatilized. Alcohol dissolves the carbamate, and leaves the acid carbonate. When heated, Ammonium Carbonate is completely volatilized, without charring. The aqueous solution effervesces with acids, and shows an alkaline reaction with red litmus paper. The aqueous solution of the salt (1 in 20), when slightly supersaturated with hy-

drochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Another portion of this solution should not be affected by barium chloride T.S. (absence of *sulphate*). The aqueous solution of the salt (1 in 20), on the addition of a slight excess of silver nitrate T.S., and subsequent supersaturation with nitric acid, should neither assume a brown color (absence of *thiosulphate*), nor become more than slightly opalescent within two minutes (limit of *chloride*). If an aqueous solution containing 1 Gm. of the salt be slightly supersaturated with nitric acid, and then evaporated to dryness on a water-bath, it should afford a colorless and odorless residue, which, upon gentle ignition, should be completely volatilized (absence of *empyreumatic* or *non-volatile matters*). If 2 Gm. of unaltered, translucent Ammonium Carbonate be dissolved in a mixture of 50 Cc. each of distilled water and normal sulphuric acid V.S., boiled for a few minutes to expel the liberated carbon dioxide, and then cooled, not more than 12.7 Cc. of normal potassium hydroxide V.S. should be required for exact neutralization, litmus T.S. being used as indicator.” *U. S.* “Exposed to the air it becomes covered with a white efflorescence which should be only superficial; this should be scraped off before the salt is used for dispensing purposes. It affords the reactions characteristic of ammonium salts and of carbonates. Each gramme dissolved in 40 cubic centimetres of water should require for neutralization at least 18.7 cubic centimetres of the *volumetric solution of sulphuric acid*. It should yield no residue on being heated to redness, and not more than the slightest reactions with the tests for chlorides or sulphates. When its aqueous solution is neutralized with an acid and evaporated to dryness, the residue should be colorless and odorless (absence of tarry matters).” *Br.* If commercial ammonium carbonate be treated with 90 or 91 per cent. alcohol, it is decomposed into the two salts of which it is composed, ammonium carbamate going into solution while the acid ammonium carbonate remains undissolved. This latter compound also remains undissolved when the commercial carbonate is treated with an amount of water insufficient for complete solution. The result of the complete solution of the commercial salt in water is a mixture of acid and neutral carbonates, the carbamate having been decomposed according to the reaction:

When long or insecurely kept, it gradually passes into a bicarbonate, becoming opaque and friable, and falling into powder. When heated on a piece of glass, the commercial carbonate should evaporate without residue, and, if turmeric paper held over it undergoes no change, it has passed into bicarbonate. As prepared from

coal gas liquor, it sometimes contains traces of tarry matter, which give a dark color to its solution in acids, but a refined carbonate, made by resubliming the commercial article, is now in the market, and this alone should be dispensed in preparations for internal use. When it is saturated with nitric acid, neither barium chloride nor silver nitrate causes a precipitate. The non-action of these tests shows the absence of ammonium sulphate and chloride. The presence of lead in small quantities was detected by Bennett in commercial ammonium carbonate (*C. D.*, 1904, 203). It is decomposed by acids, the fixed alkalies and their carbonates, lime water and magnesia, solution of calcium chloride, alum, acid salts such as potassium bitartrate and bisulphate, solutions of iron (except the iron and potassium tartrate and analogous preparations), corrosive sublimate, lead acetate and subacetate, and ferrous and zinc sulphates. Traces of chlorine have been noticed in some samples of commercial carbonate, and a sublimed salt which had been sold as carbonate, was *devoid of odor*, hard, crystalline, yet having the external appearance of carbonate, and was proved by Bridges to be anhydrous ammonium bicarbonate. (*A. J. P.*, Nov. 1874). Although much inferior to the official compound, this salt is often found in the market. For papers on testing commercial ammonium carbonate see *A. J. P.*, 1890, p. 500, by G. M. Beringer; also *Ph. Era*, 1889, p. 417, by Charles C. Abbey.

Uses.—Locally applied ammonium carbonate is an irritant and an irritant poison in overdoses. When administered in therapeutic doses it is a powerful cardiac stimulant, acting not so rapidly and fugaciously as the solutions of ammonia, but still in a very prompt and temporary manner. It is employed in low conditions of the system as a stimulant, but it should always be remembered that its influence lasts for only a short time, and that there is reason for believing that when continuously given it is apt to impair the crasis of the blood. It is probably eliminated in part by the lungs, and certainly is a stimulant to the respiratory centres. It seems also to exert some influence upon the pulmonary mucous membrane, and is largely employed in *adynamic pneumonia* and *bronchitis*, in the last stages of *phthisis*, etc. In some of these cases it does good by increasing muscular power and aiding in the expulsion of the sputa.

Coarsely bruised with the addition of half its bulk of stronger ammonia water, and scented with oil of lavender, it constitutes the common *smelling-salts*, so much used as a nasal stimulant in *syncope* and *hysteria*.¹ It should never

be given in powder or in pill, on account of its volatile nature and its irritant action on the mucous membrane.

Ammonium carbonate is sometimes employed in making effervescing draughts, 20 grains of the salt requiring for this purpose 6 fluidrachms of lemon juice, 24 grains of citric acid, or 25½ grains of tartaric acid.

Dose, five to ten grains (0.32 to 0.65 Gm.) every two hours.

AMMONII CHLORIDUM. U. S., Br.

AMMONIUM CHLORIDE [*Ammonium Muriate*,
Muriate of Ammonia]

(ām-mō'ni-i chlō'rj-dūm)

$\text{NH}_4\text{Cl} = 53.11$

"It should contain not less than 99.5 percent. of pure Ammonium Chloride." *U. S.* "This salt, NH_4Cl , may be formed by neutralizing crude solution of ammonia or ammonium carbonate with hydrochloric acid, and purifying the product." *Br.*

Ammonium Muriaticum, s. Hydrochloratum, Chloruretum Ammonicum, Sal Ammoniacum, Ammonias Hydrochloras, s. Murias; Sal Ammoniac, Hydrochlorate of Ammonia; Chlorhydrate d'Ammoniaque, *Fr. Cod.*; Hydrochlorate d'Ammoniaque, Muriate d'Ammoniaque, Sel Ammoniac, Chlorure d'Ammonium, Chlorure d'Ammonium pur, *Fr.*; Ammonium Chloratum, *P. G.*; Ammoniumchlorid, Salmiak Chlorammonium, Reiner (gereinigter) Salmiak, *Gr.*; Chloruro di ammonio, Sale ammoniaco, *It.*; Cloruro amonico, Sal amoniaco, *Sp.*

In the U. S. Pharmacopœia of 1870 both the crude and the purified ammonium chloride were official, under the names *Ammonii Chloridum* and *Ammonii Chloridum Purificatum*. The U. S. P. (8th Rev.) recognizes but one, *Ammonii Chloridum*, but it transfers this title, which formerly was given to the crude sal ammoniac, to the purified salt, without giving a process for preparing it. The U. S. P. 1870 process is as follows: "Take of Chloride of Ammonium, in small pieces, *twenty troyounces*; Water of Ammonia *five fluidrachms*; Water *two pints*. Dissolve the Chloride of Ammonium in the water, in a porcelain dish, with the aid of heat; add the Water of Ammonia, and continue the heat for a short time; filter the solution while hot, and evaporate to dryness, with constant stirring at a moderate heat, until it granulates." *U. S.* 1870.

This process is used to free the salt from ferric chloride, a frequent impurity of the crude product, derived from the subliming vessels.

Ammonium chloride originally came from Egypt, where it was obtained by sublimation from the soot resulting from the burning of camels' dung, which is used in that country for fuel, and it is still to be found in the Indian

¹ In Mounsey's recipe for the English *Preston salts* the essence to be added to the carbonate is made as follows: Take oil of cloves, 30 min.; oil of lavender 1 fl. dr.; oil of bergamot 2½ fl. dr.; stronger ammonia water (sp. gr. 0.880) 10 fl. dr. Mix. The bottles are to be filled with ammonium carbonate, half with the salt coarsely bruised, and the remainder with it in fine powder; and then as much of the above essence as the salt will readily absorb is to be added. (*P. J.*, xlii. 628.)

bazaars in an impure state as it has been obtained from the unburnt residue in the interior of brick-kilns in which camel's manure is used for fuel. It has long been known in China, where it is obtained from the water of certain volcanic springs, and exists in commerce in various states of purity. It is found in the fumeroles of Vesuvius, Etna, Hecla, and other volcanoes, as well as in the cracks and fissures in recent lava streams.

Preparation.—At present ammonium chloride is derived from two principal sources, the ammoniacal liquor, called *gas liquor*, found in the condensing vessels of coal gas works, and the brown, fetid ammoniacal liquor, known under the name of *bone-spirit*, which is a secondary product, obtained from the destructive distillation of bones, in the manufacture of bone black. These two liquors are the chief sources of ammoniacal compounds, for they are both used to procure ammonium sulphate, and this salt is employed directly or indirectly for obtaining all the other salts of ammonium. A third source of increasing importance is its production as a by-product in ovens for coking coal. Other sources are stale urine, coal soot, guano, peat, and bituminous schist.

Gas liquor contains ammonium carbonate, cyanide, sulphide, and sulphate, but principally the carbonate. It is saturated with sulphuric acid, and the solution obtained, after due evaporation, furnishes brown crystals of ammonium sulphate. These are then sublimed with sodium chloride in iron pots lined with clay and furnished with a leaden dome or head. By the mutual action of the sulphate and chloride, there are formed ammonium chloride which sublimes, and sodium sulphate which remains behind. Thus:

Gas liquor is usually distilled with lime with the aid of column stills, whereby a relatively pure and strong solution of ammonia is obtained.

This may be further purified, however, from empyreumatic matter by treatment with potassium permanganate and then driven over by heat and absorbed in hydrochloric acid. In this way, as the solution becomes concentrated, the sal ammoniac crystallizes out in the bottom of the leaden tanks in which the absorption takes place. Impure sal ammoniac may be purified either by crystallization or by sublimation. In the latter case the sal ammoniac is placed in an iron subliming pot coated with a composition of clay, sand, and charcoal and covered with a dome of lead. These pots are sometimes sufficiently large to hold 500 pounds. A gentle fire is kept up under the subliming pot for seven or eight days, when, the dome having cooled down, and the sal ammoniac somewhat contracted, so as to loosen from the sides, the dome is thrown off from the iron pot, and about two or three hundred-weight of white, semitransparent sal ammoniac is knocked off in cakes.

In the destructive distillation of bones for making bone black, the distilled products are

the bone spirit already mentioned, being chiefly an aqueous solution of ammonium carbonate, and an empyreumatic oil, called *animal oil*. Ammonium chloride may be obtained from the bone spirit in the manner just described for procuring it from gas liquor. Sometimes, however, the ammonium sulphate is not made by direct combination, but by digesting the bone spirit with ground plaster of Paris. By double decomposition, ammonium sulphate and calcium carbonate are formed. The ammonium sulphate is then converted into the chloride by sublimation with common salt. The chloride "may be formed by neutralizing hydrochloric acid with ammonia or carbonate of ammonium, and evaporating to dryness." *Br.*, 1885.

Other processes have been proposed or practised for obtaining ammonium chloride. For an account of the manufacture of ammoniacal salts, and for a list of the patents issued in Great Britain, since 1827, for their preparation, the reader is referred to *P. J.*, xii. 20, 63, 113.

Properties.—Commercial ammonium chloride is a white, transparent, tough, fibrous salt, occurring in large cakes about two inches thick, convex on one side and concave on the other, due to the shape of the dome of the subliming apparatus; the pieces are frequently tinged on the surface with iron stains, owing to the contact with the iron dome. It has a pungent, saline taste, but no odor. Its sp. gr. is 1.45. This salt is very difficult to powder in the ordinary way. Its pulverization, however, may be readily effected by making a boiling saturated solution of the salt and stirring it as it cools. The salt is thus made to granulate, and in this state, after draining from the remaining solution and drying, may be easily powdered. At a red heat it sublimes without decomposition or residue. Exposed to a damp atmosphere it becomes slightly moist. It has the property of increasing the solubility of corrosive sublimate in water. It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths,—the former disengaging hydrochloric acid, the latter ammonia, both sensible to the smell. Ammonium chloride is usually employed for obtaining gaseous ammonia, which is conveniently disengaged by lime. It is incompatible with lead acetate and silver nitrate, producing precipitates respectively of lead and silver chlorides.

Ammonium chloride is little subject to adulteration. If not entirely volatilized by heat, and if incompletely soluble in water, it contains impurity. As ordinarily prepared, it contains ferrous chloride, and this may be detected by boiling a small portion of a saturated solution of the salt with a drop or two of nitric acid, and then adding potassium ferrocyanide, when the characteristic blue color occasioned by iron will be produced. If the salt is entirely volatilized by heat, and yet produces a precipitate with barium chloride, the presence of ammonium sulphate is indicated. The description and tests of the official salt are as follows:

"A white, crystalline powder, without odor, having a cooling, saline taste, and permanent in the air. Soluble in 2 parts of water, in 50 parts of alcohol, and in 5 parts of glycerin, at 25° C. (77° F.), and in one part of boiling water. On ignition, Ammonium Chloride is completely volatilized, without charring. The aqueous solution of the salt (1 in 20) in ice-cold water, should not redden blue litmus paper at once; it affords, with silver nitrate T.S., a white, curdy precipitate, which is soluble in ammonia water. The aqueous solution, when gently heated with potassium hydroxide T.S., evolves ammonia. The aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121), nor should it be affected by barium chloride T.S. (*sulphate*), nor diluted sulphuric acid (*barium*), nor ammonium oxalate T.S. (*calcium*). When acidulated with hydrochloric acid, the solution should not assume a red color on the addition of a few drops of ferric chloride T.S. (absence of *sulphocyanate*). Twenty Ce. of the aqueous solution of the salt (1 in 20) should not at once assume a blue color on the addition of 5 drops of potassium ferrocyanide T.S. (limit of *iron*). If to 1 Gm. of the salt a little nitric acid be added, and the mixture evaporated to dryness in a porcelain dish on a water-bath, a white residue should be obtained, which, when more strongly heated, should be volatilized (absence of *empyreumatic* or *non-volatile substances*). If 1 Gm. of Ammonium Chloride be dissolved in sufficient distilled water to measure 100 Ce., then 10 Ce. of this solution should, after the addition of five drops of potassium chromate T.S., require not less than 18.7 Ce. of tenth-normal silver nitrate V.S. to produce a permanent red color." *U. S.* "It should yield no residue on being heated to redness, and no characteristic reaction with the tests for lead, copper, arsenium, calcium, carbonates, or nitrates, and only the slightest reactions with the tests for iron, or for sulphates. Its aqueous solution should not give a blood-red coloration with *test-solution of ferric chloride* (absence of thiocyanates)." *Br.*

Uses.—Ammonium chloride has the stimulant properties of ammonia, and probably differs little in its physiological powers from the carbonate, but it is believed by many to be less fugacious in its action and to be less stimulant to the circulation than is the latter salt. Clinical experience has also led to a somewhat particular use of it in diseases. It is one of the most employed of the stimulant expectorants in the advanced stages of *acute bronchitis* and in *chronic bronchitis*, also in *catarrhal pneumonia*. It has been very highly recommended of late years in *chronic hepatic torpor* and *engorgement*, and even in *acute hepatitis*, by W. Stewart, who gives twenty grains of it three times a day and continues its use for weeks. We have seen *catarrhal jaundice* apparently very much benefited by it. Many years ago it was a favorite remedy as a resolvent in

chronic glandular enlargements, but at present it is rarely so employed. There is much testimony as to the value of ammonium chloride in certain obscure nervous affections, especially *hemisphagia*, *ovaralgia*, *dysmenorrhœa*, *sciatica*, and various other neuralgic disorders. The usual expectorant dose of the chloride is five to ten grains (0.32 to 0.65 Gm.) every two hours, administered in sweetened mucilage; but formerly in *prostatic* and other *glandular enlargements* it was recommended to increase the dose until half an ounce a day was ingested. When such amounts are given, the remedy is prone to produce disordered digestion, a miliary eruption, profuse sweats, and scorbutic symptoms.

The vapor of ammonium chloride has been administered by inhalation, employed several times a day, in *chronic catarrh*, with marked advantage by Gieseler of Germany. Hermann Beigel of London, strongly recommends its inhalation in the nascent state, resulting from a mixture of the two gases composing it. Three bottles are used, one containing ammonia water, the second an equivalent quantity of liquid hydrochloric acid, and the third half filled with water, connected with the first two by tubes, and supplied itself with a tube for inhalation. By inhalation the patient draws the two gases from their respective bottles into the third, where they combine to form ammonium chloride, which is freed from any excess of either gas by the water. Another mode of inhaling ammonium chloride is in *spray*, by means of the atomizer; ten to twenty grains are dissolved for the purpose in a fluidounce of water.

Dose, five to ten grains (0.32 to 0.65 Gm.).

Off. Prep.—Trochisci Ammonii Chloridi, *U. S.*

AMMONII IODIDUM. U. S.

AMMONIUM IODIDE

(am-mō'ni-i i-ōd'ī-dūm)

$\text{NH}_4\text{I} = 143.83$

"It should contain not less than 97 percent, of pure Ammonium Iodide, and should be kept in small amber-colored, well-stoppered vials, protected from light. When deeply colored, the salt should not be dispensed, but it may be deprived of free iodine by adding to its concentrated aqueous solution sufficient ammonium sulphide T.S. to render it colorless, then filtering, and evaporating in a water-bath to dryness." *U. S.*

Iodhydrate d'ammoniaque, *Fr. Cod.*; Iodure d'Ammonium. *Fr.*; Ammonium iodatum, Jodammonium, *G.*; Ioduro amonico, *Sp.*

No process is given in the *U. S. P.* (8th Rev.) for this salt; it was formerly prepared according to the method of John A. Spencer of London, the formula for which is as follows: Add to a portion of iodine, placed in a flask with a little water, a solution of ammonium sulphy-

drate, until the mixture loses its red color, and is turbid from the separation of sulphur only. Shake the flask, which causes the sulphur, for the most part, to agglomerate, and having poured off the liquid, boil it until all odor of hydrogen sulphide and of ammonia is lost. Then filter the liquid, and, constantly stirring, evaporate it, first with a naked flame until it becomes pasty, and then in a water bath until it forms a dry salt. In 1864 (*A. J. P.*, May, 1864), Jacobson proposed a process in which double decomposition between solutions of ammonium sulphate and potassium iodide was employed. James F. Babcock (*Proc. A. Ph. A.*, 1866) stated that on trial of the first of the above processes, and of all others in which hydrogen sulphide or an alkaline sulphide was employed, the resulting ammonium iodide retained a portion of sulphur, which caused its color to change with time to yellow and ultimately to brown, and rendered it unfit for the accurate solutions required in photography. Having tried also other formulas, which he found objectionable, he at length satisfied himself that Jacobson's process, above described, was the best in use, and with slight modifications would yield an absolutely pure product.

In a former edition of the Dispensatory may be found the exact process finally adopted by Babcock. It is substantially that which was official in U. S. P. 1870¹ and is in close accord with that of Jacobson. The object of the first step of the process is sufficiently evident. After the double decomposition has occurred, the alcohol is added to complete the precipitation of the potassium sulphate; the pouring of alcohol upon the cotton filter is to remove completely from the sulphate all of the iodide. As made by this process, ammonium iodide always contains a minute proportion of potassium sulphate. Charles Rice (*A. J. P.*, 1873, p. 249) calls attention to the fact that the process official in U. S. P. 1870 is deficient in the amount of ammonium sulphate required, and therefore wasteful of the more expensive iodide; instead of one ounce of ammonium sulphate the quantity should be 867 grains. The view taken by Charles Rice, however, is that the reaction takes place between single molecules of the respective salts, which is no doubt correct, whereas the view of the Pharmacopœia committee was that two molecules of the iodide reacted with one of ammonium sulphate,

¹ "Take of Iodide of Potassium, in coarse powder, four *troynounces*; Sulphate of Ammonium, in coarse powder, a *troynounce* [this should be 867 grains]; Boiling Distilled Water, two *fluidounces*; Alcohol, Water, each, a *sufficient quantity*. Mix the salts, add them to the Boiling Water, stir well, and allow the mixture to cool; then add a *fluidounce* of Alcohol, mix well, and reduce the temperature, by a bath of iced water, to about 40°; throw the mixture into a cool glass funnel, stopped with moistened cotton, and, when the clear solution has passed, pour upon the salt a *fluidounce* of a mixture containing two parts of Water and one part of Alcohol. Lastly, evaporate the solution rapidly to dryness, stirring constantly; and preserve the residue in a well-stoppered bottle." U. S. 1870.

Properties.—Ammonium iodide occurs in "minute, colorless, cubical crystals, or a white, granular powder, without odor when colorless, but emitting a slight odor of iodine when colored, and having a sharp, saline taste. The salt is very hygroscopic, and soon becomes yellow or yellowish-brown on exposure to the air and light, owing to the loss of ammonia and the liberation of iodine. Soluble in 0.6 part of water, and in 9 parts of alcohol at 25° C. (77° F.); in 0.43 part of boiling water, and in 3.7 parts of boiling alcohol. When heated on platinum foil, Ammonium Iodide evolves vapor of iodine, and volatilizes completely without fusing. The aqueous solution of the salt shows a neutral reaction to litmus paper, and when gently heated with potassium hydroxide T.S., evolves ammonia. If to 5 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chlorine water be added, iodine will be liberated and impart to the solution a light reddish-brown color. On agitating the mixture with a few drops of chloroform, the latter will acquire a violet color. Ten Cc. of the aqueous solution of Ammonium Iodide (1 in 20), when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate T.S. (absence of *barium*). An aqueous solution of the salt (1 in 100) should not at once assume a blue color with potassium ferrocyanide T.S. (limit of *iron*), nor, after being agitated with 1 Cc. of chloroform, should the latter assume a violet color (limit of *free iodine*). The aqueous solution of Ammonium Iodide (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 0.25 Gm. of the salt, dried at 100° C. (212° F.), be dissolved in 5 Cc. of ammonia water (10 percent.), the solution shaken with 16.9 Cc. of tenth-normal silver nitrate V.S., and the filtrate supersaturated with 5 Cc. of nitric acid, no cloudiness should make its appearance within ten minutes (absence of more than about 3 percent. of *chlorides* or *bromides*)." U. S.

Uses.—Ammonium iodide is employed, both externally and internally, as a resolvent, and resembles closely, in its action, iodine and potassium iodide. B. W. Richardson of London, has prescribed it, in the dose of from one to three grains, with considerable success, in *secondary syphilis, chronic rheumatism, incipient phthisis*, and in a variety of forms of *scrofulous disorder*, attended with glandular enlargements. Richardson found a liniment, made by dissolving half a drachm of the iodide in an ounce of glycerin, very efficacious in *enlarged tonsils*, applied every night with a large camel's-hair brush, and his practice has been followed to some extent by other members of the profession. Externally, this salt has been used as a substitute for potassium iodide. By Pennock it is considered a good remedy in certain cases of *lepra* and *psoriasis*, in the form of ointment, applied by friction in the quantity

of half an ounce, morning and evening. The proportions employed are from twenty grains to a drachm of the salt to an ounce of lard, the weaker preparation being used when the disease is recent, the stronger when it is chronic. As the iodide is decomposed by the air, the ointment should be kept in well-stoppered bottles.

Dose, three to five grains (0.20 to 0.32 Gm.).

AMMONII PHOSPHAS. Br.

AMMONIUM PHOSPHATE

(am-mō'nī-i phōs'phās)

$(\text{NH}_4)_2\text{HPO}_4 = 131.15$

"A salt, $(\text{NH}_4)_2\text{HPO}_4$, which may be obtained by neutralizing phosphoric acid with solution of ammonia." *Br.*

Ammonia Phosphas; Phosphate of Ammonia; Phosphas Ammonicus; Phosphate d'Ammoniaque, *Fr.*; Ammonium Phosphoricum; Phosphorsäures Ammoniak, *G.*

This salt was introduced into the 1880 U. S. P., but was dropped at the 1890 revision.

Preparation.—The salt commonly found in commerce is either this acid phosphate, or a mixture of the two acid salts. The official salt may be made by saturating the excess of acid in acid calcium phosphate by means of ammonium carbonate. Calcium phosphate is precipitated and ammonium phosphate obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. The method of obtaining the acid calcium phosphate is given under the head of sodium phosphate. (See *Sodii Phosphas*.) Ammonium phosphate prepared in this way is a white salt, crystallizing in six-sided tables, derived from oblique quadrangular prisms, efflorescent, insoluble in alcohol, and soluble in four parts of cold water. The solution has an alkaline somewhat saline taste, and an alkaline reaction, and gives off ammonia when heated.

The other acid phosphate, $\text{NH}_4\text{H}_2\text{PO}_4$, is obtained by boiling a solution of either of the other salts so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water. (Bridges.) In a specimen of the common ammonium phosphate of commerce which came under our notice, we recognized both the tabular crystals of the phosphate with two molecules of ammonium, having a saline slightly acid taste, and neutral in reaction, and the prisms of the acid salt, with a sour and saline taste and a decidedly acid reaction.

The variety of phosphoric acid employed in this formula is the tribasic, which forms three salts with ammonia, one containing three atoms of ammonium without basic hydrogen, which is called the neutral phosphate, the second, two molecules of ammonium and one of basic hydrogen, forming an acid phosphate, and the third, one molecule of ammonium and two of

basic hydrogen, forming also an acid phosphate. The second of these is the one intended by the U. S. (1880) and British Pharmacopœias, and is represented by the formula $(\text{NH}_4)_2\text{HPO}_4$. To prepare it, a constant excess of ammonia must be maintained, and this is done by strict compliance with the process, if the materials are of due strength. Without such a precaution, more or less of the more acid phosphate would be generated, in consequence of the escape of the alkali.

Properties.—Hydrogen di-ammonium phosphate, which is the official salt, occurs in "colorless, translucent, monoclinic prisms, losing ammonia on exposure to dry air, without odor, having a cooling, saline taste and a neutral or faintly alkaline reaction. Soluble in 4 parts of water at 15° C. (59° F.), in 0.5 part of boiling water, but insoluble in alcohol. When strongly heated, the salt fuses, afterwards evolves ammonia, and at a bright red heat is wholly dissipated." *U. S.* 1880.

Tests.—"The aqueous solution of the salt, when heated with caustic potassa, evolves vapor of ammonia. Addition of test-solution of nitrate of silver to the aqueous solution produces a canary-yellow precipitate, soluble in nitric acid and in ammonia. The aqueous solution should remain unaffected by sulphide of ammonium, or, after being acidulated with hydrochloric acid, by hydrosulphuric acid (abs. of metals), or by test-solution of chloride of barium (sulphate). When acidulated with nitric acid, it should not be rendered turbid by test-solution of nitrate of silver (chloride). 2 Gm. of the salt dissolved in water and precipitated with test-mixture of magnesium, yields a crystalline precipitate, which, when washed with diluted water of ammonia, dried, and ignited, should weigh 1.68 Gm." *U. S.* 1880. This quantitative test was intended as a means of identifying the hydrogen di-ammonium salt. The British Pharmacopœia gives the following quantitative test. "When 2 grammes are dissolved in water, and solution of magnesium ammonio-sulphate is added in excess, a crystalline precipitate should be formed, which, after being well washed upon a filter with solution of ammonia diluted with an equal volume of water, and then dried and heated to redness, weighs 1.68 grammes. Its aqueous solution should yield no characteristic reaction with the tests for lead, copper, or arsenium, and only the slightest reactions with the tests for iron, chlorides, or sulphates." *Br.* The amount of the residue, which is magnesium pyrophosphate, indicates the quantity of phosphoric acid contained in the salt.

Uses.—This salt was first brought to the notice of the profession, as a remedy for *gout* and *rheumatism*, by T. H. Buckler (*A. J. M. S.*, 1846), and has since been so employed with apparently useful results.

Dose, from ten to forty grains (0.65 to 2.6 Gm.), three or four times a day, dissolved in a tablespoonful of water.

AMMONII SALICYLAS. U. S.

AMMONIUM SALICYLATE

(ám-mŏ'ní-i sál-i-cý'lās)

"It should contain not less than 98 percent. of pure Ammonium Salicylate [$\text{C}_6\text{H}_4(\text{OH})\text{COONH}_4$], and should be kept in well-stoppered bottles, protected from heat and light." U. S.

Ammonium Salicylicum; Salicylate d'Ammoniaque, *Fr.*; Ammoniumsalicylat, Salicylsäures Ammonium, *G.*

This salt was introduced into the U. S. Pharmacopœia (8th Rev.) and may be made by adding salicylic acid to ammonia water until the latter is nearly neutralized, then evaporating the solution (which should be slightly acid to litmus paper) and crystallizing. Care should be used to prevent contamination with iron, which would give the product a pinkish or reddish tinge, and overheating, which would cause decomposition, evidenced by a phenol-like odor.

Properties.—Ammonium salicylate is officially described as in "colorless, lustrous, monoclinic prisms, or plates, or a white, crystalline powder; odorless, and having at first a slightly saline, bitter taste, and a sweetish after-taste. Permanent in dry air. Soluble in 0.9 part of water, and 2.3 parts of alcohol at 25° C. (77° F.); freely soluble in boiling water and in 1 part of boiling alcohol. When heated, the salt fuses with decomposition, giving off inflammable vapors and an odor of phenol, and is finally completely volatilized. The concentrated aqueous solution should be colorless, it should reddens blue litmus paper, and when gently heated with potassium hydroxide T.S. evolves ammonia. Ferric chloride T.S., added to an excess of a concentrated solution of Ammonium Salicylate, produces a dark red precipitate, but imparts to a very dilute solution (1 in 100) a deep violet-blue color. If copper sulphate T.S. be added to the aqueous solution of the salt (1 in 20), a green color will be produced. If to 0.2 Gm. of the salt, contained in a test-tube, about 1 Cc. of concentrated sulphuric acid be added, and then cautiously about 1 Cc. of methyl alcohol, drop by drop, on heating the mixture to boiling, methyl salicylate will be formed, which can be recognized by its odor. If an aqueous solution of Ammonium Salicylate (1 in 20) be acidulated with hydrochloric acid and filtered, the filtrate should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). If diluted nitric acid be added in slight excess to the aqueous solution of the salt (1 in 10), the precipitated salicylic acid, after collecting and washing, should respond to the tests of purity and identity given under *Acidum Salicylicum*." U. S.

Uses.—Ammonium Salicylate is the best of the salicylates for ordinary use in *rheumatism*, being less depressing and nauseating than the official sodium salt.

Dose, ten to twenty grains (0.65 to 1.3 Gm.).

AMMONII VALERAS. U. S.

AMMONIUM VALERATE [Ammonii Valerianas, Pharm. 1890; Ammonium Valerianate]

(ám-mŏ'ní-i vāl'ē-rās)

"It should contain not less than 98 percent. of pure Ammonium Valerate [$\text{C}_5\text{H}_9\text{COONH}_4$], and should be kept in well-stoppered bottles." U. S.

Valerianate d'Ammoniaque, *Fr. Cod.*; Baldriansäures (Valeriansäures) Ammonium, Ammoniumvalerianat, *G.*; Valerianato amonico, *Sp.*

A process for preparing this salt is no longer official; that of the U. S. P. 1870 will be found in the U. S. D., 18th edition, p. 163.

Ammonium valerate was introduced into the U. S. Pharmacopœia of 1860; much difficulty was experienced by manufacturing chemists in procuring a crystallized ammonium valerate, until, after a series of experiments, B. J. Crew of Philadelphia, ascertained that it was necessary to employ the *monohydrated* valeric acid, as the ordinary acid with three molecules of water could not be successfully used for the purpose. The official formula of 1870 was based upon that of Crew, published in the *A. J. P.* (1860, p. 109). In this formula the monohydrated valeric acid, procured by a special process (see *Valeric Acid*), is saturated with gaseous ammonia obtained in the usual manner from a mixture of ammonium chloride and lime. The saturation is known to have been effected when litmus paper is no longer acted on. During the operation heat is developed sufficient to prevent premature crystallization, and, when the saturation is completed, nothing more is necessary than to allow the solution to cool. Crystallization soon begins, and in a few hours the contents of the vessel become a nearly solid mass of crystals; these should be thoroughly drained, and, without unnecessary exposure, at once transferred to well-stoppered bottles.

Properties.—Thus prepared, ammonium valerate is in snow white, pearly, four-sided, tabular crystals, perfectly dry, of an offensive odor like that of valeric acid, and a sharp sweetish taste. Instead of liquefying whenever exposed to the air, as happened to the salt formerly procured, it undergoes this change only in a moist atmosphere, and effloresces when the air is dry. It is very soluble in water, ether, and alcohol. Exposed to heat it is in great measure volatilized unchanged; but a small portion, by giving off a part of its ammonia, is converted into the acid valerate. Hager (*Ph. Centralh.*, 1879, p. 465) states that commercial ammonium valerate is always the acid salt, as is proved by the acid reaction and the strong rotation of the crystals when placed upon cold water; the neutral salt is obtained only with difficulty, is in prismatic crystals, and is easily liquefied by moderate temperatures. It is officially de-

scribed as in "colorless, or white, quadrangular plates, emitting the odor of valeric acid, of a sharp and sweetish taste, and deliquescent in moist air. Very soluble in water and in alcohol; also soluble in ether. When heated, the salt fuses, gives off vapor of ammonia and of valeric acid, and is finally completely volatilized. The aqueous solution shows an acid reaction to blue litmus paper, and, when gently heated with potassium hydroxide T.S., evolves ammonia. If a concentrated, aqueous solution of Ammonium Valerate be slightly supersaturated with sulphuric acid, an oily layer of valeric acid will rise to the surface. If a neutral solution of the salt be completely precipitated by ferrie chloride T.S., the filtrate should not possess a deep red color (absence of acetate). The aqueous solution of the salt (1 in 20), when slightly acidulated with hydrochloric acid and filtered through a small, wetted filter, should not respond to the Time-Limit Test for heavy metals (See PART III, Test No. 121)." U. S.

Uses.—Ammonium valerate is not poisonous. Given to dogs in the dose of 150 grains, it produced no inconvenience. As a therapeutic agent it was first brought to the notice of the profession, in 1856, by Délat of Paris in the form of a solution by Pierlot, an apothecary of Paris. Since then it has been used in various diseases, principally of the nervous system, such as *hysteria*, *epilepsy*, *chorea*, *neuralgia*, and is certainly useful in various mild functional nervous affections, but in such grave maladies as epilepsy it is powerless. The drug may be conveniently administered in coated pills, or in capsules. *Pierlot's solution*, mentioned above, should be made by dissolving a drachm of valeric acid in thirty-two drachms of distilled water, saturating the solution with ammonium carbonate, and adding to the salt formed forty grains of the alcoholic extract of valerian. According to Pierlot, the latter addition is necessary to preserve the preparation from change, for a simple solution of the ammoniacal salt is rapidly decomposed. It will keep still better if the extract, when added to the solution, be mixed with a fluidounce of diluted alcohol, with only 24 drachms of distilled water to preserve the measure. The solution of Pierlot is neutral, color brown, odor of valerian strong. It contains 1-25th of its weight of the pure salt. The dose is six to thirty minims (0.36 to 1.9 Cc.), given in water or on a lump of sugar.

Dose, of ammonium valerate, two to ten grains (0.13 to 0.6 Gm.).

BITTER ALMOND

ə-mġ'da-lə ə-mā'ra

"The ripe seed of *Prunus Amygdalus* Stokes, var. *amara* De Candolle (Fam. *Rosaceæ*)." U. S. "The ripe seed of *Prunus Amygdalus* Stokes, var. *amara*, Baillon." Br.

Semen Amygdali Amarum: Amandes amères, Fr. Cod.: Amygdale Amara, P. G.; Bittere Mandeln, G.; Mandorle amare, It.; Almendra amarga, It.

Amygdalus communis, Willd., *Sp. Plant.* ii. 982; Woodv., *Med. Bot.* p. 507, t. 183.—The almond tree rises usually from fifteen to twenty feet in height, and divides into numerous spreading branches. The leaves stand upon short stalks, are about three inches long and three-quarters of an inch broad, elliptical, pointed at both ends, veined, minutely serrated, with the lower serratures and petioles glandular, and are of a bright green color. The flowers are large, of a pale red color varying to white, with very short peduncles, and petals longer than the calyx, and usually stand in pairs upon the branches. The fruit is of the peach kind, with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, containing the kernel or almond.

There are several varieties of this species of *Amygdalus*, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The two most important are *Amygdalus (communis) dulcis* and *Amygdalus (communis) amara*, the former bearing sweet, the latter bitter almonds. Another variety is the *A. fragilis* of De Candolle, which yields the *paper-shelled almonds*. The almond tree is a native of Persia, Syria, and Barbary, and is extensively cultivated in the south of Europe. It has been introduced into the United States; but in the northern and middle sections the fruit does not come to perfection.

Bitter Almonds.—These are smaller than the sweet almonds, and are thus described in the U. S. Pharmacopœia. "Ovate or oblong-lanceolate, 20 to 30 Mm. long; seed-coat thin, brown, finely downy; embryo straight, white, and with two plano-convex cotyledons; taste bitter and oily; when triturated with water Bitter Almond yields a milk-white emulsion which emits an odor of hydrocyanic acid." U. S. They have the bitter taste of the peach kernel, and, though when dry, inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain nearly the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they also contained hydrocyanic acid and volatile oil, to which their peculiar taste and odor and their peculiar operation upon the system were ascribed. It was, however, ascertained by Robiquet and Boutron that these principles do not pre-exist in the almond, but result from the reaction of water; and Wöhler and Liebig proved, what was suspected by Robiquet, that they are formed out of a peculiar substance denominated *amygdalin*, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron in 1830, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. It is decomposed by the action of diluted acids or in the

presence of water by the nitrogenous ferments, like *emulsin*, which accompany it in the bitter almond. The reaction is as follows:

Crystallized
amygdalin.

Dextro-
glucose.

Hydrocyanic
acid.

Oil of bitter
almond.

It is recognized as belonging to the glucoside class, compounds which, when decomposed by diluted acids, alkalies, or ferments, yield glucose and some other characteristic decomposition product. They may be considered as esters of glucose analogous to the esters of glycerin which exist in the fats under the name of *glycerides*. Liebig and Wöhler give the following process for obtaining amygdalin, in which the object of the fermentation is to destroy the sugar with which it is associated. Bitter almonds, previously deprived of their fixed oil by pressure, are to be boiled in successive portions of alcohol till exhausted. From the liquors thus obtained all the alcohol is to be drawn off by distillation, care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is to be filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connection with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposit it upon cooling. If pure, it will form a perfectly transparent solution with water. Any oil which it may contain may be separated by washing with ether. One pound of almonds yields at least 120 grains of amygdalin. (*Ann. Pharm.*, xxii. 329.) Amygdalin appears to be extensively diffused in plants, having been noticed not only in the different genera of the *Rosaceæ*, as *Amygdalus*, *Cerasus*, and *Prunus*, but also by Wicke in various *Pomaceæ*, as *Pyrus Malus*, *Sorbus Aucuparia*, *Sorbus hybrida*, *Sorbus torminalis*, *Amelanchier vulgaris*, *Cotoneaster vulgaris*, and *Crataegus Oxyacantha*. (*Ann. Ch. Ph.*, lxxix. 79.) It may be advantageously procured from peach kernels, which have been found to yield 80 grains for each avoirdupois pound, or more than 1 per cent. (*A. J. P.*, xxvii. 227.) According to the researches of Johanne, the emulsin is contained in the radicle and plumule, and in the vascular bundles of the cotyledons, while the parenchyma of the cotyledons contains the amygdalin. (*P. J.*, March, 1888.)

Amygdalin, mixed with emulsion of sweet almonds, gives rise, among other products, to the volatile oil of bitter almond and hydrocyanic acid,—the emulsin in the sweet almonds acting the part of a ferment, by causing a reaction between the amygdalin and water; and the same result is obtained when pure *emulsin* is added to a solution of amygdalin. It appears, then, that the volatile oil and hydrocyanic acid developed in bitter almonds when

moistened result from the mutual reaction of amygdalin, water, and emulsin. Certain substances have the effect of preventing this reaction, as, for example, alcohol and acetic acid. It is asserted that emulsin procured from other seeds, as those of the poppy, hemp, and mustard, is capable of producing the same reaction between water and amygdalin, though in a less degree. (*Ann. Pharm.*, xxviii. 290.) Amygdalin appears not to be poisonous when taken pure in the stomach, unless there be emulsin in the food in the stomach.

Bitter almonds yield their fixed oil by pressure, and at the present time this oil is an article of commerce, and is frequently sold as oil of sweet almond, being produced from North African bitter almonds; the volatile oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. (*See Oleum Amygdalæ Amarae.*)

Uses.—Confectioners employ bitter almonds for communicating flavor to orgeat syrup. (*See Syrupus Amygdalæ.*) The kernel of the peach possesses similar properties, and is frequently used as a substitute. It has been ascertained that bitter almond paste, and other substances which yield the same volatile oil, such as bruised cherry-laurel leaves, peach leaves, etc., have the property of destroying the odor of musk, camphor, most of the volatile oils, creosote, cod liver oil, the balsams, etc.; and Mahier, a French pharmacist, has employed them successfully to free mortars and bottles from the odor of asafetida and other substances of disagreeable odor. All that is necessary is first to remove any oily substance by means of an alkali, and then to apply the paste or bruised leaves. (*See Amygdala Dulcis.*)

AMYGDALA DULCIS. U. S., Br.

SWEET ALMOND

(ä-mÿg'dä-lä dü'l'cis)

"The ripe seed of *Prunus Amygdalus* Stokes, var. *dulcis* De Candolle (Fam. *Rosaceæ*)." U. S. "The ripe seed of *Prunus Amygdalus*, Stokes, var. *dulcis*, Baillon. It is known in commerce as the Jordan almond." Br.

Semen Amygdali Dulce; Amandes douces, Fr. *Cod.*; Amygdalæ Dulces, P. G.; Süsse Mandeln, G.; Mandorle dolci, It.; Almendra dulce, Sp.

We are supplied with sweet almonds chiefly from Spain, the south of France, and Southern California. They are separated into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the *Jordan* and *Valencia* almonds, the former imported from Malaga, the latter from Valencia. The former are longer, narrower, more pointed, and more highly esteemed than the latter. The bitter almonds are obtained chiefly from Morocco, and are exported from Mogador.

Properties.—The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. Deprived of this covering, they are called *blanched almonds*. On exposure to the air they are apt to become rancid; but, if thoroughly dried and kept in well-closed glass vessels, they may be preserved unaltered for many years. The two varieties require separate notice.

Sweet almonds, when blanched, are without odor, and have a sweet, very pleasant taste, which has rendered them a favorite article of diet in all countries where they are readily attainable. They are, however, generally considered difficult of digestion. The U. S. Pharmacopœia thus describes them. "Closely resembling the Bitter Almond (see *Amygdala Amara*), but usually broader, with lighter seed-coat, having a bland, sweetish taste and giving no odor of hydrocyanic acid when triturated with water." *U. S.* By the analysis of Boullay, it appears that they contain, in 100 parts, 5 parts of pellicle, 54 of fixed oil, 24 of albumen, 6 of uncrystallizable sugar, 3 of gum, 4 of fibrous matter, 3.5 of water, and 0.5 of acetic acid, comprising loss. The albumen is somewhat peculiar, and is called *emulsin*. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a siphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution has an acid reaction, and, if heated to 100° C. (212° F.), becomes opaque and milky, and gradually deposits a snow-white precipitate, amounting to about 10 per cent. of the emulsin employed. (*A. J. P.*, xxi. 354.) Its distinguishing characteristic is that of producing certain changes noticed previously in amygdalin, which property it loses when its solution is boiled, though not by exposure in the solid state to a heat of 100° C. (212° F.). (*Ibid.*, 357.) It consists of nitrogen, carbon, hydrogen, and oxygen, with a minute proportion of sulphur, and is probably identical with the *synaptase* of Robiquet. L. Portes announced the discovery of *asparagin* in sweet almonds. (*N. R.*, January, 1877.) The fixed oil is described under the head of *Oleum Amygdalæ*, to which the reader is referred. Sweet almonds, when rubbed with water, form a milky emulsion, free from the odor of hydrocyanic acid, the insoluble matters being suspended by the agency of the albuminous, mucilaginous, and saccharine principles.

Uses.—*Sweet almonds* have no other influence on the system than that of a nutrient and demulcent. The emulsion formed by triturat-

ing them with water is a pleasant vehicle. From their nutritive properties, and the absence of starch in their composition, they are much used in the diet of *diabetics*, as originally recommended by Pavy. (*Guy's Hosp. Rep.*, 1862, p. 213.) *Bitter almonds* are more active, on account of the hydrocyanic acid developed in them. Largely taken, they have sometimes proved poisonous. Landerer mentions the case of a lady who was alarmingly affected by a bath made from the residue of bitter almonds after expression of the fixed oil (*A. J. P.*, xxviii.) Wöhler and Liebig propose as a substitute for cherry-laurel water, which owes its effects to the hydrocyanic acid it contains, but is objectionable from its unequal strength, an extemporaneous mixture of seventeen grains of amygdalin and one fluidounce of an emulsion made with two drachms of sweet almonds and a sufficient quantity of water. This mixture contains, according to the above-named chemists, one grain of anhydrous hydrocyanic acid, and is equivalent to two fluidounces of fresh cherry-laurel water. If found to answer in practice, it will have the advantage of certainty in relation to the dose, as amygdalin may be kept any length of time unaltered. If the calculation of Wöhler and Liebig be correct as to the quantity of acid it contains, not more than half a fluidrachm (1.8 Cc.) should be given as a commencing dose.

AMYLIS NITRIS. *U. S.* (Br.)

AMYL NITRITE [*Amyl Nitris*, *Pharm.* 1890]

(äm'y-lis nī'trīs)

$C_5H_{11}NO_2 = 116.24$

"A liquid containing about 80 percent. of Amyl (chiefly Iso-amyl) Nitrite [$C_5H_{11}NO_2 = 116.24$], when assayed by the process given below. It should be kept in hermetically sealed glass bulbs, or in dark amber-colored, glass-stoppered vials, in a cool and dark place." *U. S.* "A liquid produced by the interaction of amylie alcohol which has been distilled between 262° and 270° F. (127.7° to 132.2° C.) and nitrous acid. It consists chiefly of iso-amyl nitrite, $C_5H_{11}NO_2$, but contains also other nitrites of the homologous series." *Br.*

Amyl Nitris, *Br.*, Amylo-nitrosus Ether, Amylæther Nitrosus; Ether amylnitreux, *Fr. Cod.*; Ether amylozoteux, Azotite d'Amyl, *Fr.*; Amylum Nitrosum, *P. G.*; Amylnitrit, *G.*; Etere isoamylnitroso, *It.*; Nitrito de amilo, *Sp.*

This substance, which was discovered by Balard in 1844, should not be confounded with *amyl nitrate*, $C_5H_{11}NO_3$, which is not used as a medicine.

Preparation.—Amyl nitrite may be prepared by passing a stream of nitrous acid (hyponitric acid) gas through purified amyl alcohol at a temperature of 132° C. (269.6° F.), or by acting upon amyl alcohol with nitric acid, as

originally suggested by Balard. The alcohol should always first be purified according to the method of Hirsch (*A. J. P.*, 1862, pp. 139, 328), by agitating with an equal bulk of strong solution of common salt, then distilling in a retort with a thermometer, collecting what comes over between 125° C. (257° F.) and 140° C. (284° F.), and redistilling this until it has a boiling point near 132° C. (269.6° F.). The purified alcohol should be mixed with about an equal bulk of nitric acid in a capacious glass retort, being gradually heated until it approaches boiling, when the fire is to be removed. As soon as a thermometer inserted into the tubulures rises above 100° C. (212° F.) the receiver is changed, because both ethyl-amyl ether and amyl nitrate at such temperatures come over freely and would contaminate the product. The distillate obtained below 100° C. (212° F.) is agitated with a solution of potassium carbonate, and the oily liquid which separates is very slowly heated in a clean retort to 96° C. (204.8° F.), then the receiver is changed and the distillate collected as before, until the thermometer reaches 100° C. (212° F.). That which comes over between the two temperatures is pure amyl nitrite. It is essential to this process that in every case the heating be very gradual. (*A. J. P.*, 1871, p. 148.) Allen states (*Com. Org. Anal.*, 2d ed., i. 159) that the use of nitric acid is certain to result in the formation of much valeric aldehyde and more or less amyl nitrate, and the boiling point of the former of these bodies precludes the possibility of subsequently separating it by fractioning the crude product. He therefore prefers the passing of nitrous acid gas into purified amyl alcohol. John M. Maisch attempted to produce amyl nitrite by Redwood's process (*A. J. P.*, 1867, p. 330) for the production of nitrous ether, substituting amyl for ethyl alcohol. He found that the reactions occurred with such excessive violence as to render the preparation of the nitrite in this way impracticable. Subsequently, however, Alfred Tanner pointed out (*P. J.*, Nov. 1871, also *A. J. P.*, 1872, p. 21) that Maisch used a nearly anhydrous amyl alcohol, and that the reactions are equally violent with ethyl alcohol of similar strength. He finds no difficulty when the fusel oil is diluted with water, and prefers the process, especially for the production of the drug upon a small scale. Having introduced the purified amyl alcohol into a tubulated retort containing copper wire, he adds one-tenth of its bulk of strong sulphuric acid, and then the same quantity of nitric acid, previously diluted with an equal bulk of water, and heats gently to 63° C. (145.4° F.). At this temperature the reaction commences, and goes on very manageably, until a bulk about equal to double the quantity of nitric acid collects in the receiver. The chemical movement now ceases, and the temperature, which has risen to near 100° C. (212° F.), begins to fall. More diluted nitric acid is added, and the process carried out as

before. These additions are repeated until the amyl alcohol is exhausted, which is known by the appearance of red fumes in the retort. The whole product is washed with caustic soda, to remove hydrocyanic and other acids, and rectified over potassium carbonate, to get rid of moisture. The portion which distils over between 95° C. (203° F.) and 100° C. (212° F.) is medicinally pure amyl nitrite. John Williams (*Year-Book of Pharmacy*, 1885) recommends the method of passing nitrous acid, obtained by acting upon lump arsenic trioxide with nitric acid, sp. gr. 1.350, into purified amyl alcohol until the latter has assumed a brownish-green color; the product is then washed and distilled fractionally; the distillate under 100° C. and 105° C. amounted to nearly 95 per cent. D. B. Dott (*P. J.*, Aug. 31, 1878) called attention to the difficulties in the way of fixing a standard boiling point for amyl nitrite, and W. H. Greene (*A. J. P.*, 1879, p. 65) shows that nitropentane (an isomer of amyl nitrite) is almost invariably a constituent of amyl nitrite, and he believes that commercial amyl nitrite is frequently put upon the market unrectified, specimens examined having boiling points varying from 70° C. (155° F.) to 180° C. (356° F.).

Dunstan and W. Lloyd Williams (*P. J.*, 1888, p. 487) have shown that the supposed pure amyl nitrite is a mixture of α -amyl nitrite and β -amyl nitrite, arising from the fact that the amyl alcohol used is always a mixture of α -amyl alcohol and β -amyl alcohol in varying proportions. They find the α -amyl nitrite to be optically inactive and to boil at 97° C., while the β -amyl nitrite has dextro-rotatory power and boils at about 94° C. Much of the commercial amyl nitrite also contains iso-butyl nitrite, boiling at 67° C. It is a question whether the physiological action of commercial amyl nitrite is really due to the amyl nitrite or to impurities, especially to the iso-butyl nitrite, but the experiments of Brunton and Bokenham (*P. J.*, xix. 490) indicated that the commercial, impure nitrite is stronger than either pure α - or β -amyl nitrite. According to Bals and Broglio, the *tertiary amyl nitrite* differs from amyl nitrite in not giving rise to toxic symptoms, and in being slightly hypnotic.

Properties.—"A clear, yellowish liquid, of a peculiar, ethereal, fruity odor, and a pungent, aromatic taste. Specific gravity: 0.865 to 0.875 at 25° C. (77° F.). Almost insoluble in water; miscible, in all proportions, with alcohol or ether. It is very volatile, even at a low temperature, and is inflammable, burning with a yellow, luminous and sooty flame. It boils at about 96° to 99° C. (204.8° to 210.2° F.). If 1 Cc. of normal potassium hydroxide V.S. and 10 Cc. of water be mixed in a test-tube with a drop of phenolphthalein T.S., then 5 Cc. of Amyl Nitrite added, and the tube inverted a few times, the red tint of the aqueous layer should still be perceptible (limit of *free acid*). A mixture of 1.5 Cc. of silver nitrate T.S. and

1.5 Cc. of alcohol with a few drops of ammonia water should not become brown or black if 1 Cc. of Amyl Nitrite be added and the mixture gently heated (absence of *aldehyde*). Amyl Nitrite should remain transparent, or nearly so, when exposed to the temperature of melting ice (absence of *water*)." U. S.

"Almost insoluble in *water*; soluble in *alcohol* (90 per cent.) in all proportions. If it be added drop by drop to fused *potassium hydroxide*, potassium iso-valerianate will be formed. Specific gravity 0.870 to 0.880. Submitted to distillation, about 70 per cent. passes over between 194° and 212° F. (90° and 100° C.), the bulb of the thermometer not dipping below the surface of the residual fluid. A mixture of 5 volumes with sufficient *alcohol* (90 per cent.) to form 100 volumes affords a liquid of which a portion tested in a nitrometer as described under 'Spiritus Ætheris Nitrosi' should yield not less than 6 times its bulk of nitric oxide gas. On shaking with an equal volume of *solution of potassium hydroxide* the aqueous portion should have only a pale yellow color (limit of *aldehyde*). A small quantity in a test-tube placed in melting ice remains transparent (absence of *water*). It deteriorates unless kept in well-stoppered bottles." Br. According to Carl E. Smith (*A. J. P.*, 1898, p. 273), the U. S. 1890 method of assay (Allen's) is not accurate, owing to the nitric oxide instantly changing to nitrogen tetroxide on contact with air, and this continuing to set free iodine in the solution of hydriodic acid, thus registering too high a result. He proposes using a solution of potassium chlorate, nitric acid, silver nitrate, ferric ammonium sulphate, and potassium sulphocyanate.

Assay.—"Transfer about 3 Cc. of Amyl Nitrite, which has been previously shaken with 0.5 Gm. of potassium bicarbonate and carefully decanted, to a tared 100 Cc. measuring flask, and weigh it accurately. Add sufficient alcohol to bring the volume to exactly 100 Cc. and mix thoroughly. Introduce into a nitrometer (see PART III, Gasometric Estimations) exactly 10 Cc. of the alcoholic solution, followed by 10 Cc. of potassium iodide T.S., and afterwards by 10 Cc. of normal sulphuric acid V.S. When the volume of gas has become constant (within 30 to 60 minutes), note the volume of gas collected. Multiply this volume in Cc., by 4.8, and divide the product by the original weight of the Amyl Nitrite. At the standard temperature and pressure, the quotient will represent the percentage of Amyl Nitrite in the liquid. The temperature correction is one-third of one percent. of the total percentage just found for each degree,—additive if the temperature is below 25° C. (77° F.), and subtractive if it is above 25° C. (77° F.). The barometric correction is four-thirtieths of one percent. for each millimeter; additive if it is above, and subtractive if it is below 760. When assayed according to the above method, it should yield not less than 80 percent. of Amyl Nitrite." U. S.

Uses.—When inhaled in doses of from five to ten drops, amyl nitrite produces in man violent flushing of the face, accompanied with a feeling as though the head would burst, and a very excessive action of the heart. Along with these symptoms, after a larger quantity, there is a sense of suffocation, and more or less marked muscular weakness. As no case of serious poisoning from amyl nitrite has occurred in man, for a further knowledge of its action we are dependent upon studies made on the lower animals. In dogs, rabbits, cats, etc., it induces effects similar to those occurring in man, followed, after toxic doses, by violently hurried, panting respiration, progressive loss of muscular power and of reflex activity, and finally death from failure of respiration, sensation and consciousness being preserved to the last. Although the frequency of the pulse may be increased, the force of the circulation is always diminished. This decrease of the arterial pressure is in a great measure due to a dilatation of the capillaries. The vasomotor palsy appears to be chiefly produced by a direct action upon the coats of the capillaries, but may in part be caused by an influence exerted upon the vasomotor centres. The cause of the acceleration of the pulse is a depressing action upon the inhibitory cardiac centres, and it is also probable that small quantities of the drug act as a primary stimulant to the cardiac muscle.

The diminution of voluntary movements and of reflex action is chiefly owing to a powerful depressing influence exerted upon the spinal centres, although the drug does act to some extent upon both motor nerve and muscle, lowering their functional activity. Upon the perceptive and conscious portions of the nervous system amyl nitrite has almost no influence, so that, as already stated, both consciousness and sensation are preserved in poisoning by it almost to the close. After toxic doses the animal temperature falls in a remarkable degree. Very small doses produce in man a slight ($\frac{1}{2}$ ° F.) temporary increase of the bodily heat, probably caused by the vascular dilatation. The vapors of amyl nitrite outside of the body have a very extraordinary power of checking oxidation, and the results of numerous experiments seem to show that, in the body, the drug lessens decidedly the chemical interchanges. This is largely due to the formation of a new compound methæmoglobin, which being a comparatively stable body is not an efficient carrier of oxygen, the alteration in the composition of the blood may be recognized by the chocolate-brown color of the latter, but more accurately by the use of a spectroscope. With the possible exception of the decrease of temperature, the general symptoms produced by the poison do not seem to be due to this lowered oxidation, but to a direct influence exerted upon the various tissues. Locally applied, amyl nitrite causes a progressive loss of power in every highly organized

tissue; this may end in a total cessation of function, but, even after this, recovery is possible, provided the poison be withdrawn sufficiently early.

The chief indication for the employment of amyl nitrite is to relax *spasm*, either of the vasomotor muscular fibres or of the voluntary or involuntary muscles. A disease, probably associated with vasomotor spasm, but whose pathology is not established, in which experience has demonstrated the extreme value of amyl nitrite, is *angina pectoris*. Immediate and great relief is nearly always afforded, whether the heart-pain is or is not connected with *organic cardiac disease*. So far as experience goes, the cautious use of the remedy is safe, even when there is severe organic cardiac disease. In these cases it should always be administered by inhalation. Experience has also justified the use of the drug in many spasmodic diseases. In *asthma* the relief is often immediate; in *convulsions* occurring after labor the nitrite affords quiet, but its employment is dangerous on account of its tendency to produce uterine relaxation and consequent flooding. In *spasmodic dysmenorrhœa* good may be expected from its use; in *tetanus* it will frequently temporarily arrest the spasm and aid other remedies in securing recovery; in *strychnine poisoning*, in *hysterical convulsions*, indeed, in almost any convulsive disorder, much is to be expected from its employment. The convulsive stage of the ordinary *epileptic paroxysm* is so short that the nitrite is usually not available; when however, there is a marked *epileptic* condition and the patient passes from one convulsion to another, the drug may be used with benefit. In those cases in which there is an aura of sufficient length, the epileptic attacks may be arrested if the patient carry in the pocket pearls of the nitrite or a tightly-corked homœopathic vial containing five to ten drops of the remedy, and, as soon as the aura commences, inhale the vapor.

Amyl nitrite is generally administered by inhalation, usually in doses of from three to five drops, although much larger quantities have been given without bad results. The rule is to commence with three drops on a handkerchief held close to the nose, and then gradually to increase *pro re nata*. The handkerchief should always be withdrawn so soon as the face flushes or the heart begins to become excited, as the effects always increase for some time, even if no more be inhaled. The best method, however, of administering the very volatile liquid is by the use of glass pearls,—small flask-shaped vessels containing two, five, or ten minims of the nitrite; these are crushed in a handkerchief or towel when wanted for inhalation, the thin and fragile glass causing no inconvenience. The drug may also be given by the mouth.

Dose, from three to five minims (0.2 to 0.3 Cc.), given on sugar or dissolved in alcohol.

AMYLUM. U. S., Br.

STARCH [Corn Starch]

(ām'y-lūm)

"The starch grains obtained from the fruit of *Zea Mays* Linné (Fam. *Gramineæ*)." U. S.
 "The starch procured from the grains of common wheat, *Triticum sativum*, Lam.; maize, *Zea Mays*, Linn.; and rice, *Oryza sativa*, Linn." Br.

Amylum Tritici, P. G.; Amylum Zeæ, Wheat Starch; Amidon, Fr. Cod.; Fécule de Froment de Blé, de Maïs, Fr.; Stärkmehl, Stärkes, Kraftmehl, Maisstärke, Weizenstärke, G.; Amido, It.; Amidon, Sp.

Starch is a proximate vegetable principle contained in most plants, and especially abundant in the various grains, such as wheat, rye, barley, oats, maize, etc.; in other seeds, as peas, beans, chestnuts, acorns, etc.; and in numerous rhizomes and tuberous roots, as those of the potato, the sweet potato, the arrow-root, etc. The starch is always in the form of grains, which are contained within the parenchymatous cells, and is procured by reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine fecula which it holds in suspension has subsided. This, when dried, is starch, more or less pure, according to the care taken in conducting the process. Electricity has been used to bleach starch and thus raise its commercial value. (*D. C.*, 1893, 203.) In the U. S. P. of 1880 the official starch was that derived from wheat, but in the revision of 1890 corn starch was substituted. The starch of European commerce is largely obtained from the potato, while in the United States corn starch is almost exclusively in use, wheat and rice starch coming next in importance. For a description of the differences, see page 144.

Starch is white, inodorous and tasteless, pulverulent, opaque, and, as found in commerce, is usually in columnar or irregular angular masses which are easily reduced to powder, which produces a peculiar sound when pressed between the fingers. Its specific gravity is 1.505 at 67° F. (Payen.) It is composed of minute microscopic granules, in starch from the same plant nearly uniform in size, more or less plainly striate, and having a distinct hilum. In the different species of plants the starch granules differ in their characteristic forms. When exposed to a moist air, it absorbs a considerable quantity of water, which may be driven off by a gentle heat. It is insoluble in alcohol, ether, and cold water, but unites with boiling water, which, on cooling, forms with it a soft semi-transparent paste or a gelatinous opaline solution according to the proportion of starch employed. The paste placed on folds of blotting-paper, renewed as they become wet, loses water, contracts, and assumes the appearance of horn. If the proportion of starch be very

small, the solution, after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Heating with glacial acetic acid to 100° C., or with glycerin to 190° C., will also make starch soluble. Corn starch is officially characterized as "in fine powder or irregular, angular white masses, consisting of somewhat spherical, but usually polygonal grains, about 0.010 to 0.025 Mm. in diameter, with a lenticular, circular, or triangular central fissure; inodorous and tasteless; insoluble in cold water or alcohol; forming a whitish jelly when boiled with water, which when cool gives a deep blue color with iodine T.S.; triturated with cold water, showing neither acid nor alkaline reaction with litmus paper; when completely incinerated, leaving not more than 1 percent. of ash. When freed from water by careful drying in a current of warm air, Starch should show not less than 95 percent. of hydrolyzable carbohydrate." *U. S.* At a temperature of 160° C. (320° F.) for air-dried starch, and 200° C. (392° F.) for starch previously dried at 100° C., it is changed into *dextrin* (*British gum*), and at 200° C. (392° F.) to 215° C. (419° F.) forms a transparent fused mass, which consists exclusively of dextrin (Payen); at 220° C. (428° F.) to 230° C. (446° F.) it undergoes further change and yields chiefly *pyrodextrin*, a brown, tasteless, and odorless compound, readily soluble in water, insoluble in alcohol and ether. (Gelis, *Ann. Ch. Phys.*, (3) lii. 388.)

Composition and Nature.—The formula of starch is generally taken as $C_6H_{10}O_5$, or a multiple of this. Musculus, in 1861, showed that by the action of diluted acids or of *diastase*, starch is resolved into *dextrin*, $C_{12}H_{20}O_{10}$, and *dextrose*, $C_6H_{12}O_6$, so that its formula, in simplest terms, would be $(C_6H_{10}O_5)_n$. Recent determinations of its molecular weight by Brown and Morris make it as high as $5(C_{12}H_{20}O_{10})_{20}$. Iodine forms with starch, whether in its original state or in solution, a blue compound; and the tincture of iodine is the most delicate test for its presence. The color varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine be in excess, it is blackish blue; if the starch, violet blue. A singular property of starch iodide is that its solution becomes colorless if heated to about 93.5° C. (200° F.), and afterwards recovers its blue color upon cooling. By boiling, the color is permanently lost, while Puchot states that certain nitrogenized organic bodies, as albumin, prevent the reaction of iodine on starch or destroy it. (*N. R.*, Nov. 1876.) Alkalies unite with starch, forming soluble compounds, which are decomposed by acids, the starch being pre-

cipitated. It is thrown down from its solution by lime water and baryta water, forming insoluble compounds with these earths. The solution of lead subacetate precipitates it in combination with the oxide of the metal. Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. By long boiling with diluted sulphuric, hydrochloric, or oxalic acid, it is converted into *dextrin*¹ and glucose or grape sugar. A similar conversion into dextrin and glucose is effected by means of *diastase*, which change can be represented as taking place in several stages:

Many observers claim to recognize the production of other intermediate substances, as *amylodextrin* (soluble starch), *erythrodextrin*, *achroodextrin*, *maltodextrin*, none of which reduce Fehling's solution, followed by *maltose*, which does reduce Fehling's solution. Strong hydrochloric and nitric acids dissolve starch; and the latter acid, by the aid of heat, converts it into oxalic and malic acids. By the action of strong nitric, sulphuric, or crystallizable acetic acid, used with certain precautions, the starch is rendered soluble, and may be obtained in this state by separating the acid by means of alcohol. By the continued action of concentrated sulphuric acid it is decomposed. When it is dissolved in strong nitric acid, and precipitated by water, a white powder is thrown down, called *xyloidin*, $C_6H_9(NO_2)O_5$ (Braconnot), in which one atom of the hydrogen of the starch is replaced by one group, NO_2 , furnished by the nitric acid. Mixed with hot water and exposed to a temperature of 27° C. (80° F.), it undergoes chemical changes, which result in the formation of several distinct principles,

¹ *Dextrin* is a substance resembling gum in appearance and properties, but differing from it in not affording mucic acid by the action of nitric acid. It is largely dissolved by water, hot or cold, and forms a mucilaginous solution from which it is precipitated by alcohol. Large quantities of dextrin are now made both here and abroad and employed for various purposes in the arts, under the name of *artificial gum*. It is found in the market usually in the form of a yellowish or brilliant white powder, and in small masses or fragments resembling natural gum. It is made by the action either of acids or of *diastase* on starch, or by heating starch slightly moistened with nitric acid to a temperature of from 100° to 140° C. For particulars as to the manufacture, see paper by Thomas, republished in *Musculus* (vol. xix. p. 284). Researches of Naegeli and Musculus seem to show that the change of starch into dextrin takes place in several phases, and they name the products *amylodextrin*, *erythrodextrin*, *achroodextrin* *a* and *β*. For a fuller account see Husemann, *Pflanzenstoffe*, 2d ed., 1882. Dextrin, according to Payen, is converted into glucose through the action of *diastase*; but the glucose impedes the action unless removed; as, however, during alcoholic fermentation the glucose is consumed, the influence of *diastase* is not retarded. Hence dextrin by conversion into sugar may contribute to the alcoholic product.

among which are sugar, a gummy substance (perhaps *dextrin*), and a soluble modification of starch. With yeast, starch undergoes the vinous fermentation, being, however, first converted into sugar. Mixed with cheese and chalk it is said to yield alcohol without the previous saccharine conversion. (Berthelot, *J. P. C.*, 3e sér., xxxii. 260.) All plants which contain chlorophyll have the power of using the chemical rays of sunlight in producing from inorganic compounds and elements a substance which is organic. There is first formed in the centre of the chlorophyll granule a minute speck, which is believed to be starch; this new starch granule is incapable of solution, but by conversion into sugar or dextrin is rendered soluble, and in this form is carried in the juices of the plant. One of two destinies there awaits it. It may be converted into the permanent compound cellulose which constitutes the woody tissue, or it may be reconverted to its original form and be deposited in some part of the plant. These stores of starch are usually accumulated for future growth, and are especially seen in plants which flower in the spring before the leaves are put forth, or which reproduce the species without seeding.

When the potato is planted, the starch is converted into a soluble form, passes into the growing "eye" or bud, and, as cellulose, forms the new shoot. The structure and nature of the starch granule has been the subject of much investigation and discussion. Its microscopic appearance supports, but of course does not prove, the original theory advanced by Schleiden, that it is composed of concentric layers of similar chemical composition, in which the outer layer has been the first formed while the inner layers have been successively deposited in its interior. The microscopic characters, however, are just as readily explained on the theory that the central layer was the first formed and that the peripheral layers have been deposited around the point of the hilum. This view, originally advanced by Fritzsche in 1834, has been widely supported by various observers. Other authorities have come to the conclusion that the starch grain grows as do ordinary vegetable cells, but the theory brought forward in 1880 by Schimper, that all starch grains develop within plastids *i.e.*, in protoplasmic masses or cells, and that in starch which is stored, the leucoplastids finally disappear, is the theory which has been of recent times most widely believed and is probably correct. In stating his views, Schimper further came to the conclusion that the outer portion of the grain is the part most recently produced. That there is a marked difference in the layers of the starch grains is shown by the varying effects of staining reagents, certain parts of the grains being much more affected by safranin and gentian-violet than others. It would further appear that though the starch layers each contain colloidal substances besides crystalloidal cellulose, the proportion of their

constituents varies so much that the alternate layers are different, one set being colloidal and others crystalloidal, in their general nature. For details see Kraemer, *Botan. Gaz.*, vol. 24, Nov. 1902; also *Proc. Am. Philosoph. Soc.*, vol. xli.

Varieties.—Starch, as obtained from different substances, is somewhat different in its characters. *Wheat starch*, when examined with a microscope, is found to consist of granules varying from about $\frac{1}{1000}$ of an inch in diameter to a mere point, the smaller being spheroidal, the larger rounded and flattened, with the hilum in the centre of the flattened surface, and surrounded by concentric rings, which often extend to the edge. The granules are mixed with loose integuments, resulting from the process of grinding. This variety of starch has a certain degree of hardness and adhesiveness, owing, according to Guibourt, to the escape of a portion of the interior substance of the broken granules, which attracts some moisture from the air, and, thus becoming glutinous, acts as a bond between those which remain unbroken. Another opinion attributes this peculiar consistency to the retention of a portion of the gluten of the wheat flour, which causes the granules to cohere. Under the name of *corn starch*, a variety of fecula obtained from the meal of maize or Indian corn is much used for nutritive purposes in the United States. It is now the official starch. The granules of maize starch are very small, with a diameter not exceeding, according to Payen, one-sixth of that of the potato, and little more than one-half of that of the wheat granules. They have a very distinct hilum but no evident concentric striæ. *Rice starch* has extremely minute granules, nearly uniform in size, polygonal, without evident hilum or striæ. *Potato starch* is employed in various forms, being prepared so as to imitate more costly amylaceous substances, such as arrow-root and sago. In its ordinary state it is more pulverulent than is wheat starch, has a somewhat glistening appearance, and may be distinguished, with the aid of the microscope, by the size of its granules, which are larger than those of any other known fecula except canna, or *tous les mois*. They are exceedingly diversified in size and shape, though their regular form is thought to be ovate. The characters of other kinds of fecula will be given under the heads of the several official substances of which they constitute the whole or a part. According to Chevallier, starch is sometimes adulterated with calcium carbonate and calcium sulphate; and the fraud is also practised of saturating it with moisture, of which it will absorb 12 per cent. without any obvious change.

Uses.—Starch is nutritive and demulcent, but in its ordinary form is seldom administered internally. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions and prevent excoriation. Dissolved in hot water and allowed to cool, it is often employed in enemata, either as a vehicle, or as a

demulcent application in irritated states of the rectum; this liquid may also be used as an antidote in iodine poisoning, and given freely in other cases where amylaceous or mucilaginous drinks are indicated.

DILL FRUIT

(a-nē'thī frūc'tūs)

"The dried fruit of *Peucedanum graveolens*, *Benth.* and *Hook.*" *Br.*

Garden Dill, Dilly, Anet; Aneth, *Fr. Cod.*; Fenouil puant, *Fr.*; Dill, *G.*; Eneldo, *Sp.*

Anethum graveolens, Willd., *Sp. Plant.* i. 1469; Woodv., *Med. Bot.* p. 125, t. 48.—Dill is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain, Portugal, and the south of France, and is found growing wild in various parts of Africa and Asia. It is cultivated in all the countries of Europe, and has been introduced into our gardens. For a paper by J. C. Umney describing the commercial varieties, see *Year Book of Pharmacy*, 1898, 374. The seeds, as the fruit is commonly called, are the only part used. They are usually rather more than a line in length, and less than a line in breadth, of an oval shape, thin, concave on one side, convex and striated on the other, of a brown color, and surrounded by a yellowish membranous expansion. The dorsally compressed mericarps are usually separate and freed from the pedicel; each of them is broadly oval, about one-sixth of an inch long, flat, and furnished with three sharply keeled dorsal ridges, besides two marginal thin membranous projections or wings. The vittæ, or oil-tubes, are six in number, two upon the face and one in each furrow between the ridges. The odor is strong and aromatic, but less agreeable than that of fennel seed; the taste, moderately warm and pungent. These properties depend on a volatile oil. (See *Oleum Anethi*.) The bruised seeds impart their virtues to alcohol and to boiling water.

Uses.—Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion.

Dose, of the fruit, from fifteen grains to a drachm (1 to 3.9 Gm.); of the oil, two or three minims (0.12 to 0.2 Cc.).

ANISUM. U. S. (Br.)

ANISE

(a-nī'sūm)

"The ripe fruit of *Pimpinella Anisum* Linné (Fam. *Umbellifera*), obtained from cultivated plants." *U. S.* "The dried ripe fruit of *Pimpinella Anisum*, Linn." *Br.*

Anisi Fructus, *Br.*; Fructus (Semen) Anisi, *s.* Anisi vulgaris; Aniseed, Anny, Aneys, Annyle; Anis, Anis vert, Graines d'Anis, *Fr.*; Fructus Anisi, *P. G.*; Anissame, Anis, *G.*; Anice, Anace, Semi d'Aniso, *It.*; Anis (Fruto de), Simiente de Anis, *Sp.*; Anison, *Ar.*

Pimpinella Anisum, Willd., *Sp. Plant.* i. 1473; *B. & T.* 122. *Anisum vulgare*, Moench. This is an annual plant, about a foot in height, with an erect, smooth and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, or undivided, linear. The flowers are white, and in terminal compound umbels, destitute of involucre.

The anise plant is a native of Egypt and the Levant, but has been introduced into Southern Europe and is cultivated in various parts of that continent. It is also cultivated occasionally in the gardens of this country. The fruit is abundantly produced in Malta and Spain; in Romagna, in Italy, whence it is largely exported through Leghorn; and in Central and Southern Russia. The Spanish is smaller than the German or French, and is usually preferred; the Russian fruit is very short. It is said also to be extensively cultivated in India and South America, although we are not aware that the product ever comes into American commerce.

It is one of the oldest aromatics, having been spoken of by Theophrastus and cultivated in the imperial German farms of Charlemagne. In 1305 Edward I. granted a patent giving the right to levy tolls upon it at the Bridge of London for the purpose of repairing the bridge.

Anise seeds (botanically, fruit) are about a line in length, oval, striated, somewhat downy, attached to their footstalks, and of a light greenish-brown color, with a shade of yellow. "Ovoid, laterally compressed, 4 to 5 Mm. long; carpels usually cohering and attached to a slender pedicel; grayish or greenish-gray to grayish-brown; each with a flat face and five light brown filiform ridges and about 16 oil-tubes; odor and taste agreeable and aromatic. No mouse-like odor should be developed when solution of potassium hydroxide is poured upon Anise (absence of *coniium*). The powder contains one-celled, straight or curved, non-secreting hairs, which vary from 0.025 to 0.100 Mm. in length." *U. S.* Their odor and taste, which depend upon a peculiar volatile oil existing in the seed envelopes, are imparted sparingly to boiling water, but freely to alcohol. (See *Oleum Anisi*.) The internal substance of the seed contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the

two. The seeds are sometimes adulterated with small fragments of an argillaceous earth which resembles them in color; and their aromatic qualities are occasionally impaired by a slight fermentation, which they are apt to undergo in the mass, when collected before maturity. When examined by the microscope, anise is seen to contain a very great but variable number of small oil-tubes,—from fifteen to thirty to each mericarp. The epidermis is supplied with short, simple hairs, easily detached in making a section.

A case of poisoning is on record from the accidental admixture of the fruits of *Conium maculatum*, which bear some resemblance to those of anise, but may be distinguished by their crenate or notched ridges and the absence of oil tubes; by their mericarps being smooth, grooved upon the face, and having crenate or notched ridges with wrinkles between them. The conium fruits are, moreover, broader in proportion to their length, and are generally separated into half fruits (or single mericarps), while those of anise are whole (double mericarps).

Star aniseed, the *Cardamomum Siberiense* or *Annis de Sibérie* of the seventeenth century and the *badiane* of the French writers, is the product of *Illicium verum*, Hook. f., Gaertn., and is fully described under the heading *Illicium*, PART II. They contain about 4 per cent. of a volatile oil very closely resembling that of anise. There are no known chemical differences between these oils, although dealers distinguish them by their odor and taste.

Ruschenberger, U. S. N., has shown that oil of anise has a remarkable power of deodorizing potassium sulphide; a drop of the oil having entirely deprived of offensive odor a drachm of lard with which five grains of the sulphide had been incorporated. (*Am. J. M. S.*, N. S., xlviii. 419.)

Uses.—Anise, a grateful aromatic carminative, may be used in flatulent *colic*, and as a corrigent of griping or unpleasant medicines.

Dose, twenty to thirty grains (1.3 to 2.0 Gm.); of the oil, which should always be preferred, five to ten minims (0.3 to 0.6 Cc.).

ANTHEMIS. U. S. (Br.)

ANTHEMIS [*Chamomile*, English *Chamomile*,
Roman *Chamomile*]

(än'thē-mīs)

"The dried flower-heads of *Anthemis nobilis* Linné (Fam. *Compositæ*), collected from cultivated plants." U. S. "The dried expanded flower-heads of *Anthemis nobilis*, Linn., collected from cultivated plants." Br.

Anthemidis Flores, Br.: Flores Chamomillæ Romanæ, P. G.; Roman Low Garden, White or English Chamomile, Chamomile Flowers, Camil, Camovyne, Whig-plant; Camomille Romaine, Fr.; Römische Kamille, G.; Camomilla Romana, Camomilla Ingleses, It.; Manzanilla (Flor de), Manzanilla Romana, Sp.

Several species of *Anthemis* have been employed in medicine. *A. nobilis*, which is the subject of the present article, is by far the most important. *A. Cotula*, L., or *mayweed*, was formerly recognized by the U. S. Pharmacopœia. *A. Pyrethrum*, which affords the peltitory root, is among the official plants. (See *Pyrethrum*.) *A. arvensis*, L. (*corn chamomile*), a native of Europe, naturalized in this country, bears flowers which have an acrid bitter taste and possess medicinal properties analogous though much inferior to those of common chamomile. They may be distinguished by their want of odor. *A. tinctoria*, L., is occasionally employed as a tonic and vermifuge in Europe. *Matricaria suaveolens* is said to yield the chamomile of the Indian bazaars.

Anthemis nobilis, Willd., *Sp. Plant.* iii. 2180; B. & T. 154. *Chamomilla nobilis*, Godr. This is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upward at their extremities. The leaves are bipinnate, the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disk, and white rays. The involucre is of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like paleæ. The ray florets are numerous, narrow and terminated with three small teeth. The whole herb has a peculiar fragrant odor, and a bitter aromatic taste.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of *Roman chamomile*. By cultivation the yellow disk florets are often converted into the white ray florets. Thus altered, the flowers are said to be *double*, while those which remain unchanged are called *single*; but, as the conversion may be more or less complete, it generally happens that with each of the varieties there are intermingled some flowers of the other kind, or in different stages of the change. The double flowers are generally preferred; though, as the sensible properties are found in the greatest degree in the disk, the single are the more powerful. It is rather, however, in aromatic flavor than in bitterness that the radial florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white color, and are less efficient. The flowers which are largest, most double, and whitest should be preferred. They are thus described officially. "Subglobular, 1.5 to 2 Cm. broad, consisting of an imbricated involucre and numerous white, strap-shaped, obscurely three-toothed ray florets, and usually a few tubular disk florets, inserted upon a chaffy, conical, solid receptacle; odor agreeable; taste strongly aromatic and bitter." U. S.

The seeds yield by expression a fixed oil, which is said to be applied in Europe to various economical uses.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The medicine, as found in commerce, consists chiefly of the double flowers, and is imported from Germany and England. From the former country the flowers of *Matricaria Chamomilla* are also occasionally imported, under the name of chamomile. (See *Matricaria*.) In Europe the flowers of *A. arvensis*, L., corn chamomile, are sometimes substituted for the official drug. In France corn chamomile flowers are sold in commerce indiscriminately with those of *Anthemis nobilis*, of *Chrysanthemum parthenium*, (L.), Pers. (*Pyrethrum parthenium*, Smith), or of *Anthemis parthenoides*, De Cand., (*Matricaria parthenoides*, Desf.). (J. P. C., Mai, 1859, p. 347.) For the peculiar character by which these two flowers may be distinguished from the chamomile, see *Pyrethrum parthenium* in PART II.

Properties.—Chamomile flowers, as usually found in commerce, are large, almost spherical, of a dull white color, a fragrant odor, and a warmish, bitter, aromatic taste. When fresh, their odor is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamamelum* (*χαμαί*, on the ground, and *μήλον*, an apple); and it is somewhat singular that the Spanish name *manzanilla* (a little apple) has a similar derivation. The flowers impart their odor and taste to water and alcohol, the former of which, at the boiling temperature, extracts only one-fourth of their weight. The investigations of several chemists made in 1878–1879, in Fittig's laboratory at Strassburg, have shown the oil of chamomile to contain the following constituents:—a fraction distilling at 147° to 148° C. (296° to 298° F.) consisting of *isobutylic esters* and hydrocarbons; *isobutyl angelicate* at 177° C. (350.5° F.); *isoamyl angelicate* at 200° to 201° C. (392° to 394° F.); *isoamyl tiglicate* at 204° to 205° C. (399° to 401° F.) (both of these esters answering to the formula $C_8H_{11}C_5H_7O_2$). In the residual portion, hexylic alcohol, $C_6H_{13}OH$, and an alcohol of the formula $C_{10}H_{18}O$ isomeric with camphor, to which the name of *anethol* has been given (See *Chem. Cb.*, 1903 (1) 1226), are met with, both probably occurring in the form of esters. By decomposing the angelicates and the tiginate with potassium hydroxide, *angelic acid*, $C_5H_8O_2$, and *tiglic acid* (or *methyl-crotonic*) isomeric with the former are obtained to the extent of about 30 or more per cent. of the crude oil. In the oil examined by Fittig, angelic acid prevailed; from another specimen E. Schmitt (1879) obtained but very little of it, tiglic acid prevailing. Naudin (*Bull. Soc. Chim.*, 1884, 41, 483) extracted also a solid paraffin, $C_{18}H_{38}$, to which the name of *anthe-*

mene was given; Klopp obtained another body, *antheserin* from chamomile. (P. J., 1903, 458.) Umney states that pure oil of chamomile has the sp. gr. 0.905 to 0.912 at 15° C. (P. J., 1895, p. 949). The oil from *Anthemis Cotula* closely resembles that from *A. nobilis*, see A. J. P., 1885, pp. 376, 381. E. Amerman (A. J. P., 1889, p. 69) obtained a wax which was nearly white, bitter, and crystalline, melting at about 130° C., and a crystalline substance distinctly acid and of a glucosidal nature. There was no evidence of the presence of an alkaloid.

Uses.—Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in large doses capable of acting as an emetic. In cold infusion it is often advantageously used in cases of *enfeebled digestion* in convalescence, of *general debility*, with languid appetite, which often attends convalescence from idiopathic fevers. The flowers are sometimes applied externally in the form of fomentation, in cases of irritation or inflammation of the abdominal viscera, and as a gentle incitant in flabby, ill-conditioned ulcers. The infusion is usually preferred. The decoction and extract cannot exert the full influence of the medicine, as the volatile oil is driven off.

Dose, of the powder as a tonic, from half a drachm to a drachm (2.0 to 3.9 Gm.) three or four times a day, or more frequently.

Off. Prep.—Extractum Anthemidis, Br.

ANTIMONII ET POTASSII TARTRAS.

U. S. (Br.)

ANTIMONY AND POTASSIUM TARTRATE
[Tartar Emetic; Tartarated Antimony]

(ăn'ti-mō'nī-ē t pō-tās'sī-ē tār'trās)

"It should contain not less than 99.5 percent. of pure Antimony and Potassium Tartrate $[2C_2H_2(OH)_2(COOK)COOSbO + H_2O]$." U. S. "Tartarated Antimony, $[K(SbO)C_4H_4O_6]_2$ H₂O, is prepared by setting aside a mixture of antimonious oxide and acid potassium tartrate, made into a paste with a little water, until combination has taken place, and then purifying by crystallization from water." Br.

Antimonium Tartaratum, Br.; Potassium antimonij tartrate, Antimonium Tartarizatum, Tartarized Antimony, Tartarated Antimony; Potassio-Tartrate of Antimony, Antimonij Potassio Tartras, Tartarus Emeticus, Stibio-Kali Tartaricum; Tartrate d'Antimoine et de Potasse, Fr.; Cod.: Emétique, Tarte stiblé, Pr.; Tartarus Stibiatus, P. G.; Brechweinstein, G.; Tartrato di antimonio e di potassio, It.; Tartrato antimonico potassico, Sp.

A process for Tartar Emetic not now being given in the U. S. Pharmacopœia, that of 1870 follows: "Take of Oxide of Antimony, in very fine powder, *two troyounces*; Bitartrate of Potassium, in very fine powder, *two troyounces and a half*; Distilled Water *eighteen fluidounces*. To the Water, heated to the boiling point in a glass vessel, add the powders,

previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stoppered bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U.S.* 1870. This compound is a normal tartrate. Tartaric acid is dibasic. In acid potassium tartrate (cream of tartar) one of the two hydrogen atoms is replaced by potassium, while the other is unreplaced; in neutral potassium tartrate (soluble tartar) both are replaced by potassium; in tartar emetic one is replaced by potassium, while the other is replaced by the group (SbO) antimonyl, which is an univalent group, exactly replacing one hydrogen atom.

In the preparation of tartar emetic the cream of tartar should not be in excess, as in that case it is apt to crystallize, upon cooling, with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. The hot filtration, directed in the *U. S. Pharmacopœia* of 1870, may be conveniently performed by a jacketed funnel filled with hot water. In all cases the salt should be obtained in well-defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.¹

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide used for preparing tartar emetic. The preference, however, was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmacist of Paris, after a careful comparison of the different processes, declared also in its favor; his process will be found in detail in the *U. S. D.*, 17th ed., p. 175.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; it is not material what plan is adopted, provided the crystals of the antimonial salt be carefully purified. Mohr prefers the use of a moist oxide, prepared by adding gradually an intimate mixture of one part, each, of antimony trisulphide and potassium nitrate to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass thus formed is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *J. P. C.*, 3e sér., iii. 327. Yuntz (*A. Pharm.*, 1887, p. 641) communicates the following process for *Antimony Tartrate* (SbO)O₂, C₄H₆. An excess of antimony oxide is boiled

with solution of tartaric acid, the clear solution evaporated to a syrupy consistence, allowed to cool, and the crystalline precipitate which forms washed with alcohol to free it from any excess of tartaric acid.

Properties.—It is in the form of "colorless, transparent crystals of the rhombic system, becoming opaque and white on exposure to air, or a white, granular powder; without odor, and having a sweet, afterwards disagreeable, metallic taste. Soluble in 15.5 parts of water at 25° C. (77° F.), and in 3 parts of boiling water, but insoluble in alcohol, which precipitates it from its aqueous solution in the form of a crystalline powder. When heated to 110° C. (230° F.), the salt loses its water of crystallization (2.71 percent.). When heated to redness, it chars, emits an odor resembling that of burning sugar, and leaves a blackened residue having an alkaline reaction. The aqueous solution of the salt possesses a slightly acid reaction, and yields with hydrochloric acid a white precipitate, soluble in an excess of the acid; but no precipitate occurs if tartaric acid has previously been added." *U. S.* Antimony and potassium tartrate was discovered in 1631 by Adrian de Mynsicht. When prepared from the oxychloride it crystallizes in tetrahedrons. As it occurs in commerce, it is often in the form of a white powder, resulting from the pulverization of the crystals. It is insoluble in alcohol, but dissolves in proof spirit or wine. (See *Vinum Antimonii*.) Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. If one-fifth of its bulk of alcohol be added to the water, this decomposition is prevented. It is incompatible with acids, alkalies and their carbonates, some of the earths and metals, calcium chloride, and lead acetate and subacetate. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, etc.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity.—"In a solution of Antimony and Potassium Tartrate, acidulated with hydrochloric acid, hydrogen sulphide T.S. produces an orange-red precipitate, which is soluble in ammonium sulphide T.S. and potassium hydroxide T.S. Antimony and Potassium Tartrate is precipitated from its aqueous solution by tannic acid T.S., and yields a white precipitate with solutions of the alkaline carbonates and hydroxides, soluble in excess of the latter. An aqueous solution of the salt (1 in 100), acidulated with acetic acid, should not be affected by the addition of a few drops of barium chloride T.S. (absence of *sulphate*), silver nitrate T.S. (*chloride*), ammonium oxalate T.S. (*calcium*), or potassium ferrocyanide T.S. (*iron*). If to the aqueous solution of the salt (1 in 20) just sufficient sodium hydroxide T.S. be added to redissolve the precipitate formed, and if to this solution an equal volume of freshly prepared hydrogen

¹ For still another method of preparing tartar emetic, which we omit from want of space, see *J. P. C.*, 4e sér., xi. 404.

sulphide T.S. be added, no coloration should be noticeable after standing in a warm place for half an hour when viewed by reflected light while held against a white surface (absence of *heavy metals*). On adding sodium carbonate T.S. to crushed crystals of the salt, effervescence should not occur (absence of *potassium bitartrate*). Two Gm. of Antimony and Potassium Tartrate, when dissolved in 5 Ce. of hydrochloric acid, should not respond to Bettendorff's Test for arsenic (see PART III, Test No. 16). If 1 Gm. of Antimony and Potassium Tartrate be dissolved in sufficient water to measure 100 Ce., then 33 Ce. (32.99 Ce.) of this solution should, after the addition of 20 Ce. of a cold saturated aqueous solution of sodium bicarbonate and a little starch T.S., require not less than 19.9 Ce. of tenth-normal iodine V.S. to produce a permanent blue color (each Ce. corresponding to 5 percent. of the pure salt). Titration should begin immediately after the addition of the sodium bicarbonate solution." *U. S.* "Each gramme dissolved in water with 2 or 3 grammes of sodium bicarbonate should discharge the color of not less than 60.2 nor more than 60.7 cubic centimetres of the volumetric solution of iodine quickly introduced from a burette. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, calcium, sodium, ammonium, chlorides, or sulphates. It should not effervesce with solution of sodium bicarbonate (absence of acid potassium tartrate). 1.66 grammes should dissolve slowly but without residue in 25 cubic centimetres of water at 60° F. (15.5° C.)." *Br.* Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrogen sulphide, will be covered with an orange-colored deposit of antimony trisulphide. Entire solubility in water is not a character belonging exclusively to the pure salt, for, according to Hennell, tartar emetic may contain 10 per cent. of uncombined cream of tartar and yet be wholly soluble in the proper proportion of water. Hennell's method of detecting uncombined bitartrate is to add a few drops of a solution of sodium carbonate to a boiling solution of the antimonial salt. If the precipitate formed be not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, calcium tartrate, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Calcium tartrate is derived from the cream of tartar, which often contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue color being immediately produced by potassium ferrocyanide, added after a little acetic acid. If the blue color be slowly produced, it may arise from reactions on the

iron of the ferrocyanide itself. If much iron be present the solution of the tartar emetic will be yellow instead of colorless. According to Sérullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native antimony trisulphide, which almost always contains this dangerous metal. Subsequently, however, Thos. Williams (*P. J.*, July, 1874, p. 63) examined a number of samples of various antimonial preparations and found them remarkably free from arsenic. Tartar emetic should always be bought by the apothecary in good crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white; but when it is yellowish white, iron is probably present. A. H. Jackson found some samples of commercial tartar emetic to contain from 40 to 70 per cent. of potassium sulphate. (*Year-Book of Pharmacy*, 1885, p. 459.) Tartar emetic loses water of crystallization on exposure to dry air and is sometimes two per cent. stronger than the official product on this account.

It has been already stated in general terms that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Hydrochloric and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of antimony trichloride or subsulphate, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of acid. When solution of potassium hydroxide is added to a concentrated solution, it produces at first no effect, and then a precipitate of trioxide, which is redissolved on the continued addition of the alkali. Lime water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed calcium and antimony tartrates. Potassium carbonate affects still weaker solutions, throwing down a white precipitate of trioxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure trioxide. To these reagents may be added infusion of galls, which, when fresh and strong, causes a dirty-yellowish-white precipitate of antimony tannate.

Uses.—When tartar emetic is given in minute doses (gr. $\frac{1}{4}$, or 0.005 Gm.) to a healthy man it produces only a slight lessening of the force of the pulse and a tendency to increased secretion from the skin. After somewhat larger amounts these symptoms are more pronounced, and have nausea added to them. If a grain be ingested, the nausea and vomiting will be severe and persistent, and accompanied by marked prostration, both of the circulation and of the

muscular strength. In the lower animals antimony causes symptoms similar to those which it produces in man. It has been experimentally proved that the fall of the arterial pressure is produced, at least in part, by a direct action upon the heart. The loss of muscular power, of reflex activity, and of sensibility is believed to be due to depression of the spinal centres, and the disturbance of respiration to a direct influence upon the nerve-centres which preside over that function. The purging and vomiting are connected with an effort at elimination, the poison escaping through the gastro-intestinal mucous membrane, as well as through the kidneys. After death from antimony, fatty degeneration of the liver, kidneys, and other organs has been found, indicating that the poison has a powerful influence upon nutrition. It is evident that in small doses tartar emetic is powerfully depressant to the circulation and stimulant to the secretion of the skin. At one time tartar emetic was very largely used in medicine; at present it is employed almost solely as a diaphoretic and expectorant, having been supplanted by other less dangerous remedies as a circulatory depressant. In the first stage of a *bronchitis* in a sthenic subject, it is often of great service. Its emetic action is very certain, powerful, prolonged, and accompanied with much depression. It is very badly borne by children. Tartar emetic is occasionally used as a counter-irritant in the form of an ointment or plaster, whose application produces sooner or later a burning sensation accompanied by a very painful pustular eruption with ulcerations.

Poisoning.—Symptoms of acute poisoning by the drug are an austere metallic taste, excessive nausea, copious vomiting, frequent cough, burning pain in the stomach, colic, frequent stools and tenesmus, fainting, small, contracted, and accelerated pulse, coldness of the skin, and even of the internal organs, difficult and irregular respiration, cutaneous anæsthesia, convulsive movements, very painful cramps in the legs, prostration, and death. Ten grains (0.65 Gm.) is the smallest dose reported to have proved fatal. In rare cases vomiting and purging do not take place, and when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial.

When given in repeated small doses, tartar emetic produces both in man and in the lower animals a chronic poisoning, in which the chief symptoms are nausea, vomiting, watery purging, often followed by constipation, failing circulation, and a general asthenia, deepening into death from exhaustion. After death from antimonial preparations, decided evidences of gastro-intestinal irritation are apt to be present, but they have been in some cases wanting. The blood is often markedly fluid. Intense venous congestion, especially of the lungs, is usually present, and in some cases pulmonary apoplexy,

atelectasis, or other structural lesion of the lungs has been found. A wide-spread fatty degeneration has been noted as constant in chronic poisoning in animals, and probably occurs also in man.

The treatment of tartar emetic poisoning consists, first, in washing out the stomach with a solution of tannic acid; second, in meeting the symptoms as they arise, especially by the use of opiates, which should be administered hypodermically and by rectal suppositories; external warmth, stimulants, etc., should be used *pro re nata*. In all cases of suspected poisoning, the vomit, the passages from the bowels, and especially the urine, should be saved. The metal has been found in all the tissues of the body, but in the experiments of B. W. Richardson it was most abundant in the liver.

In examining the contents of the stomach or intestines for tartar emetic, they should be digested in water acidulated with hydrochloric and tartaric acids. The former acid will serve to coagulate organic matter, the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, should be subjected to a stream of hydrogen sulphide, which, if tartar emetic be present, will throw down the orange-red antimony tersulphide, distinguished from arsenic tersulphide and all other precipitates by forming with hot hydrochloric acid a solution, from which (after boiling to expel traces of hydrogen sulphide) a white curdy precipitate of antimony oxychloride (powder of Algaroth) is thrown down upon the addition of water. Hydrogen sulphide is by far the most delicate test for tartar emetic.

The mode of extracting the antimony from the solid tissues, recommended by Orfila, is to carbonize the dried viscera with pure concentrated nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with hydrochloric acid, assisted with a little nitric acid, to filter the liquor, and introduce it into Marsh's apparatus. Hydrogen antimonide will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain as a black stain, distinguishable from the similar stain produced by arsenic by its slighter volatility, by its forming with hot hydrochloric acid a solution which affords a white precipitate of antimony oxychloride when added to water, by its insolubility in solution of bleaching powder or chlorinated soda, and by its solubility in solution of stannous chloride. (*See Arseni Trioxidum.*)

Reinsch's process is a good one for separating antimony from the tissues, and was first used for that purpose by Alfred Taylor of London. The tissues are boiled in hydrochloric acid, and a bright slip of copper is immersed in the hot solution. The metallic film deposited on the copper must be proved to be antimony. This is done by Odling by first boiling the coated copper in a solution of potassium permanganate, with a little excess of potassium hydroxide, for a few minutes, whereby the anti-

mony becomes oxidized and dissolved, and then passing hydrogen sulphide through the filtered and acidulated solution. The characteristic orange-red precipitate of antimony trisulphide is produced, which may be tested for antimony as above mentioned. H. H. Watson has simplified Odling's process by dispensing with the use of the potassium permanganate. He subjects the coated copper slip, in a tube, to a boiling very dilute solution of caustic potassium hydroxide, the metal being alternately drawn out of and immersed in the solution, by the aid of a copper wire, until the whole of the coating is oxidized and dissolved. The solution is then treated as directed by Odling. (*M. T. G.*, July, 1857, p. 613.) Hydrogen antimonide (evolved either by galvanic processes or from zinc and sulphuric acid), when passed over sulphur, is decomposed, slowly in diffused daylight, very rapidly in sunlight, antimony sulphide forming, with liberation of hydrogen sulphide. The orange-red sulphide can be freed from excess of sulphur by exhaustion with carbon disulphide. (*Jones, J. C. S.*, i. 1876.)

Dose, as a diaphoretic or expectorant, one-twelfth to one-sixth of a grain (0.005 to 0.01 Gm.); as an emetic, half a grain (0.032 Gm.).

ANTIMONII OXIDUM. Br.

ANTIMONIOUS OXIDE [Antimony Trioxide]

(ān-tī-mō'nī-i ōx'ī-dūm)

$\text{Sb}_2\text{O}_3 = 286.24$

"Antimonious Oxide, Sb_2O_3 , may be prepared by pouring solution of antimonious chloride into water, and decomposing the precipitated antimony oxychloride with sodium carbonate." *Br.*

Antimonious Oxide, Oxide of Antimony; Stibium Oxydatum, Oxydum Antimonicum s. Stibicum; Oxyde d'Antimoine, *Fr.*; Antimonoxyd, *G.*; Oxido de antimonio, *Sp.*

This compound is no longer official in the U. S. Pharmacopœia. The process of the U. S. P. 1870 was as follows: "Take of Sulphuret of Antimony, in very fine powder, *four troy-ounces*; Muriatic Acid *eighteen troy-ounces*; Nitric Acid *a troy-ounce and one hundred and twenty grains*; Water of Ammonia *a fluid-ounce and a half*; Water, Distilled Water, each, *a sufficient quantity*. Introduce the Sulphuret into a flask, of the capacity of two pints, and, having added the Muriatic Acid, digest, by means of a sand-bath, until effervescence ceases. Then, having removed the flask from the sand-bath, add the Nitric Acid gradually; and, when nitrous acid vapors cease to be given off, and the liquid has grown cold, add to it half a pint of Water, and filter. Pour the filtered liquid gradually into twelve pints of Water, constantly stirring, and allow the precipitate to subside. Decant the supernatant

liquid, and wash the precipitate twice by decantation, using, each time, eight pints of Water. Then transfer it to a muslin filter to drain, and, after the draining is completed, wash it with Water until the washings cease to have an acid reaction. Next introduce it into a suitable vessel, and subject it to the action of the Water of Ammonia for two hours; at the end of which time transfer it to a moistened muslin filter, and wash it with Distilled Water as long as the washings produce a precipitate with nitrate of silver. Lastly, dry the precipitate upon bibulous paper with the aid of a gentle heat." *U. S. 1870.*

When antimony trisulphide is digested with hydrochloric acid, a chemical reaction takes place as follows:

the hydrogen of the acid uniting with the sulphur of the antimonial, and escaping as hydrogen sulphide, while the chlorine and antimony combine to form antimony trichloride, which is held in solution. The effect of the nitric acid is supposed to be to render the oxide whiter, by decomposing any remaining hydrogen sulphide, and thus preventing it from contaminating the product. Though the result thus far is an aqueous solution of the trichloride, this cannot be diluted beyond a certain degree without decomposition. Hence, if largely diluted, as when poured into an excess of water, decomposition takes place, and a white powder is precipitated, formerly called *powder of Algaroth*, which is mainly an oxychloride. The decomposition of the powder, however, is not uniform, as it contains more trioxide the greater the proportion of water used in the decomposition. The pure oxychloride, SbOCl , is formed when the proportion of 4 molecules of water to 1 molecule of antimony chloride exists, but with a relatively larger proportion of water the average composition of the powder is $\text{Sb}_4\text{O}_5\text{Cl}_2$, which may be considered as made up of $(\text{SbOCl})_2 + \text{Sb}_2\text{O}_3$. The oxychloride is first washed with abundance of water to separate adhering hydrochloric acid, and then acted upon by an alkaline solution (ammonia or sodium carbonate) to decompose the oxychloride, with the effect of adding to the amount of teroxide; after which the teroxide requires only to be washed with water in order to render it pure. The last washing separates the ammonium or sodium chloride resulting from the decomposition of the oxychloride; and the water of this washing is tested by silver nitrate, until the presence of chlorine ceases to be indicated.

Properties.—Antimony trioxide is a heavy, grayish-white powder, permanent in the air, almost insoluble in water, insoluble in alcohol and nitric acid, readily soluble in hydrochloric or tartaric acid, or in boiling solution of potassium bitartrate. Heated in close vessels it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion, it forms a fibrous

crystalline mass, of pearl color. Heated in open vessels it suddenly becomes red hot, and, by the absorption of oxygen, changes into Sb_2O_3 (antimony antimonate), which differs from the trioxide in being insoluble in hydrochloric acid, less fusible, and not volatile. "On dropping its solution in hydrochloric acid into water, a white precipitate is produced, which is at once changed to orange by hydrogen sulphide test-solution. If 1 Gm. of the Oxide be dissolved with the aid of 5 Gm. of tartaric acid in a little water, and the solution diluted with water to the measure of 100 Cc., portions of this solution should not be affected by test-solutions of silver nitrate (absence of *chloride*), barium chloride (*sulphate*), or potassium ferrocyanide (*iron and other metals*). If a solution of the Oxide in hydrochloric acid be diluted with water, until it just begins to become permanently turbid, and then precipitated with hydrogen sulphide, this precipitate, when collected and thoroughly washed, should be completely soluble in ammonium sulphide test-solution (absence of *copper and lead*). If 1 Gm. of the Oxide be dissolved in hydrochloric acid, and to this solution 1 Cc. of stannous chloride test-solution (see List of Reagents, Bettendorf's Test for Arsenic, PART III) be added, no turbidity or coloration should ensue within one hour (limit of *arsenic*)." *U. S.* 1890. "If 0.5 gramme be dissolved in a hot solution of 1 gramme of Acid Potassium Tartrate and the solution then made alkaline with 3 grammes of sodium bicarbonate, the cooled liquid should discharge the color of 70 cubic centimetres of the volumetric solution of iodine. Antimonious Oxide should yield no characteristic reaction with the tests for lead, copper, arsenium, calcium, sodium, or potassium, only slight reactions with the tests for iron, and only the slightest reactions with the tests for chlorides or sulphates. It should dissolve entirely when boiled with an excess of Acid Potassium Tartrate." *Br.* It is frequently impure from the presence of the before-mentioned antimony antimonate, in which case it is not *entirely* soluble in hydrochloric acid. If it contain oxychloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by silver nitrate. When antimony antimonate is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in hydrochloric acid.

Uses.—This oxide, which must not be confounded with the powder of Algaroth, has the general therapeutic properties of the antimonials. Like antimonial powder, it is not uniform in its effects, and ought not to be used in practical medicine. The inequality of action is plausibly explained by the state of the stomach as to acidity, the presence of acids giving the medicine activity, and this explanation is confirmed by the experiments of Osburn of Dublin. As to the French Codex oxide,

prepared by boiling the oxychloride with a solution of potassium bicarbonate, the inequality is attributed by Durand of Caen, to the presence of more or less trichloride, which is separated with difficulty. Objecting to the Codex oxide, Durand proposes to prepare the trioxide by precipitating tartar emetic with ammonia in excess. Thus obtained it contains no trichloride, and does not cause vomiting. (*J. P. C.*, 3e sér., ii. 364.) It was introduced into the British Pharmacopœia as an ingredient in *Pulvis Antimonialis*.

Dose, of antimony trioxide, three grains (0.20 Gm.) every two or three hours, but the drug should not be employed as a medicine.

Off. Prep.—*Pulvis Antimonialis, Br.*

ANTIMONIUM.

ANTIMONY

(ān-tī-mō'nī-ŭm)

Sb = 119.3

Stibium, *Lat.*; Antimoine, *Fr.*; Antimon, Spiessglanz Metall, *G.*; Antimonia, *It.*; Antimonio, *Sp.*

Metallic antimony, sometimes called *regulus of antimony*, is not official in the British or United States Pharmacopœias; but, as it enters into the composition of a number of important pharmaceutical preparations, we have thought it proper to notice it under a distinct head.

Antimony exists in nature—1, uncombined, 2, as an oxide; 3, as antimonous sulphide (tersulphide), and 4, as an oxysulphide. It is found principally in France and Germany, but has been discovered also in the provinces of New Brunswick and Ontario, Canada, the latter locality yielding a large portion of that consumed in the United States.

Extraction.—All the antimony of commerce is extracted from the native sulphide. The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace, where it is subjected to a gentle heat, being constantly stirred with an iron rake. This process of roasting is known to be completed when the matter is brought to the state of a dull grayish-white powder called *antimony ash*. By this treatment the antimony is partly trioxidized, and partly converted into antimonous acid, while nearly all the sulphur is dissipated in the form of sulphurous acid gas; a portion of trisulphide, however, remains undecomposed. The matter is then mixed with charcoal impregnated with a concentrated solution of sodium carbonate, and the mixture heated in crucibles, in a melting-furnace. The charcoal reduces the antimony trioxide, while the alkali unites with the undecomposed trisulphide, and forms melted scoria, which cover the reduced metal and diminish its loss from volatilization. Antimony is more generally obtained by the reduction by iron of the native sulphide. The reduction of the antimony sulphide by iron takes

place at a red heat, but as iron sulphide needs a higher temperature for its fusion, and its specific gravity is not much less than that of the metallic antimony, the mass must be heated to a white heat to effect a perfect separation, and this occasions a loss of antimony. In order to avoid this, sodium sulphide is added in practice, which unites with the iron sulphide to form a more fusible and lighter slag of double sodium and iron sulphide. For 100 parts of antimony sulphide are taken 42 parts of iron, 10 parts of anhydrous sodium sulphate, and $2\frac{1}{2}$ to $3\frac{1}{2}$ parts of carbon.

The purest commercial antimony is not entirely free from foreign metals, chiefly iron, lead, and arsenic. Lefort purifies it for the purposes of pharmacy by gradually adding twenty-five parts of the metal, in fine powder, to fifty parts of nitric acid, by the action of which the antimony is precipitated as antimonious acid, while the foreign metals remain in solution. The precipitate is then thoroughly washed with water containing a hundredth part of nitric acid, drained completely, mixed with three or four parts of powdered sugar, and reduced to the metallic state by being heated to redness in a Hessian crucible. Antimony is imported into the United States in the form of antimony sulphide, as antimony regulus or metal, and most largely as "hard lead", or antimonial lead, obtained as a by-product in smelting lead or silver ores which contain a small percentage of antimony. Both native antimony and stibnite, or antimonous sulphide, are also brought from South Ham, Canada. The production of metallic antimony in the United States in 1902 was 3561 short tons, valued at \$634,506, and in 1903, 3128 tons, valued at \$548,433. The importations of ore and regulus (or metal) during the year 1903 were 2,714,617 lbs. and 4,694,309 lbs. respectively.

Properties.—The time of the discovery of antimony is not known, but Basil Valentine was the first to describe the method of obtaining it, in his work entitled "*Currus Triumphalis Antimonii*," published towards the end of the fifteenth century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, of a silver-white color when pure, but bluish white as it occurs in commerce. Its atomic weight is 119.3 (or according to some authorities, 122), symbol Sb, sp. gr. 6.7 and fusing point 425° C. (797° F.), or about a red heat. On cooling, after fusion, antimony assumes an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated, it burns with the emission of white vapors, consisting of tetroxide, formerly called *argentine flowers of antimony*. A small portion being fused and then thrown upon a flat surface divides into numerous globules, which burn rapidly as they move along. It forms three combinations with oxygen, *antimony trioxide* (antimonous oxide), Sb_2O_3 , *antimony tetroxide*, Sb_2O_4 (by some considered to be an antimonate of the radical

antimonyl, SbO.SbO_3), and *antimony pentoxide* (antimonic oxide), Sb_2O_5 . The first of these unites with water to form antimonous acid, the salts of which are called *antimonites*, the third unites with water to form antimonic acid, the salts of which are called *antimonates*. The trioxide was noticed under the head of *Antimonii Oxidum*. The tetroxide is a white powder, yellowish when hot, and difficultly soluble in acids. It forms when either of the other two oxides is strongly heated in air. *Antimony ash*, described above, is also an impure tetroxide. *Antimonic acid* is a lemon-colored powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of the acid by a heat not exceeding 315.5° C. (600° F.). When exposed to a red heat, it parts with oxygen, and is converted into the *antimony tetroxide* just described. This, though medicinally inert, frequently forms a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis*.)

The antimonial preparations are active in proportion to their solubility in the gastric juice. According to Mialhe, those antimonials which contain the hydrated tetroxide, or are easily converted into it, are most active. Hence metallic antimony in fine powder, and tartar emetic, act with energy. The tetroxide is much more active when prepared in the moist than in the dry way. According to Sérullas, all the antimonial preparations except tartar emetic and butter of antimony (or trichloride) contain a minute proportion of arsenic. Tartar emetic is an exception, because it separates entirely, in the act of crystallizing, from any minute portion of arsenic in the materials from which it is prepared, the poisonous metal being left behind in the mother water of the process.

ANTIMONIUM NIGRUM PURIFICATUM. Br.

ANTIMONIOUS SULPHIDE

(ān-tī-mō'ni-ūm nī'grūm pū-ri-fī-cā'tūm)

$\text{Sb}_2\text{S}_3 = 334.09$

"Native antimonious sulphide, Sb_2S_3 , from which siliceous matter has been removed by fusion, reduced to fine powder, and, if any salt of arsenium be present, purified by digesting with half its weight of solution of ammonia for several days, washing and drying." Br.

Antimonii Sulphidum Purificatum, U. S. 1890; Purified Antimony Sulphide; Purified Black Antimony; Sulfure d'Antimoine pur, Fr. Cod.; Gereinigtes Schwefelantimon, G.; Trisolfuro di antimonio depurato, It.

Purified antimony sulphide was dropped at the eighth revision of the U. S. Pharmacopœia. The process of the U. S. P. 1890 is as follows:

"Antimony Sulphide, one hundred grammes [or 3 ounces av., 231 grains]; Ammonia Water, fifty cubic centimeters [or 1 fluidounce, $5\frac{1}{2}$ fluidrachms]; Water, a sufficient quantity.

Reduce the Antimony Sulphide to a very fine powder. Separate the coarser particles by elutriation, and, when the finely-divided sulphide has been deposited, pour off the water, add the Ammonia Water, and macerate for five days in a well-closed vessel, agitating the mixture frequently. Then let the powder settle, pour off the Ammonia Water, and wash the residue by repeated affusion and decantation of Water. Finally dry the product by the aid of a gentle heat." *U. S.* 1890.

The test for arsenic is as follows. "If one grain be dissolved in hydrochloric acid, and the solution, slightly diluted, be gently warmed with a piece of bright copper foil, the copper being washed, dried, and heated in a dry, narrow test-tube, no crystalline sublimate (of arsenous hydride) should form on the upper cool part of the tube." *Br.* (1885).

These processes are intended to furnish a black antimony sulphide better fitted for the manufacture of the official preparations of antimony and for internal administration. Copper, a common impurity in the crude sulphide, is rendered soluble by the ammonia water, while the subsequent washing and decantation effectually remove all soluble impurities. (See *Antimonii Sulphidum*, PART II.)

Properties.—"A heavy, grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At a temperature below a red heat it fuses to a dark brown liquid." *U. S.* 1890.

Tests.—"If 1 Gm. of the Sulphide be digested, and finally boiled, with 10 Cc. of hydrochloric acid, it should dissolve without leaving more than 1 per cent. of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide test-solution. If 2 Gm. of the Sulphide be mixed and cautiously ignited, in a porcelain crucible, with 8 Gm. of pure sodium nitrate, and, after cooling, the fused mass be boiled with 25 Cc. of water, there will remain a residue which should be white or nearly so, and not yellowish nor brownish (absence of other metallic sulphides). On boiling the filtrate separated from the last-mentioned residue with a slight excess of nitric acid, until no more nitrous vapors are evolved, then dissolving in it 0.1 Gm. of silver nitrate, filtering again if necessary, and cautiously pouring a few drops of ammonia water on top, not more than a white cloud, but no red or reddish precipitate, should appear at the line of contact of the two liquids (absence of more than about 0.1 per cent. of arsenic)." *U. S.* 1890. "A grayish-black crystalline powder decomposed on boiling with *hydrochloric acid*, an almost clear solution being formed and

hydrogen sulphide escaping. The solution affords the reactions characteristic of antimony. It should not yield more than slight characteristic reactions with the tests for arsenium."

Br.

Uses.—This preparation is not used in medical practice.

Off. Prep.—Antimonium Sulphuratum, *Br.*

ANTIMONIUM SULPHURATUM. *Br.*

SULPHURATED ANTIMONY [*Kermes Mineral*]

(ân-tj-mō'ni-ŭm sŭl-phŭ-ră'tŭm)

"A mixture containing antimony sulphides and oxides, Sb_2S_3 , Sb_2O_3 , Sb_2S_5 , Sb_4O_6 , and sulphur." *Br.*

Antimonii Oxysulphuretum, *Lond.*; Antimonii Sulphuretum Aureum, *Ed.*; Precipitated Sulphide of Antimony; Sulphur Stiblatum Aurantiacum, Sulphur Auratum Antimonii; Golden Sulphuret of Antimony, Golden Sulphur; Soufre doré d'Antimoine, *Fr. Cod.*; Stibium Sulfuratum Aurantiacum, *P. G.*; Goldschwefel, Gefälltes Schwefelantimon, *G.*; Kermes minerale, *It.*; Quermes mineral, Oxisulfuro de antimonio hidratado, *Sp.*

Sulphurated antimony was not introduced into the *U. S. P.* 8th Rev.; the *U. S. Pharmacopœia* of 1890 added the synonym "*Kermes mineral*" to this preparation, intending that it should be used when "*Kermes*" was ordered in prescriptions. The process was as follows:

"Purified Antimony Sulphide, *one hundred grammes* [or 3 ounces av., 231 grains]; Solution of Soda, *twelve hundred cubic centimeters* [or 40 fluidounces, 4 fluidrachms, 37 minims]; Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity*. Mix the Purified Antimony Sulphide with the Solution of Soda and *three thousand cubic centimeters* [or about 6½ pints] of Distilled Water, and boil the mixture over a gentle fire for two hours, with frequent stirring, and occasionally adding Distilled Water so as to preserve the same volume. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate. Wash the precipitate with hot Distilled Water until the washings are at most but very slightly clouded by barium chloride test-solution; then dry the precipitate at a temperature not exceeding 25° C. (77° F.), and rub it to a fine powder. Keep the product in well-stoppered bottles, protected from light." *U. S.* 1890.

"Antimonious Sulphide, *10 ounces* (Imperial) or 200 grammes; Sublimed Sulphur, *10 ounces* (Imp.) or 200 grammes; Caustic Soda, of commerce, *5 ounces* (Imp.) or 100 grammes; Diluted Sulphuric Acid, Distilled Water, of each a sufficient quantity. Dissolve the caustic soda in *five pints* (Imp. meas.) or two thousand cubic centimetres of the Distilled Water; with this solution mix the Antimonious Sulphide and the Sublimed Sulphur; boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same

volume; then, while the whole is still hot, add *nine pints* (Imp. meas.) or three thousand six hundred cubic centimetres of boiling Distilled Water; strain the product through calico; before the strained liquid cools add to it by degrees the Diluted Sulphuric Acid till the latter is in slight excess; collect the precipitate on a calico filter; wash with Distilled Water till the washings are free from sulphates; dry at a temperature not exceeding 212° F. (100° C.).” *Br.*

There are three preparations containing antimony and sulphur,—viz., the *amorphous precipitated antimony sulphide*, Sb_2S_3 , which while orange-red in color corresponds to the black native sulphide; a reddish-brown mixture known as “*Kermes mineral*,” which contains both antimony sulphide and oxide, and has an average composition $2\text{Sb}_2\text{S}_3 + \text{Sb}_2\text{O}_3$;¹ and the *golden sulphide*, which is antimonious sulphide, Sb_2S_3 , and is obtained by decomposing sulphantimonates like *Schlippe's salt*, $\text{SbS}_4\text{Na}_3 + 9\text{H}_2\text{O}$, by the addition of a strong mineral acid.

The first of these may be obtained by dissolving the powdered native sulphide in potassium hydroxide solution with the aid of heat, and then adding to this solution, which contains the antimony combined as potassium antimonite and sulphantimonite, sulphuric acid, when a reddish precipitate is formed which dries to a reddish-brown powder.

The second may be obtained by boiling the native sulphide or the red amorphous sulphide just described with sodium carbonate, and then allowing the compound to settle out from the hot filtered liquid as it cools.

The third may be obtained by first forming a sulphantimonate by boiling finely-powdered antimony sulphide and sodium hydroxide with sulphur (or sodium carbonate and chalk instead of the sodium hydroxide), and then adding the solution of this to diluted hydrochloric or sulphuric acid, when yellow Sb_2S_5 separates, according to the reaction:

Ten parts of Schlippe's salt yield in theory 4.17 parts of antimony pentasulphide. The U. S. 1890 sulphurated antimony belonged to the first kind above mentioned, the British (1898) to the third variety. E. G. Eberhardt recommends the more direct preparation of sulphurated antimony by treating the native sulphide with hydrochloric acid and precipitating the solution with hydrogen sulphide. The objection that arsenic might be found in the product was met by an examination which showed that traces of arsenic present were not

more than when the then official process had been employed. (*A. J. P.*, 1886, p. 229.) The color of sulphurated antimony or *Kermes mineral* is influenced by porphyzation, with the admixture of a little sugar or gum; if hastily porphyzied, the mixture has a violet tint; if carefully and slowly, it has a russet color.

Properties of the Precipitated Antimony Sulphide. (*Sulphurated Antimony, Br.*)—“An amorphous, reddish-brown powder, becoming lighter in color on exposure to light, and having neither odor nor taste. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. When heated in a dry test-tube, it emits moisture and leaves a black residue. If 1 Gm. of Sulphurated Antimony be gently heated with 10 Cc. of hydrochloric acid, it should dissolve, with the exception of a slight residue, which, when washed and dried, should burn on the application of a flame with the characteristic odor of sulphur, leaving not more than a scanty ash. The acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which, after being washed and dried, should weigh not less than 85 per cent. of the original weight of the sulphide. The liquid filtered from this precipitate yields an orange-red precipitate with hydrogen sulphide test-solution. If 1 Gm. of Sulphurated Antimony be shaken with 20 Cc. of hot water, the filtrate should be neutral to test-paper, should not be rendered more than slightly opalescent by barium chloride test-solution (limit of *sulphate*), or silver nitrate test-solution (limit of *chloride*), and should not be affected by ammonium oxalate test-solution (absence of *calcium*). When tested for arsenic, as described under Purified Antimony Sulphide, it should afford no reaction beyond the limit prescribed for the latter.”
U. S. 1890. “A dull-red powder, readily dissolved by *solution of sodium hydroxide*, also by hot *hydrochloric acid* with the evolution of hydrogen sulphide and the separation of sulphur. 3 grammes moistened and warmed with successive portions of *nitric acid* until red fumes cease to be evolved, and then dried and heated to redness, should leave a white residue weighing about 2 grammes. Sulphurated Antimony should not yield more than the slightest characteristic reactions with the tests for arsenium.”
Br. Water in which this preparation has been boiled should not yield a white precipitate with ammonium oxalate. The non-action of this test shows the absence of lime. When pure, precipitated antimony sulphide is completely soluble in a hot solution of potassium hydroxide; but, as it is found in commerce, a white substance is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of trioxide is dissolved; but, according to H. Rose, this method of determining the proportion of the trioxide cannot be relied on. Exposed to heat it takes fire, and

¹ Kermes mineral of the U. S. P. 1870 differed somewhat from that of the U. S. P. 1890. The former process produced a powder of a purplish-brown color, the product of the latter was reddish-brown; both powders became lighter in color on exposure to air and light (see U. S. D., 18th ed., p. 186).

burns with a greenish-blue flame, giving off sulphurous acid, while the metal remains behind in the state of a grayish oxide.

John Moss asserted before the London Pharmaceutical Society that the British process always yields a dark reddish or reddish-brown powder, but that the Kermes mineral in English commerce is golden yellow or yellowish red, and must be prepared by some other method. He was confirmed by Redwood and Atfield, the latter explaining that the official Kermes contains antimony trisulphide, the commercial antimony pentasulphide.

Uses.—Precipitated antimony sulphide (*sulphurated antimony*) is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, and is very little used. In combination with calomel and guaiac (*Plummer's pill*), it was formerly employed in *secondary syphilis* and *cutaneous eruptions*. (See *Pilule Antimonii Compositæ*, U. S. P. 1890.) During its use the patient should abstain from acidulous drinks.

Golden sulphide acts like Kermes mineral, but is much weaker, and must be given in a larger dose.

Dose, as an alterative, from one to two grains (0.065 to 0.13 Gm.), given twice a day, in the form of pill; as an emetic, from five to twenty grains (0.32 to 1.3 Gm.).

Off. Prep.—*Pilula Hydrargyri Subchloridi Composita*, Br.

ANTIPYRINA. U. S. (Br.)

ANTIPYRINE

(ān-tī-py-rī'nā)

$C_{11}H_{12}N_2O = 186.75$

"Phenyldimethylpyrazolon [$C_6HN_2O(CH_3)_2$, C_6H_5], obtained by the condensation of phenylhydrazine with aceto-acetic ether, and methylation of the product." U. S. "Phenazone, or phenyl-dimethyl-iso-pyrazolone, is obtainable from phenyl-hydrazine by interaction with aceto-acetic ether, and the subsequent interaction of the resulting phenyl-methyl-iso-pyrazolone with methyl iodide. Its constitution is indicated by the following formula:

Phenazonum, Br.; Phenazone; Phenyldimethylisopyrazolone, Methozine, Dehydrodimethylphenylpyrazine; Analgésine, Fr. Cod.; Antipyrine, Parodyne, Anodynine, Fr.; Pyrazolonum phenyldimethylicum, P. G.; Phenyldimethylpyrazolon, Antipyrin, G.; Antipyrina, It., Sp.

Antipyrine was made official for the first time in the U. S. P. 8th Rev., the patent having expired; the British Pharm. (Additions 1885) introduced it under the specially coined word "Phenazone."

Preparation.—Antipyrine has been prepared by other synthetic methods, such as acting with methylphenylhydrazine upon aceto-acetic ether, thus avoiding the separate methylating step, but the original process of Knorr, mentioned in the definition, has proved to be the best.

This compound is one of the first important synthetical remedies introduced into medicine; it is now generally conceded to be a derivative of pyrrol, C_4H_5N , a base found in coal tar

and in bone oil. From this base, $\begin{array}{c} HC=CH \\ | \\ HC=CH \end{array} >NH$,

pyrazole, $\begin{array}{c} HC=N \\ | \\ HC=CH \end{array} >NH$, is derived (see PART

II); from this pyrazolon, $\begin{array}{c} HC=N \\ | \\ H_2C-CO \end{array} >NH$, which

by molecular rearrangement yields isopyrazolon, $CH-NH$

$\parallel >NH$. Phenyldimethylisopyrazolon, $CH-CO$

$(CH_3)C-N(CH_3) >N(C_6H_5)$, is a substitution

product from this. Practically it is made by Knorr's patented process of acting upon phenylhydrazine, $C_6H_5-HN-NH_2$, with ethyl acetoacetate, $(CH_3.CO)CH_2.CO.C_2H_5$, when phenyl-

$(CH_3)C=N$ methyl-pyrazolon, $\begin{array}{c} | \\ H_2C-CO \end{array} >N(C_6H_5)$, is

formed. This is then methylated by treatment with methyl iodide, when the hydriodide of the finished base results. Another reaction's product—viz., that of a halogen butyrate upon phenylhydrazine and subsequent oxidation and methylation of the compound so obtained, which is also a phenyldimethylpyrazolon—is only an isomer of true antipyrine; not identical with it.

Properties.—It is officially described as "a colorless, almost odorless, crystalline powder or tabular crystals, with a slightly bitter taste. Soluble in less than 1 part of water, in 1 part of alcohol, 1 part of chloroform, and in 30 parts of ether at 25° C. (77° F.). When heated to 113° C. (235.4° F.) it melts. Upon ignition it is consumed without leaving a weighable residue. The aqueous solution has a neutral reaction upon litmus paper, but Antipyrine unites directly with acids to form salts. If to an aqueous solution of Antipyrine, tannic acid T.S. be added, an abundant white precipitate (tannate) is formed. If 0.1 Gm. of sodium nitrite and 12 Cc. of an aqueous solution of Antipyrine (1 in 100) be mixed, a nearly colorless liquid is obtained, which, upon the addition of 1 Cc. of diluted sulphuric acid, develops a deep green color (formation of *isonitroso-antipyrine*). If to 2 Cc. of a dilute aqueous solution of Antipyrine (1 in 1000) 1 drop of ferric chloride T.S. be added, a deep red color is produced, which upon the addition of 10 drops of sulphuric acid is changed to light yellow. Two

Ce. of an aqueous solution of Antipyrine (1 in 100) mixed with an equal volume of nitric acid assumes a yellowish color, passing to crimson on warming (distinction from *acetanilide* and *acetphenetidin*). On warming 0.1 Gm. of Antipyrine with sodium hydroxide T.S. and again warming after the addition of chloroform, the disagreeable odor of phenyl-isocyanide should not be developed (absence of *acetanilide*).” *U. S.* It is described in the British Pharmacopœia as “in colorless and inodorous scaly crystals with a bitter taste. Melting point about 235.4° F. (113° C.). Soluble in its own weight of water, in 1½ parts of alcohol (90 per cent.) or of chloroform, and in 40 parts of ether. 0.1 gramme of sodium nitrite and 12 cubic centimetres of a 1 per cent. aqueous solution of Phenazone yield a nearly colorless liquid which turns deep green on the addition of 1 cubic centimetre of diluted sulphuric acid. An aqueous solution of the same strength mixed with an equal volume of nitric acid assumes a yellow color, passing to crimson on warming. *Test solution of ferric chloride* produces in a very dilute aqueous solution a deep red color, which is nearly discharged by excess of diluted sulphuric acid. A 5 per cent. aqueous solution of Phenazone gives with *test-solution of mercuric chloride* a white precipitate which disappears on boiling, but reappears as the liquid cools. The aqueous solution should not affect *solution of litmus*, and should not be affected by *hydrogen sulphide*. 2 cubic centimetres of a 1 per cent. aqueous solution should be colored green by 2 drops of *fuming nitric acid*, and the color should be changed to red by boiling with an additional 3 or 4 drops of the acid.” *Br.*

Uses.—Antipyrine, when given in such doses as simply to produce physiological effects, causes languor, malaise, a peculiar livid complexion, and in many cases an eruption upon the skin very closely resembling measles. In some instances an erythema or a violent urticaria or even wide-spread oedematous dermatitis is produced. When these skin symptoms are severe, the mucous membranes may share in the irritation, and a general rise of temperature, dyspnoea, hysterical unrest, and even more severe constitutional symptoms come on. The ordinary symptoms of poisoning by antipyrine are cephalic distress, giddiness, tremblings, excessive sweating, increased frequency of the pulse, often accompanied by precordial anguish, fall of temperature, arrested respiration, exaggeration of the reflexes, followed, if the dose has been large enough, by somnolence deepening into coma, and passing into profound stertorous unconsciousness, with dilatation of the pupil and epileptiform convulsions. In some cases of poisoning the chief symptoms have been those of profound progressive collapse. Various irregular symptoms have been noted, such as amaurosis, pseudo-membranous stomatitis, swelling of the lips and tongue, laryngeal interference with the respiration. When antipyrine is given in fever it acts as a very powerful

and certain antipyretic, the fall of temperature usually appearing in half an hour after the dose, and being very marked and continuing for some hours. It is usually, but not always, accompanied by a profuse sweat, which is not, however, the cause of the fall of temperature, as the latter may occur without the sweat, and is not prevented by hypodermic injections of atropine which check the perspiration. With the fall of temperature there is usually a decrease in the rate but not in the force of the pulse. Physiological doses of antipyrine have very little influence upon the circulation, and a reduction of temperature in febrile animals of four or five degrees with complete steadiness of the arterial pressure may be often observed. That the fall of temperature is not due to an action upon the circulation is further shown by the calorimetric experiments of Wood, Reichert, and Hare, which clearly demonstrate that there is an absolute decrease in the production of animal heat caused by the action of the drug upon the nervous system.

The work of physiologists has proved that antipyrine has a peculiar influence upon the cerebral cortex: that when in toxic dose it probably acts as a primary stimulant and a secondary depressant to the spinal cord; that it paralyzes both the motor and the sensory nerve-trunks, and has some distinct but feeble influence upon the muscles themselves; that in very large doses it increases the arterial pressure, although toxic doses decrease the pressure, probably in part by an action upon the vessels and in part by an action upon the heart; that upon the respiration antipyrine has no distinct influence, unless in toxic dose, when it seems to act as a primary stimulant and secondary depressant to the respiratory centres.

The absorption and elimination of antipyrine are rapid; it has been detected in the urine in less than half an hour after its ingestion. The chief channel of escape is the kidneys, but it has been detected in the milk of nursing women. It appears in health and in fever to diminish the elimination of urinary solids, and the whole output from the body of the nitrogenous products of tissue-waste. A peculiar livid discoloration of the surface of the body is one of the most characteristic symptoms of antipyrine poisoning, and is probably due to the formation in the blood of methæmoglobin or of some similar compound.

Antipyrine has been used in practical medicine to meet various indications. First, for the relief of pain. As an analgesic it is of no value when the pain is dependent upon a local inflammation, but it is often remarkably efficient in *migraine*, in the fulgurant pains or the pain-crises of *locomotor ataxia*, and in other paroxysms of suffering dependent upon disease of the nerve-centres or having the character of nerve-storms; it is also useful in the pains of *rheumatism* and of *neuritis*. Second, for the quieting of nervous irritation, as in nervous *urticaria*, *nocturnal emissions*, and

hysterical unrest. Third, for the purpose of combating excitability of the motor nerve-centres, as in *laryngismus stridulus*, *chorea*, *whooping cough*, *tetanus*, *epilepsy*. In the latter disease it usually fails, but sometimes acts with extraordinary power. The combination of it with ammonium bromide is much more efficacious in epilepsy than are the bromides by themselves. Fourth, to affect secretion, as in infantile *diarrhœa*, in *diabetes*, true and insipid, and as an antilactagogue when it is desired to arrest secretion of milk. Clément (*Lyon Méd.*, 1891) affirms that it is remarkably effectual in bringing about the absorption of pleuritic effusions. Fifth, as an antipyretic. For this purpose it has been employed in all diseases with high temperature, and, as it has little influence upon the circulation, may be used in asthenic fevers. Usually the fall of temperature which it produces is accompanied by marked increase in the comfort of the patient, but occasionally severe collapse occurs.

Locally, antipyrine is sometimes used for benumbing sensitiveness of the mucous membrane of the throat and nose, but its anæsthetic powers are not comparable with those of cocaine. It has also been employed as a hæmostatic, especially in *nasal hemorrhage*. For either of the above purposes a 15 to 50 per cent. solution may be employed.

Antipyrine has in a number of cases produced serious poisoning, and sometimes acts out of all proportion to the amount of the drug which has been exhibited. The hypodermic injections at times produce local irritation, but usually they are well borne. The full antipyretic dose for the adult should not exceed twenty grains (1.29 Gm.), repeated in half the quantity every half hour until forty grains have been taken or a fall of temperature or sweating occurs. The analgesic dose is from ten to fifteen grains (0.65 to 1.0 Gm.); in epilepsy ten grains (0.65 Gm.) a day may be continuously exhibited. Owing to the readiness with which antipyrine is decomposed, when prescribed with many other remedies in liquid form, it is preferably administered in the form of powder, pill or capsule.

Dose, five to twenty grains (0.32 to 1.3 Gm.).

APOCYNUM. U. S.

APOCYNUM [Canadian Hemp]

(a-pöc'y-nüm)

"The dried rhizome of *Apocynum cannabinum* Linné, or of closely allied species of *Apocynum* (Fam. *Apocynaceæ*)." U. S.

Black Indian Hemp; Dogsbane; Chanvre du Canada, *Fr.*; Canadische Hanfwurzel, *G.*

There are two indigenous species of this genus, *A. cannabinum*, L., and *A. androsæmifolium*, L., of very similar general aspect. Both plants abound in a milky juice, and have a

tough fibrous bark, which, by maceration, affords a substitute for hemp; hence the common name.

In the official species the stems and branches are upright or ascending, terminated by erect and close, many-flowered cymes, which are usually shorter than the leaves, and the corolla has nearly erect lobes, with the tube not longer than the lanceolate divisions of the calyx. In *A. androsæmifolium* the branches are divergently forked, the cymes loose and spreading, the open bell-shaped corolla with revolute lobes and a tube much longer than the ovate-pointed divisions of the calyx. The two plants grow together, although *A. cannabinum* seems to be proportionately more common in the West. *A. androsæmifolium* was formerly included in the U. S. secondary list, but is asserted to be inert. It is sometimes sold as true *Apocynum*, but its herbal parts are easily distinguished by their botanical characters; further, according to E. A. Manheimer, its root can be distinguished by the thick-walled bast-cells, which are arranged somewhat in a circle near the middle of the bark. (*A. J. P.*, Nov. 1881. See also *A. J. P.*, 1888.)

The root of *A. cannabinum* is five or six feet in length, about one-third of an inch thick, dividing near the end into branches which terminate abruptly, of a yellowish-brown color when young, but dark chestnut when old, of a strong odor, and a nauseous, somewhat acrid, permanently bitter taste. The internal ligneous portion is yellowish white and less bitter than the exterior or cortical part. "Of varying lengths, 3 to 8 Mm. thick, cylindrical or with a few angles produced by drying, lightly wrinkled longitudinally, and usually more or less fissured transversely; orange-brown, becoming gray-brown on keeping; brittle; fracture sharply transverse, exhibiting a thin brown layer of cork, the remainder of the bark nearly as thick as the radius of the wood, white or sometimes pinkish, starchy, containing laticiferous ducts; the wood yellowish, having several rings, finely radiate and very coarsely porous; almost inodorous, the taste starchy, afterwards becoming bitter and somewhat acrid." U. S. The fresh root, when wounded, emits a milky juice, which concretes into a substance resembling caoutchouc. In the dried state, it is brittle and readily pulverized, affording a powder like that of *ipeacacuanha*.

Schmiedeberg (*Pflanzenstoffe*, 2d ed., p. 1332) found two principles both of which acted like digitalin: one, an amorphous resinous substance, not a glucoside, easily soluble in alcohol and ether, almost insoluble in water, which he called *apocynin*, and the other, a glucoside, easily soluble in water, which he named *apocynëin*. Neither of the principles gives any color reaction with sulphuric acid and bromine. Merck & Co. offer for sale a crystalline principle, *apocynin*, which H. C. Wood, Jr., has shown to be almost inert, and not the active principle of *apocynum*. The fluid-

extract of apocynum yielded to H. C. Wood, Jr., a crystalline substance which he believes to be identical with Merck's apocynin, and an amorphous extremely active substance which he believed to be an impure glucoside. (*J. A. M. A.*, Dec. 24, 1904.) The root yields its virtues to water and alcohol, but, according to Griscom, more readily to the former. J. U. Lloyd noticed a white, tasteless, crystalline, waxy precipitate formed in a fluidextract of *A. cannabinum*. Von Oefele (*Journ. Pharm. Elsass-Lothr.*, 1891, 325) describes *apocysteine*, an alkaloid obtained from *A. venetum*; it is said to be a cardiac sedative.

Uses.—There is much clinical testimony to show that apocynum is a valuable cardiac stimulant and diuretic, useful especially in cases of *cardiac dropsy*, and also, it is stated, in *chronic Bright's Disease*. (See *T. G.*, 1898, 1899.) In very large doses it causes violent vomiting and sometimes purging, though we know of no serious cases of poisoning by it on record.

The physiological testimony in regard to its action is insufficient and discordant. According to D. A. Sokoloff, the administration of apocynum has the effect of producing a primary rise of the arterial pressure which is due to a stimulation of the heart, and the vasomotor centres, followed, if the dose has been sufficient, by fall of pressure caused by depression of the same parts. In the experiments of J. Rose Bradford, apocynum was found to lessen the frequency and increase the force of the cardiac beat, arresting in the frog the heart in systole and in mammals sometimes in diastole and sometimes in systole; but not producing increase in the blood pressure or acting upon the vasomotor centres. Peteruti and Somma state that the decoction of apocynum acts chiefly as an emeto-cathartic, increasing the rate of the heart beat. In their experiments the tincture was found to be free from gastro-intestinal irritant effects. The difference in the action of the two preparations is explained by the supposition that apocynin, being soluble in boiling water and insoluble in diluted alcohol, is present in the decoction but not in the tincture.

Commercial apocynin is an impure substance obtained by the precipitation of a strong tincture with water, and is said to be highly effective in doses ranging from one-sixth to one-third of a grain. It is stated that from fifteen to thirty grains (1 to 2 Gm.) of powdered apocynum root produce copious vomiting and purging. The decoction (half an ounce in one and a half pints boiled to a pint) may be given in doses of one to two fluidounces (30 to 60 Cc.) at short intervals. The dose of the aqueous extract is set down at three to four grains (0.2 to 0.26 Gm.) three times a day. The fluidextract is perhaps the best form of preparation.

Dose, of apocynum, five to fifteen grains (0.32 to 1.0 Gm.).

APOMORPHINE HYDROCHLORIDE

[Apomorphinæ Hydrochloras, Pharm. 1890,
Apomorphine Hydrochlorate]

(äp-q-mŏr-phĭ'næ hŷ-drŏ-ghlŏ'rĭ-dŭm)

$C_{17}H_{17}NO_2 \cdot HCl = 301.34$

"The hydrochloride [$HCl \cdot C_{17}H_{17}NO_2$] of an alkaloid prepared from morphine by the abstraction of one molecule of water. It should be kept in small, dark amber-colored vials, which have been previously rinsed with diluted hydrochloric acid and dried." *U. S.* "The hydrochloride, $C_{17}H_{17}NO_2 \cdot HCl$, of an alkaloid obtained by heating morphine hydrochloride or codeine hydrochloride in sealed tubes with hydrochloric acid." *Br.*

Hydrochlorate of Apomorphine; Chlorhydrate d'Apomorphine, *Fr. Cod.*; Apomorphinum Hydrochloricum, *P. G.*; Apomorphinhydrochlorid, *G.*; Cloridrato di apomorfina, *It.*; Cloruro de apomorfina, *Sp.*

Apomorphine was discovered by Matthiessen and C. A. Wright. It is prepared by heating morphine in a closed tube with a great excess of hydrochloric acid for two or three hours to the temperature of 140° to 150° C. The contents of the tube are then dissolved in water, an excess of sodium bicarbonate added, and the precipitate exhausted with ether or chloroform. On the addition to the solution of a very small quantity of hydrochloric acid, crystals of apomorphine hydrochloride form. The process is one of dehydration; the morphine parting with one molecule of water, the formula of apomorphine being $C_{17}H_{17}NO_2$. Apomorphine may also be made by the action of hydrochloric acid upon codeine, and it is affirmed that the best method in practice is that of E. Mayer, in which morphine is treated with a solution of zinc chloride, at 120° C. (*Ber. d. Chem. Ges.*, Berlin, 1871, iv, 121.) Codeine, $C_{18}H_{21}NO_3$, when treated with hydrochloric acid, yields first $C_{18}H_{20}ClNO_3$, and then splits off methyl chloride, CH_3Cl , and leaves apomorphine, $C_{17}H_{17}NO_2$. Pschorr (*Ber. d. Chem. Ges.*, 1902, 4377) believes that apomorphine is a derivative of phenanthrene-quinoline.

Properties.—Apomorphine Hydrochloride is officially described as in "minute grayish-white monoclinic prisms, glistening, odorless, having a slightly bitter taste, and acquiring a greenish tint upon exposure to light and air. Soluble in 39.5 parts of water, 38.2 parts of alcohol, 1864 parts of ether, and in 3800 parts of chloroform at 25° C. (77° F.); soluble in 16 parts of water at 80° C. (176° F.) and in 30 parts of alcohol at 60° C. (140° F.). The salt decomposes between 200° and 210° C. (392° and 410° F.), and melts at 263° C. (507° F.). The aqueous solution shows a neutral reaction with litmus paper. If the salt imparts at once an emerald-green color to 100 parts of water on

being shaken with it a few times in a test-tube, it should be rejected. Apomorphine Hydrochloride is not colored when treated with sulphuric acid; with nitric acid a deep purple color fading to orange is produced; with sulphuric acid containing a trace of selenous acid, a dark blue color, fading to violet, and then turning black; with sulphuric acid containing a trace of nitric acid, a blood-red color, fading to orange; with sulphuric acid containing a trace of ferric chloride, a pale blue color; with sulphuric acid containing a trace of ammonium vanadate, a violet-blue color, changing to deep greenish-blue; with sulphuric acid containing a little paraldehyde, a green color, fading to reddish-brown; with sulphuric acid containing potassium iodate, a black color, changing to brown, and finally to pale brown. If sulphuric acid be added to a crystal of Apomorphine Hydrochloride and a crystal of potassium nitrate, the latter is colored red, and on stirring with a glass rod the solution becomes green, then blue, then purple, and finally cherry-red. Acetic acid dissolves the salt without color, but on adding a trace of potassium iodate, the solution turns blood-red, changes to purple, and on adding a little ether and shaking, the latter assumes a blue color. Gold chloride T.S. produces a reddish-purple precipitate in a solution of the salt. Diluted ferric chloride T.S. colors Apomorphine Hydrochloride solution red (distinction from *morphine*, which, by the same test, is colored blue). Silver nitrate T.S. added to the aqueous solution of the salt throws down a white precipitate, insoluble in nitric acid, soon turning black by reduction to metallic silver, and instantly reduced by the addition of ammonia water. If 0.05 Gm. of the salt be shaken with a solution made by dissolving 0.05 Gm. of ferrous sulphate in 10 Cc. of water, the solution will gradually turn blue and then black; upon the addition of some alcohol the solution resumes its blue color (difference from *codeine*, *morphine*, *narceine*, and *narcotine*).” U. S.

“Small grayish-white, shining, acicular crystals, turning green on exposure to light and air, inodorous. Soluble in 50 parts of water and more soluble in alcohol (90 per cent.), the solutions being decomposed with production of a green color when they are boiled. Neutral or very feebly acid to solution of litmus. From solutions, solution of sodium bicarbonate throws down a precipitate which becomes green on standing and then forms a solution which is purple with ether, violet with chloroform, and bluish green with alcohol (90 per cent.). With dilute test-solution of ferric chloride it gives a deep red, and with nitric acid, a blood-red coloration. If the salt impart an emerald-green color to 100 parts of water, after shaking the mixture, it should be rejected.” Br. The alkaloid is colored dark red by nitric acid and rose red by ferric chloride, changing to violet, and finally black, on exposure. The aqueous and alcoholic solutions are at first colorless, if

heated becoming pinkish, but change rapidly to greenish, finally becoming deep emerald green in color. This change in color has been attributed to oxidation, and it has been noticed that the solution on standing loses its power; for this reason it is best not to keep the solution, but to make it as wanted. C. Bernbeck affirms that the change in the solution to a green color may be prevented by the addition of a small quantity of hydrochloric acid, the green coloration being due to ammonia. (*Ph. Ztg.*, 1885.)

According to Max Quehl and H. Koehler apomorphine is precipitated from its solutions greenish by tannic acid, lemon yellow by picric acid, bluish white, and turning to sap-green by copper sulphate on boiling, purplish by gold chloride, white, turning to blackish violet by potassium ferrieyanide on boiling, blood-red by iodine in solution of potassium iodide, the precipitate disappearing on boiling, white and curdy by potassium sulphocyanate. (*A. J. P.*, 1873, p. 166.) With potassium dichromate and concentrated sulphuric acid it turns a dark red; with the potassium salt alone, a deep yellow-orange; with neutral iron chloride, an amethyst color.

Uses.—Apomorphine hydrochloride was first brought forward as a prompt and safe emetic by Gee. It has the great advantages of smallness of dose and freedom from irritating properties, so that it can be used hypodermically. When from one-fifteenth to one-tenth of a grain (0.004 to 0.006 Gm.) of it is injected under the skin of a man, free emesis usually occurs in from 5 to 20 minutes; the dose may be repeated at intervals if necessary. The effects upon the general system are usually not marked; but in some cases very alarming syncope symptoms have been produced, and death is said to have resulted from one-sixteenth of a grain (0.004 Gm.) in a feeble adult worn out with chronic bronchitis and emphysema. (*Med. Rec.*, 1877, p. 664.) According to Harnack, young children bear the remedy very badly. Apomorphine hydrochloride is a valuable sedative expectorant, useful whenever it is desired to produce relaxation and increase of secretion. As an emetic, it has been employed in narcotic poisoning, to dislodge foreign bodies from the œsophagus, in suffocative catarrh, etc. In acute debauch, it is asserted that apomorphine hydrochloride is especially valuable as an emetic on account of producing a marked tendency to sleep after vomiting. Very alarming symptoms have followed the use of a solution which has undergone change, and fresh solutions only should be administered. Under no circumstances should more than one-fourth of a grain (0.016 Gm.) be given at a dose.

Dose, as an expectorant, one-twentieth to one-twelfth of a grain (0.003 to 0.005 Gm.); as an emetic, one-tenth to one-fourth of a grain (0.006 to 0.016 Gm.).

AQUA. U. S.

WATER

(ἀ'qua)

 $H_2O = 17.88$

"Potable Water in its purest obtainable state." U. S.

*Υδωρ, Gr.; Eau, Fr.; Wasser, G.; Acqua, It.; Agua, Sp.

Water has always been included in the U. S. Pharmacopœia, on account of its great importance as a medicinal and pharmaceutical agent. It was not admitted into the official lists of the British Pharmacopœias until 1839, when it was first recognized by the Edinburgh College, but it was dropped at the last revision of the British Pharmacopœia. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a substance of such diversified agency, our limits will allow of a sketch only of its properties and modifications. We shall speak of it under the several heads of *pure water*, *common water*, and *mineral waters*.

PURE WATER.—Water, in a pure state, is a transparent liquid, without color, taste, or odor. Its sp. gr. is assumed to be unity, and forms the term of comparison for that of solids and liquids. A cubic inch of it, at the temperature of 15.5° C. (60° F.), weighs very nearly 252.5 grains; when weighed in air with brass weights at 25° C. (77° F.) it weighs 251.91 grains. In the metric system the weight of 1 Ce. of distilled water taken at 4° C. (39.2° F.) is made equal to 1 gramme, the unit of weight in this system. It is compressible to a small extent, as was proved first by Canton, and afterwards, in an incontestable manner, by Perkins. Reduced in temperature to 0° C. (32° F.), it becomes a solid or ice, with the sp. gr. 0.9175 (Dufour, *C. R. A. S.*, Juin, 1860); and raised to 100° C. (212° F.), an elastic fluid called steam. In the latter state its bulk is increased nearly 1700-fold, and its sp. gr. so far lessened as to be not much more than half that of atmospheric air. At the temperature of 4° C., or 39.2° F., its density is at the maximum; and consequently, setting out from that point, it is increased in bulk by being either heated or cooled. It has the power of dissolving more or less of all gases, including the constituents of common air, which are always present in natural water in variable proportions. It uniformly exists in the atmosphere, in the form of invisible vapor.

Water consists of two atoms of hydrogen and one of oxygen; or, in volumes, of two volumes of hydrogen and one volume of oxygen condensed into two volumes of aqueous vapor or steam. On these data, it is easy to calculate the sp. gr. of steam; which will be 0.0693 (sp. gr. of hydrogen) + 0.5528 (half the sp. gr. of oxygen) = 0.6221.

COMMON WATER.—By reason of its extensive solvent powers, water, in its natural state, must be more or less contaminated with foreign matter. Thus, it becomes variously impregnated, according to the nature of the strata through which it percolates. When the foreign substances present are in so small an amount as not materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water*.

There are almost innumerable shades of difference in common water, as obtained from different localities and sources; but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but inconsiderable impurities, and which, when used in washing, forms a lather with soap. By a *hard water* is understood a variety of water which contains calcium or magnesium salts, through which it curdles soap, and is often unfit for domestic purposes. Solution of soap is a good test liquid for ascertaining the hardness of water. In distilled water it produces no effect; in soft water, only a slight opalescence; but in hard water, a milky appearance. The milkiness is due to the formation of an insoluble compound between the fatty acids of the soap and the lime or magnesia of the foreign salt. The hardness may be classed as temporary or permanent, as in waters which contain much free carbon dioxide, the hardness is removed or diminished by boiling, which causes a loss of the gas and a deposition of the calcium and magnesium salts which produce the hardness. The hardness may be estimated by means of a volumetric soap solution which is added in small quantities to a measured quantity of the water, shaking after each addition and noting the volume of the soap solution which is required to produce a lather which will remain on the surface for five minutes.

The most usual foreign substances in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbon dioxide, calcium sulphate, magnesium carbonate, and sodium chloride. Carbon dioxide is detected by lime water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off the dioxide. The presence of calcium sulphate is shown by precipitates being produced by barium nitrate, and, after ebullition, by ammonium oxalate. The former test shows the presence of sulphuric acid, and the latter, after boiling the water, indicates lime not held in solution by carbon dioxide. Calcium carbonate, when held in solution by an excess of carbon dioxide, may be detected by boiling the water, which causes it to precipitate; but even after ebullition and filtration the water will retain enough calcium carbonate to give a precipitate with lead acetate, calcium carbonate being itself to a minute extent soluble in water. Silver nitrate will produce a precipitate if any soluble chloride be present; and, ordinarily, the one present may be assumed to be common salt.

Arsenic in minute quantity has been found in water used as drink. At Whitbeck, in Cumberland, England, the inhabitants employ, both as drink and for culinary purposes, a water holding enough arsenic in solution to be quite sensible to tests, without any known injurious consequences. (*Chem. News*, 1860, p. 128.) Small amounts of iron and aluminum salts are frequently, and silica almost always, found in potable waters.

Clark has proposed to purify hard water, when the hardness arises from calcium bicarbonate, by a process which he calls *liming*. This consists in adding to the water sufficient lime water to convert the bicarbonate into the very sparingly soluble carbonate. This procedure renders the water soft, and gets rid of all the lime, except that in the minute portion of carbonate dissolved. The merit of this process consists chiefly, not in the removal of lime, but in preventing the formation of organic growths, principally *confervæ*, the decomposition of which renders the water offensive and unwholesome. River water containing the usual amount of calcareous matter, if allowed to stagnate in open reservoirs, in the summer, will become contaminated with myriads of microscopic plants and animals. This change is prevented, according to Clark, by his peculiar treatment, which deprives the living organisms of the nutriment derived from loosely combined carbon dioxide.

The oxygen and nitrogen present in neutral waters are not usually in the same proportion as in atmospheric air; the oxygen in atmospheric air amounts to about 20 per cent. in volume, while the usual gaseous mixture expelled from fresh water by boiling contains 32 per cent. (See table on page 163.) The important discovery has been made by Moore and Kellerman of the U. S. Department of Agriculture, that copper sulphate, if present in amounts such as 1 in 4,000,000 will be toxic to algæ, destroying them and preventing their reappearance; this statement has been confirmed by Gildersleeve (*Am. J. M. S.*, 1905, 129, p. 757), Stewart (*Am. J. M. S.*, 1905, p. 761), Kraemer (*A. J. P.*, 1906, 140), and others. They state that one part of copper sulphate in 100,000 of water will destroy typhoid and cholera germs in from three to four hours, and it appears to be established that waters not containing too large amounts of organic matter, exposed to the action of copper foil, kept in copper vessels, or treated with small amounts of copper sulphate (1 to 500,000) will destroy all typhoid bacilli and many other organisms in from 3 to 6 hours. On the other hand as shown by Doty (*N. Y. M. R.*, cxvii. p. 90), and Fowler (*Jour. Roy. Army Med. Corps*, 1905, v. 391), in the presence of even moderate quantities of organic matter the bactericidal power of copper is much reduced, while in foul waters it is almost nil. See "The Use of Copper in Destroying Typhoid Organisms and the Effects of Copper on Man," Henry Kraemer. (*A. J. P.*, 1905, p. 265.)

Common water is also divided into varieties according to its source. Thus, we have rain, snow, spring, river, well, lake, and marsh water.

Rain and snow water are the purest kinds of natural water. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields, at a distance from houses, and some time after the rain has commenced falling; otherwise it will be contaminated with the dust which floats in the atmosphere, and with other impurities derived from roofs. The rain water of large cities contains nitrogenized organic matter, as shown by the odor produced by burning the residue left after the water has been evaporated. In districts near the sea coast rain water usually contains appreciable quantities of chlorides.

Rain water ordinarily contains atmospheric air, and, according to Liebig, a little nitric acid, the amount of which is increased when the rain descends during a thunder storm. Chabrier states as the result of his observations that rain water contains either nitrous or nitric acid, the one or the other predominating according to the condition of the weather, the nitrous acid being relatively in excess in mild weather, but the nitric when the rain is attended with tempestuous winds. (*J. P. C.*, Janv. 1872, p. 42.) According to an analysis, made by Martin, of rain water which fell at Marseilles during a violent storm, 1000 parts by weight contained 0.004 of chlorine and 0.003 of ammonia. Not a trace of iodine or of nitric acid was discovered. Boussingault has ascertained that the rain which falls in towns contains considerably more ammonia than that which falls in the country. Thus the rain of Paris was found by him to contain three or four parts of ammonia per million, while that collected in a mountainous region contained about four-fifths of one part only in a million. The average results of J. B. Lawes and J. H. Gilbert give one part of ammonia to the million of rain water. Snow water has a peculiar taste, which was supposed to depend on the presence of air more oxygenated than that of the atmosphere; but in point of fact it contains no air, and this accounts for its rapid taste. Rain and snow water are sufficiently pure for most chemical operations.

Spring water (*aqua fontana*) depends entirely for its quality on the strata through which it flows, being purest when it passes through silicious sand or gravel, or where the prevailing rock formation is granitic. On the contrary, where the formation is limestone, the water will, because of the carbon dioxide dissolved in it, take up calcium carbonate and become what is called a *hard water*. It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River water (*aqua fluvialis*) is, generally speaking, less impregnated with saline matter than spring water, because made up in considerable part of rains, while its volume bears a larger proportion to the surface of its bed.

It is, however, much more apt to have mechanically suspended in it insoluble matters, of an earthy nature, like clay and silt, which impair its transparency. It is frequently rendered more sightly by being run through porous stone, carbon, or sand filters. The coarse particles are by this filtration removed; but sewage or injurious products resulting from decomposition which are dissolved in the water are not removed, so that such clean filtered water may be a very deadly poison. Water may be purified for manufacturing purposes by what is termed the alum process,—i.e., by adding 2 grains of alum to a gallon of water, and permitting the impurities to subside for 48 hours. (*Chem. News*, July 23, 1886.) River water is purified now (1906) at Philadelphia on the large scale by filtration in conjunction with sedimentation, at the lower Roxborough filter plant; the walls surrounding the preliminary filters are of concrete; ten of the filters are in operation, controlled separately so that one can be cleaned without interfering with another. The filtering material consists of several sizes of broken slag, arranged in layers according to size, the finer at the top because the unfiltered water enters from

gr., per Imperial gallon, of impurity in a well in London. (*P. J.*, 1856, p. 27.) The presence of nitrates in water is destructive to many forms of organic life. *Artesian Wells*, from their great depth, generally afford a pure water, although on analysis they frequently show a larger proportion of solid constituents on evaporation than do waters from rivers. *Lake water* cannot be characterized as having any invariable qualities. The water of most of the lakes in the United States is pure and wholesome.

Marsh water is generally stagnant, and contains vegetable remains undergoing decomposition. It is unwholesome, and ought never to be used internally.

All water which is exposed to the air dissolves a quantity of oxygen, nitrogen, and carbon dioxide, in obedience to the laws of gaseous absorption. It is indeed upon this dissolved oxygen that the life of water-breathing animals depends. In every pure water the proportion between the dissolved nitrogen and oxygen is found to be constant, and it is represented by the following numbers:—oxygen 34.91, and nitrogen 65.09 per cent.; 1000 Cc. of pure

	Thames water taken at					
	Kingston.	Hammer-smith.	Somerset House.	Greenwich.	Woolwich.	Erith.
	Cc.	Cc.	Cc.	Cc.	Cc.	Cc.
Total volume of gas per liter	52.7	. . .	62.9	71.25	63.05	74.3
Carbon dioxide	30.3	. . .	45.2	55.6	48.3	57.0
Oxygen	7.4	4.1	1.5	0.25	0.25	1.3
Nitrogen	15.0	15.1	16.2	15.4	14.5	15.5
Ratio of oxygen to nitrogen	1 : 2	1 : 3.7	1 : 10.5	1 : 60	1 : 52	1 : 8.1

the bottom; on the surface of the slag is placed a layer of sponge clippings one foot in thickness, but compressed to about six inches and held down by lattice work; the cleaning of the sponge layer is accomplished by suitable machinery. "Raw water" is filtered at the rate of 45,000,000 gallons per acre per day of such quality that it enables the hygienic filters to deliver clean and wholesome water at the rate of 6,000,000 gallons per acre per day. The hygienic filters are constructed of beds 4 inches in depth of sharp silicious sand laid upon gravel and broken stone graded in fineness; the coarser particles are at the bottom; the water is made to enter from below so as to avoid disarranging the particles of sand, for this, through the escape of air, would occur if the water was let in from the top. (*Toplis, A. J. P.*, 1902, p. 67, 1904, p. 116.) *Well water*, like that from springs, is liable to contain various impurities. As a rule, the purity of the water of a well will be in proportion to its depth and the constancy with which it is used. Well water in large cities always contains a large amount of impurity, both organic and inorganic, the result of sewage contamination. R. D. Thomson found 147.6

water, such as rain water, when saturated dissolves 17.95 Cc. of air. If the water be rendered impure by the introduction of organic matter undergoing oxidation, the proportion between the dissolved oxygen and nitrogen becomes different, owing to the oxygen having been partly or wholly used for the oxidation of this material. This is clearly shown in the above analysis made by Miller of the dissolved gases contained in Thames water collected at various points above and below London. The above table shows that whereas pure water at Kingston contains the normal quantity of dissolved oxygen, the ratio of nitrogen to oxygen increases at a very rapid rate as the river water becomes contaminated with London sewage, but that this ratio again shows signs of a return to the normal at Erith. Moreover, carbon dioxide should not constitute more than from 8 to 10 per cent. of the dissolved gases in a pure water, but in these cases it has become 60 per cent. or over of the gases as obtained from the water for analysis. Hence it is clear that an analysis of the gases dissolved in water may prove of much help in ascertaining whether the water is pure or

whether it has been contaminated with putrescent organic matter. Indeed, Miller concludes that whenever the proportion between dissolved oxygen and nitrogen falls to less than 1 to 2 the water is unfit for drinking purposes. (Roscoe and Schorlemmer, *Treatise on Chem.*, i. 245.)

The second class of dissolved impurities consists of inorganic salts, even rain water washing some of these out of the atmosphere. It invariably contains ammoniacal salts, sodium chloride, and particles of organic matter, living and dead. In towns the rain water also contains a larger proportion of nitrates than that falling in the country. It is, however, the spring waters especially which contain the largest amount of mineral matter in solution. The salts which most commonly occur in solution in spring water are: (1) Calcium, magnesium, iron, and manganese carbonates, dissolved in an excess of carbon dioxide. (2) Calcium and magnesium sulphates. (3) Alkaline carbonates, chlorides, sulphates, nitrates, or silicates.

Spring waters which issue from considerable depths, or which originate in volcanic districts, are always hotter than the mean annual temperature of the locality where they come to the surface.

The term *Aqua*, in the United States Pharmacopœia, may be considered as designating any natural water of good quality which answers well for cooking and does not curdle soap. "A colorless, limpid liquid, without odor or taste at ordinary temperatures, and odorless when heated. Water should be perfectly neutral to litmus paper. 1000 Cc., when concentrated by evaporation to 20 Cc., should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). On evaporating 1000 Cc. of Water on a water-bath, it should not leave a residue weighing more than 0.5 Gm. (limit of *soluble salts*), and this residue, when ignited, should not carbonize, nor evolve *ammoniacal* or *acid* vapors. If 200 Cc. of Water be acidulated with hydrochloric acid, heated to boiling, and 0.5 Cc. of barium chloride T.S. be added, the liquid, when cooled and filtered, should give no further precipitate on the addition of a few drops of barium chloride T.S., even on standing (limit of *sulphates*). If 200 Cc. of water be acidulated with nitric acid, heated to boiling, and 0.5 Cc. of tenth-normal silver nitrate V.S. be added, the liquid, when cooled and filtered, should not be affected by the subsequent addition of a few drops of silver nitrate T.S. (limit of *chlorides*). If 10 Cc. of Water mixed with a few drops of diphenylamine T.S. be carefully poured upon about 3 Cc. of sulphuric acid, free from nitrous compounds, contained in a test-tube, so as to form a separate layer, no blue color should be formed at the line of contact of the two liquids (limit of *nitrates*). If to 50 Cc. of Water contained in a glass cylinder 2 Cc. each of sulphuric acid T.S. and naphthylamine acetate T.S. are added, and the solution well mixed, no

distinct pink coloration should appear within five minutes, if the cylinder be placed upon a white surface and viewed from above (limit of *nitrates*). If to 50 Cc. of Water contained in a glass cylinder 2 Cc. of alkaline mercuric potassium iodide T.S. (Nessler's Reagent) be added and thoroughly mixed, no yellow or brownish tint should be produced immediately; the cylinder should be placed upon a white surface and viewed from above (limit of *ammonia*). On heating to boiling 100 Cc. of Water, acidulated with 10 Cc. of diluted sulphuric acid, and subsequently adding 0.4 Cc. of tenth-normal potassium permanganate V.S., the pink color of the liquid should not be completely destroyed after it has been boiled for ten minutes (limit of *organic* or *other oxidizable substances*)," *U. S.*

The British Pharmacopœia no longer includes "*Aqua*;" it recognizes "*Aqua Destillata*," and gives appropriate tests. (See page 178.)

Water should never be kept in leaden cisterns, on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to the softness and purity of the water; for it is found that the presence of a minute proportion of saline matter, as for example of calcium sulphate, protects the water from the slightest metallic impregnation. The chlorides are not protective, as they give rise to lead chloride, which is slightly soluble. The protection has been ascribed to an insoluble film on the surface of the lead, formed by the decomposition of the saline matter. Upon this principle is based a plan of protection by Schwartz of Breslau, who proposes to fill leaden pipes through which water is conducted, with a strong solution of an alkaline sulphide, which forms a perfectly insoluble coating of lead sulphide (*sulphuret*), said to be quite impermeable by the water afterwards introduced. (*Chem. News*, 1863, p. 157.) Galvanized iron (zinc coated) does not rust as readily as iron which is unprotected, because as the zinc has the greater solution tension it protects the iron, which remains unacted upon. On the other hand, tinned iron (tin plate) rusts more readily than iron alone if the iron is exposed at any point; the iron being the anode end is at once attacked. A. Wynter Blyth proposed a simple test for lead in drinking-water. A solution of cochineal is made by boiling cochineal in water, filtering, and adding a little alcohol to preserve it. A few drops of this solution are added to the water, which, if acid, must be rendered neutral by a trace of alkali; if lead be present, even in the proportion of one-tenth of a grain in a gallon of water, a mauve-blue color will develop, its depth depending upon the quantity of lead in the water. (*Am. Drug.*, 1884, p. 93, from *The Analyst*.)

A very important class of dissolved impurities is made up of organic compounds. This organic matter may be derived from a vegetable source, such as leaf-mould and the decomposition products of wood, in which case it is

practically harmless, or it may be derived from animal sources, in which case it almost always proves a serious impurity.

The careful observations of students of public health leave no doubt that a number of epidemic diseases, especially cholera and typhoid fever, are often contracted and spread by means of drinking water contaminated with germs of disease from excreta and general sewage. This impure water may be clear and may have filtered through considerable distances of soil, and yet may contain these poisonous germs. Now, nitrogen is one of the characteristic constituents of animal matter as contrasted with vegetable matter, relatively few forms of which contain it, and those are of a character not likely to be found in natural waters. Hence, if water should be impregnated with animal matter, this would be indicated by the presence of nitrogen in solution, either in the form of albumin or albuminous matter, if the animal matter in the water is still unchanged, or, if the animal matter has undergone oxidation, in the form of ammonia or nitrous or nitric acid.

There are, therefore, to be determined in the examination of a water with reference to this presence of organic nitrogenous matter, (1) the ammonia, (2) the unchanged albuminous matter, which, as it is changed into and determined as ammonia, is called "albuminoid ammonia," and (3) the nitrates and nitrites present.

The ammonia is first determined by distilling the water made alkaline with sodium carbonate as long as the distillate carries enough ammonia to be recognized by *Nessler's solution*. (See PART III.) For this purpose the distillate is collected successively in volumes of 50 Cc. and the amount of ammonia in each of these separate distillates determined. The smallest quantity of ammonia will produce a yellow color, the tint of which is to be compared with that obtained from the Nessler solution treated with a standard ammonium chloride solution.

After the free ammonia has been distilled off, a solution of sodium hydroxide and potassium permanganate is added and the distillation is

continued. Another portion of ammonia now comes off, owing to the action of the permanganate on the nitrogenous organic matter. The amount of ammonia thus obtained is determined, and is tabulated as "albuminoid ammonia," because albumin is one of the bodies which is decomposed in this way. L. de Konnick found that the Nessler test in ammoniacal liquids does not produce the usual yellowish-brown precipitate, nor even a coloration, in the presence of alcohol. (*Am. Drug.*, 1893, p. 386.)

Instead of this method proposed by Wanklyn and Chapman, another process, described by Frankland and Armstrong, is often used. In this case, the water having been evaporated, the dry residue is submitted to an organic combustion analysis, which gives the "organic nitrogen" and the "organic carbon," and the ratio of these gives an indication as to the presence of albuminous matter rich in nitrogen. If the amount of albuminoid nitrogen indicated by either of these processes exceed 0.15 part for one million of water, the latter should be rejected as a drinking water. In some large towns, however, the surface well waters have shown albuminoid nitrogen to the amount of 0.3 to 0.8 part per million. Such waters are little better than sewage. The free ammonia, moreover, should not exceed 0.08 part per million, or the water must be considered as containing sewage contamination.

Nitrates may be estimated by the following process: A measured volume (15 to 25 Cc.) of the water is evaporated just to dryness in a flat-bottomed porcelain dish, 1 Cc. of phenoldisulphonic acid (made by heating 37 grammes of strong sulphuric acid with 3 grammes of pure phenol for 6 hours in a water bath) is added and thoroughly mixed with the residue by means of a glass rod. It is then diluted with about 25 Cc. of water, solution of ammonium hydroxide added in excess and the volume of the solution made up to 50 Cc. The nitrates present in the residue convert the phenoldisulphonic acid into picric acid, which, by the action of ammonium hydroxide forms ammonium picrate; this imparts to the

These figures are taken from official reports and do not represent averages of large numbers of analyses, but individual analyses of samples representative of the supplies. The figures for Boston water represent the Cochituate and Mystic Rivers respectively. The Little Rock supply is in the unfiltered condition; much of the solid matter is in suspension.

solution a yellow color which is proportional in its intensity to the amount of nitrates present in the water, and by carrying out a similar test with a standard solution of potassium nitrate similarly evaporated, the amount may be accurately estimated. Nitrites may be estimated by the sulphanilic acid and naphthylamine acetate test given for the qualitative detection of nitrites by the U. S. Pharmacopœia (see page 164), by carrying out a similar test with a standard solution of sodium nitrite and making a comparison of the relative intensity of the color which is produced in each.

The determination of chlorides is also frequently of great importance, for although mineral waters may be rich in chlorides, ordinary well waters or river waters, which are the chief sources of supply, will not contain much chlorine unless they have been contaminated. Both urine and sewage may contribute this chlorine, as they are highly charged with sodium chloride. As a rule, it may be said that water containing more than two grains of chlorine per gallon must be looked upon with suspicion, unless some good reason for the presence of sodium chloride can be assigned.

The analyses (see table page 165) of the water supplied to several American cities are taken from Henry Leffman's *Manual of Water Analysis*, 4th ed. 1900.

MINERAL WATERS.—When natural spring waters are so far impregnated with foreign substances as to have a decided taste, and to operate in a peculiar manner upon the human economy, they are called *mineral waters*. These are conveniently arranged under the heads of *carbonated*, *alkaline*, *sulphureted*, *saline* (including *magnesian*, *chalybeate*, and *chlorinated*), and *silicious*. For a more comprehensive and detailed classification of this class of waters see *Mineral Waters of the United States*, U. S. Department of Agriculture, Bulletin No. 91.

1.—*Carbonated waters* are cold, and are characterized by containing an excess of carbon dioxide, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain calcium, magnesium, and iron carbonates, which are held in solution by the excess of carbon dioxide. The waters of Selters, Spa, Apollinaris, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class. For Artificial Carbonic Acid Water, the reader is referred to page 168.

2.—*Alkaline waters* contain a large quantity of sodium bicarbonate, as well as common salt and Glauber's salt. These are sometimes warm, such as the springs at Ems and Vichy, but generally cold. Gettysburg spring water is of this class.

3.—*Sulphureted waters* are such as contain hydrogen sulphide, and are distinguished by the peculiar fetid odor of that gas, and by yielding a brown precipitate with the salts of lead or silver. Examples of this kind are the

waters of Aix-la-Chapelle and Harrogate in Europe, and those of the White, Red, and Salt sulphur springs in Virginia.

4.—*Saline waters* are those the predominant properties of which depend upon saline impregnation. The salts most usually present are sodium, calcium, and magnesium sulphates and carbonates, in which latter case the name *magnesian* is given to them, the presence of the chlorides of these alkalies making the class *chlorinated waters*, which reach their maximum concentration in sea waters; while the presence of ferrous salts makes another class, the *chalybeate*. Among magnesium waters may be mentioned those of Friedrichshall, Hunyádi Janos, and Epsom; among chalybeate waters, those of Tunbridge and Brighton in England, of Pyrmont, Wiesbaden, and Spa on the Continent, and of Bedford, Pittsburg, and Brandywine in the United States. Potassium sulphate is occasionally present, and lithium has been detected by Berzelius in Carlsbad and other salt springs of Germany, and is also found in some American spring waters. Boric acid, usually in the form of an alkaline borate, is of frequent occurrence in mineral waters of certain portions of the United States. Cæsium and rubidium have also been detected in certain mineral waters, such as the Dürkheim and Baden-Baden waters, in the former of which these elements were first discovered by Bunsen. Bromine is found in the saline at Theodorshall, in Germany, as also in the salt wells of Western Pennsylvania, Ohio, Michigan, and West Virginia. The mineral springs at Saratoga contain a small proportion of iodine and bromine. The principle saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and Harrodsburg and Saratoga in the United States.

5.—*Silicious waters* are those in which the contents consist chiefly of alkaline silicates, such as the hot spring waters of Iceland and the geysers of Fire-hole Basin and Gardiner's River, Yellowstone National Park, U. S.

6.—*Sea water (English Channel)*.—In a thousand grains: water 964.744 gr.; sodium chloride 27.059; potassium chloride 0.765; magnesium chloride 3.667; magnesium bromide 0.029; magnesium sulphate 2.296; calcium sulphate 1.407; calcium carbonate 0.033. Total 1000 gr. (Schweitzer.) The proportion of sodium chloride is from 36 to 37 parts in 1000 in the ocean, at a distance from land. Its amount is small in the interior of the Baltic. It is perceived that bromine is present in very minute amount, 100 pounds of sea water yielding only $3\frac{1}{2}$ gr. of this element. Iodine exists in the water of the Mediterranean, and it has been found in ocean water. Besides these ingredients, others are alleged to exist in minute proportion in sea water, as fluorine by G. Wilson; lead, copper, and silver by Malaguti, Durocher, and Sarzeau; and iron and manganese by Uziglio. Gold in very minute quantity has been found in sea water. Prior to Wilson's researches, Middleton and Silliman, Jr., had

inferred the existence of fluorine in sea water, from its presence in marine animals. The lead and copper above mentioned were found in certain fuci only, the silver in the sea water itself. The presence of silver in sea water has been demonstrated by F. Field, by a comparative analysis of the same copper sheathing, when new, and after having been on a vessel for many years. The old sheathing was always found to contain more silver than the new; and the observations of Field have been subsequently confirmed by others. Schweitzer's analysis gives a small proportion of calcium carbonate, but Bibra could not detect any. John Davy's examinations of sea water show that calcium carbonate does not exist at a great distance from land, except in very minute proportion, but becomes quite evident at a distance of from fifty to a hundred miles from coasts. Boric acid has been found by Veatch in the sea water on the coast of California. (See *A. J. P.*, 1860, p. 330.)¹

Sea water, filtered, and charged with five times its volume of carbon dioxide, forms, according to Pasquier, a gentle purgative, which keeps very well, and is not disagreeable to take. The dose is from half a pint to a pint.

By freezing, sea water is almost entirely freed from saline matter, the ice being nearly pure water. It is obvious that the unfrozen water contains much more than its ordinary proportion of salts; and this is one of the methods of concentrating this and other saline solutions.

Medicinal Properties of Water.—Water is a remedy of great importance. When taken into the stomach, it acts by its temperature, by its bulk and by being absorbed. When of the temperature of about 15.5° C. (60° F.), it gives no positive sensation either of heat or cold; between 15.5° C. (60° F.) and 7.2° C. (45° F.), it creates a cool sensation; and below 7.2° C. (45° F.), a decidedly cold one. Between 15.5° C. (60° F.) and 37.7° C. (100° F.), it relaxes the fibres of the stomach, and is apt to produce nausea, particularly if the effect of bulk be added to that of temperature. By its bulk and solvent powers, it allays irritation of the stomach and bowels, by diluting the acrid contents and favoring their final expulsion, and by its absorption it promotes perspiration and the secretion of urine.

Water externally applied as a bath is also an important remedy. It may act by its own specific effect as a liquid, or as a means of modifying the heat of the body. It acts in the latter way differently, according to the temperature at which it may be applied. When this is above 36.1° C. (97° F.), it constitutes the vapor or hot bath; when between 36.1° C. (97° F.) and 29.4° C. (85° F.), the warm bath; between 29.4° C. (85° F.) and 18.3° C. (65° F.), the tepid bath; and between 18.3° C. (65° F.) and 0° C. (32° F.), the cold bath.

The general action of the *vapor* bath is to accelerate the circulation, and produce profuse sweating. It acts locally on the skin, by softening and relaxing its texture. In stiffness of the joints, and in various diseases of the skin, it has often proved beneficial.

The *hot bath*, like the vapor bath, is decidedly stimulant. By its use the pulse becomes full and frequent, the veins turgid, the face flushed, the skin red, and the respiration quickened. If the temperature be high, and the constitution peculiar, its use is not without danger, as it is apt to produce a feeling of suffocation, violent throbbing in the temples, and vertigo with tendency to apoplexy. When it acts favorably, it produces profuse perspiration.

The *warm bath*, though below the animal heat, nevertheless produces a sensation of warmth, as its temperature is above that of the surface. It diminishes the frequency of the pulse, renders the respiration slower, lessens the heat of the body, and relaxes the skin. It cannot therefore, be deemed a stimulant. By relieving certain diseased actions and states, accompanied by morbid irritability, it often acts as a soothing remedy, producing a disposition to sleep.

The *tepid bath* is not calculated to have much modifying influence on the heat of the body. Its peculiar effects are to soften and cleanse the skin, and to promote insensible perspiration.

The *cold bath* acts differently according to its temperature and manner of application, and the condition of the system to which it is applied. When of low temperature and suddenly applied, it acts primarily as a stimulant, by the sudden and rapid manner in which the heat is abstracted; next as a tonic, by condens-

¹ The following analysis of sea water, taken at two leagues from Fécamp, on the coast of France, merits special notice from the care with which it was made, and the large quantity operated on. The sp. gr. was 1.026, at 57° F.

ing the living fibres; and finally as a sedative. It is often useful in diseases of relaxation and debility, when practiced by affusion or plunging. But it is essential to its efficacy and safety that the stock of vitality should be sufficient to create, immediately after its use, those feelings of warmth and invigoration included under the term reaction. In febrile diseases with high bodily temperature the use of the cold bath is a very important therapeutic measure. For details as to method of use, see 13th edition of H. C. Wood's *Therapeutics*.

Cold water is frequently applied as a sedative in local inflammations, and as a means of restraining hemorrhage. Its use, however, is scarcely admissible in inflammations of the chest.

AQUA ACIDI CARBONICI, *Carbonic Acid Water*, or *Soda Water* (so called), (*Aqua acidula simplicior*, F. P.; *Eau gazeuse simple*, Fr.; *Kohlensäurewasser*, G.), which was formerly official in the U. S. Pharmacopœia, consists of water highly charged with carbonic acid.

Preparation.—Water is found to take up its volume of this gas under the pressure of the atmosphere; and Henry ascertained that precisely the same volume of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. From the principles above laid down it follows that, to saturate water with five times its volume of carbon dioxide, it must be subjected to a pressure of five atmospheres. Carbonic acid gas compressed into the liquid state is now manufactured on an immense scale and supplied in 20 pound and 50 pound steel cylinders. This allows of convenient transportation, and the purity of the gas is usually excellent.

Carbonic acid water is familiarly called in this country "*mineral water*" and "*soda water*;" the latter name, originally applied to the preparation when it contained sodium carbonate, being from habit continued since the alkali has been omitted.

Carbonic acid water is dispensed in most of the pharmacies in this country. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the store, and to terminate in a draught tube, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, or a series of block tin pipes called coolers, placed inside the counter apparatus, and surrounded with ice.

Properties.—Carbonic acid water is a sparkling liquid, possessing an agreeable pungent, acidulous taste. It reddens litmus deeply from

its state of concentration, and is precipitated by lime water in excess. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong vessels or in strong well-corked bottles placed inverted in a cool place. Several natural waters are of a similar nature, such as those of Selters, Spa, Pyrmont, Apollinaris, etc., but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the fountain well protected on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the tubes and stop-cocks. Iron fountains lined with a hard enamel are preferred to those of copper, but the best fountains are made of cast steel, lined with block tin. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. Tubes of pure tin are free from objection, and should be exclusively used.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting the interior, owing to the solder joint which permanently unites the two sections of the fountain. Sometimes drops of solder and chips of copper are carelessly left in the fountain, and form an additional source of danger. There can be no doubt that carbonic acid water is not unfrequently rendered poisonous by metallic impregnation. R. O. Doremus has proved by a chemical examination that lead and copper are sometimes present. (*A. J. P.*, 1854, p. 422; from the *Am. Med. Monthly*.) John T. Plummer of Richmond, Ind., has found lead. The latter metal is detected by hydrogen sulphide, which gives with it a black precipitate, and copper by potassium ferrocyanide, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper, when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid. Fortunately copper fountains have largely gone out of use, having been supplanted by those made of steel.

Uses.—Carbonic acid water is a grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, magnesium sulphate, and the saline cathartics generally, rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the

chances of their being retained. When used for this purpose, six or eight fluidounces (178 to 236 Cc.) will be sufficient.

AQUA AMMONIAE. U. S. (Br.)

AMMONIA WATER

(ā'quā am-mō'nī-ā)

"An aqueous solution of Ammonia [$\text{NH}_3 = 16.93$] containing 10 percent., by weight, of gaseous ammonia. This solution deteriorates on keeping, and should be tested frequently. It must not be dispensed for medicinal purposes if it contains less than 10 percent., by weight, of the gas. Ammonia water should be kept in glass-stoppered bottles, in a cool place." *U. S.* "An aqueous solution containing 10 percent. by weight of ammonia, NH_3 ." *Br.*

Liquor Ammonia, Br.; Solution of Ammonia; Water of Ammonia; Spiritus Salis Ammoniaci Causticus, Ammoniaque liquide officinale, *Fr. Cod.*; Eau (Solution, Liqueur) d'Ammoniaque, *Fr.*; Liquor Ammonii Caustici, *P. G.*; Salmiakgeist, Aetzammoniak, Ammoniak-Flüssigkeit, *G.*; Ammoniac, *It.*; Amoniaco, Amoniaco liquido, *Sp.*

The U. S. Pharmacopœia (8th Rev.) omits a process for preparing Ammonia Water. The U. S. P. 1870 contains an excellent process, which is as follows: "Take of Chloride of Ammonium, in small pieces, Lime, each, *twelve troyounces*; Water *six pints*; Distilled Water a *sufficient quantity*. Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Chloride of Ammonium. Place the retort on a sand-bath, and adapt to it a receiver purposely connected with a two-pint bottle, by means of a glass tube, reaching nearly to the bottom of the bottle, and containing a pint of Distilled Water. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0.960. Lastly, keep the liquid in small bottles, well stopped." *U. S.* 1870.

"Strong Solution of Ammonia, 1 *pint* (Imperial measure) or 500 cubic centimetres; Distilled Water, 2 *pints* (Imp. meas.) or 1000 cubic centimetres. Mix." *Br.*

The title of this preparation was changed, at the revision of the U. S. Pharmacopœia in 1860, from *Liquor Ammonia* to *Aqua Ammonia*, that it might conform in name as well as character with the Waters, among which the official preparations consisting of aqueous solutions of gaseous bodies are included. In the revision of 1890 the English name was changed from Water of Ammonia to Ammonia Water.

In the U. S. P. 1870 process, the ammonium chloride is decomposed by the superior affinity

of the lime for its acid, ammonia is disengaged, and the lime, combining with the acid, forms calcium chloride and water,

This differs from the 1850 process in introducing the materials into the retort with a large quantity of water, instead of in the dry state. In both cases the gas is driven over by heat, but in the moist plan it is accompanied with more aqueous vapor than in the dry. If the object were to obtain ammonia water in the highest concentrated state, there might be some advantage in the dry method; but, as a weak solution is contemplated, the wet method is equally efficient, while in all respects it is more convenient, and productive of better results, for, according to E. R. Squibb, the ammonia water made by the older official process has invariably an empyreumatic odor, from which that made by the present process is free. (*Proc. A. Ph. A.*, 1858, p. 407.) The receiver is intended to retain any water holding in solution undecomposed chloride, or the oily matter sometimes contained in the salt, as well as other impurities, which may be driven over by the heat while the pure gas passes forward into the bottle containing the distilled water, which should not fill it, on account of the increase in the bulk of the water during the absorption of the gas. The tube should extend to near the bottom of the bottle, and pass through a cork loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's safety tube.

In preparing solution of ammonia, equal weights of ammonium chloride and lime are used for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the molecular weights; but in practice it is found advantageous to have an excess, in order to insure the full decomposition of the ammonium chloride, as well as to make up for accidental impurities in the lime.

The British Pharmacopœia gives directions for diluting *Liquor Ammonia Fortior* so as to reduce it to the strength of *Liquor Ammonia*. This is effected by mixing one measure of their stronger preparation with two measures of distilled water. The ammonia water of commerce is known as "*Aqua Ammonia F. F.*," or "20° ammonia;" it may be diluted by adding 2 volumes of water to 4 volumes of 20° ammonia water to make official ammonia water. Ammonia water of other strengths may be diluted by consulting the table given on page 171, and applying the rules given in Remington's *Practice of Pharmacy*, 4th ed., p. 98.

Properties.—Ammonia water is "a colorless, transparent liquid, having a very pungent, characteristic odor, a caustic alkaline taste, and a strongly alkaline reaction upon red litmus paper. Specific gravity: 0.958 at 25° C. (77° F.). It is completely volatilized at 100° C. (212° F.). On bringing a glass rod dipped

into hydrochloric acid near cold Ammonia Water, dense white fumes are produced. On slightly supersaturating 10 Cc. of Ammonia Water with diluted sulphuric acid, no *empyreumatic odor* or red color should be developed, and if to this liquid 0.1 Cc. of tenth-normal potassium permanganate V.S. be added, the pink color should not be completely destroyed within ten minutes (absence of *readily oxidizable substances*). If Ammonia Water be mixed with 4 times its volume of calcium hydroxide T.S., it should not afford an immediate turbidity (absence of more than minute traces of *carbonic acid*). When neutralized and made slightly acid with hydrochloric acid, Ammonia Water should not respond to the Time-Limit Test for *heavy metals* (see Part III, Test No. 121). If Ammonia Water be slightly supersaturated with nitric acid, it should not be affected by barium chloride T.S. (absence of *sulphates*), nor by silver nitrate T.S. (*chlorides*); and if a third portion of the acidulated liquid be evaporated on a water-bath to dryness, it should afford a colorless residue which on ignition should be completely volatilized (absence of *coal-tar bases* and of *fixed impurities*). Introduce into a stoppered weighing-bottle 3 Cc. of Ammonia Water and weigh accurately. Dilute with 50 Cc. of distilled water and titrate with normal sulphuric acid V.S., using litmus or methyl-orange T.S. as indicator. Multiply the number of Cc. of the normal sulphuric acid V.S. consumed, by 1.693, and divide this product by the weight of the Ammonia Water taken; the quotient represents the percentage of ammonia gas." *U. S.* Of the British preparation, "each gramme should require for neutralization 5.9 cubic centimetres of the *volumetric solution of sulphuric acid*. It should respond, qualitatively, to the characters and tests described under 'Liquor Ammoniae Fortis.' Specific gravity 0.959." *Br.*

Ammonia Water is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, barium, or strontium, and only partially decomposes those of magnesium. Commercial solution of ammonia sometimes contains *pyrrol*, *naphthalene*, *aniline*, and *pyridine*. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with hydrochloric acid, by its tingeing a slip of fir wood of a rich purple color, characteristic of pyrrol. (MacLagan.) The source of these impurities is coal gas liquor, from which the ammonia compounds are largely obtained. Donath (*Dingler's Polytechnisches Journal*, vol. iv. p. 229) tested some ammonia prepared from gas liquor, by neutralizing with diluted sulphuric acid, when the liquid assumed a rose color, and a solution of the sulphate emitted the characteristic odor of naphthalene.

Composition.—Water is capable of absorbing 670 times its volume of ammonia gas at 10° C. (50° F.), and increases in bulk about two-thirds. But the official solution of ammonia is

by no means a saturated one. Thus, the ammonia contained in the *U. S.* preparation is about 10 per cent. The official table on page 171 gives the percentage of ammonia gas in aqueous solutions of different densities at the temperature of 25° C. (77° F.) and 15° C. (59° F.).

Uses.—When brought into contact with living tissue, ammonia acts as a stimulant, irritant, or caustic, according to the strength of its solution. When applied to the skin, it may excite simply burning pain and redness, but in the form even of the present preparation, if the contact be sufficiently maintained, it is capable of destroying the whole dermal tissue; taken internally in a concentrated form, it acts as a violent corrosive poison, and may cause rapidly fatal gastro-enteritis, with the destruction of the visceral coats. In some cases it has produced death in a few minutes by entering the larynx and causing oedema, with consequent suffocation. When taken internally in therapeutic doses its action is immediate, and continues but for a few moments. In the stomach it acts as a stimulant antacid, and is often useful in *heartburn*, *sick headache*, etc. After absorption it stimulates most powerfully the circulation and respiration, affecting especially the heart and respiratory centres. By full doses the respiratory rate and the arterial pressure are for a few moments enormously increased. Toxic doses are directly paralyzing to the heart muscle, and may cause, if injected into a vein, immediate diastolic arrest of the heart. According to Bence Jones, ammonia is oxidized in the system, with the formation of nitric acid, which is eliminated by the kidneys.

Ammonia water is a valuable remedy in all forms of sudden *syncope*. The injection of ammonia into a vein was brought forward by G. B. Halford of Melbourne, as a specific against the *poison of serpents*, and some evidence has been adduced as to its value. As long ago, however, as 1782, Fontana published at Florence a series of experiments showing the uselessness of such injections as a remedy for *snake-bite*, and the subject has been investigated in India by Sir Joseph Fayrer (*Ind. Ann. Med. Sci.*, 1872), and by a Royal Commission (*L. L.*, Sept. 1874), with the result of completely establishing the truth of the experiments and conclusions of Fontana. In *collapse* following severe accident, or in sudden *cardiac failure* from other acute cause, the intravenous injection of ammonia water has been of the greatest service in arousing the action of the heart. Half a drachm to a drachm diluted with half an ounce to an ounce of water may be slowly thrown directly into a vein. In some cases the drug has been simply used hypodermically, but is almost certain to cause severe local symptoms. On account of its cheapness, ammonia water is much used as an ingredient in stimulating liniments, especially combined with olive or other oil.

Dose, ten to thirty minims (0.6 to 1.8 Cc.), largely diluted.

Table of Percentage and Specific Gravity of Ammonia. U. S. P. (8th Rev.).

AQUA AMMONIÆ FORTIOR.**U. S. (Br.)****STRONGER AMMONIA WATER**

(ä'quä am-mö'nä-e för'ti-ör)

"An aqueous solution of Ammonia [NH₃ = 16.93] containing 28 percent., by weight, of gaseous ammonia. This solution deteriorates on keeping, and should be tested frequently. Stronger Ammonia Water should be kept in partially filled, strong, glass-stoppered bottles, in a cool place. Great caution should be used in handling this liquid." *U. S.* "An aqueous

solution containing 32.5 per cent. by weight of ammonia, NH_3 . It may be obtained by heating a mixture of ammonium chloride and slaked lime, and passing the resulting ammonia into distilled water." *Br.*

Liquor Ammonia Fortis, Br.; Strong Solution of Ammonia; Eau d'Ammoniaque forte, *Fr.*; Stärker Salmakeist, *G.*

This preparation is too strong for internal exhibition, but forms a convenient ammoniacal solution for reduction, by dilution with two measures of distilled water, to the strength of ordinary Ammonia Water, or for preparing strong rubefacient liniments.

The U. S. Pharmacopœia does not give a process. The process of the British Pharmacopœia (1885) will be found in detail in the U. S. D., 17th ed., p. 202.

Stronger Ammonia Water is seldom made by this process, but is prepared on a large scale, from one of the products of the coal gas manufacture, by the more economical process of distilling *gas liquor*; the distillate, which is principally ammonium sulphide, is then converted into ammonium sulphate by sulphuric acid. The sulphate is gently distilled with milk of lime, the still being connected with a series of glass carboys, arranged like Woulf's bottles, and three-fourths filled with distilled water. In this way solution of ammonia may be obtained of maximum strength. It is also made by diluting the concentrated liquid ammonia.

Properties of Aqueous Ammonia of Maximum Strength.—This is a colorless liquid, of an acrid taste and very pungent odor. It is strongly alkaline, and immediately changes the color of turmeric, when held over its fumes, to reddish brown. Cooled to 40°F. below zero, it concretes into a gelatinous mass, and at 54°C. (130°F.) boils, owing to the rapid disengagement of the gas. Its sp. gr. is 0.875 at 10°C. (50°F.) Anhydrous ammonia is said to dissolve metallic sodium, and the solution is intensely blue. (*Chem. News*, Nov. 4, 1870, p. 217.)

Anhydrous liquefied ammonia is now an article of commerce, being used on a large scale in the manufacture of artificial ice and in refrigerating plants, where the cold produced by its rapid evaporation under a partial vacuum is utilized to furnish the necessary lowering of temperature. The apparatus used for its production is almost identical with that employed in the manufacture of liquid carbon dioxide, and consists of a combination of vacuum and condensing pumps. The gas is obtained from the strongest ammonia water by heating, with application of a partial vacuum, and must be well dried before the compression. To obtain a pure product, it has been found best to allow the liquefied ammonia to expand several times in a gasometer, in which case, the larger part of the impurities are left behind in liquid form. These consist of water, alcohol, acetone, traces of the lubricating oil from the compressing pumps, and a little ammonium carbonate.

In ammonias made from the distillation of bones, pyridine is also found to occur as an impurity. Liquefied ammonia comes into commerce in steel cylinders which have been tested to stand 100 atmospheres internal pressure, and are provided with well fitting screw valves.

Properties of the Official Stronger Ammonia Water.—This has similar properties to those above mentioned. Its sp. gr. is 0.897 at 25°C. (77°F.), *U. S.*, 0.891, *Br.* When of the former density, it contains 28 per cent. of the gas; when of the latter, 32.5 per cent. It is "a colorless, transparent liquid, having an excessively pungent odor, a very caustic and alkaline taste, and a strongly alkaline reaction upon red litmus paper. Specific gravity: 0.897 at 25°C. (77°F.) If Stronger Ammonia Water be diluted with twice its volume of distilled water, it should respond to the reactions and tests described under *Aqua Ammonia*. The percentage of ammonia gas in Stronger Ammonia Water should be determined by the same test as that given under *Aqua Ammonia*." *U. S.* The stronger ammonia water of commerce usually ranges in density from 0.900 to 0.920. Even when of proper official strength at first, it gradually becomes weaker by the escape of ammonia. To prevent its deterioration, it should be kept in closely-stoppered bottles in a cool place. If precipitated by lime water it contains carbon dioxide. After having been saturated with nitric acid, a precipitate by ammonium carbonate indicates earthy impurity, by silver nitrate, a chloride, and by barium chloride, a sulphate. "When mixed with an equal volume of water, with the addition of a slight excess of hydrochloric acid, no color or odor should be developed (absence of tarry matters). It should not yield any characteristic reaction with the tests for arsenium, lead, iron, aluminium, zinc, calcium, magnesium, potassium, sodium, carbonates, sulphates, or sulphides, and only the slightest reactions with the tests for chlorides. Specific gravity 0.891. Each gramme should require for neutralization 19.1 cubic centimetres of the volumetric solution of sulphuric acid." *Br.*

When purchasing the Stronger Solution of Ammonia, the apothecary should not trust to its being of the official strength, but should ascertain the point by taking its density, either by the specific gravity bottle or the hydrometer. Another method of ascertaining its density is by the *ammonia-meter* of J. J. Griffin of London, described and figured in *P. J.* (x. 413.) Although the U. S. Pharmacopœia states that "if stronger ammonia water be diluted with twice its volume of distilled water it should respond to the reactions and tests described under *Aqua Ammonia*," it will be usually found in practice that two volumes of water will be too much; in any event it would be safer to use a smaller quantity of water (one and a half volumes), and, if the mixture should not have the sp. gr. 0.958, it should be brought to that density by the addition either of the stronger solution or

of distilled water, as the case may require. *Great care should be exercised in opening bottles containing stronger ammonia water.* It is safer, if the ammonia water has been kept in a warm room, to cool it with ice before attempting to withdraw the stopper, as the liberated gas, when warm, frequently is forced out with extreme violence, and accidents which have resulted in injury to the sight of the operator are recorded.

Uses.—This solution is too strong for medicinal use in its unmixed state. Sufficiently diluted with spirit of camphor and rosemary, it has been much employed as a prompt and powerful rubefacient, vesicatory, or escharotic, in various *neuralgic, gouty, rheumatic, spasmodic, and inflammatory affections* in which strong and speedy counter-irritation is indicated. When mere rubefaction is desired, a mixture may be used composed of five fluidounces of the ammoniacal liquid and eight of the diluent liquid; and this will answer even for blistering or cauterizing, unless a very prompt effect be necessary. In the latter case a lotion may be resorted to consisting of five measures of the ammoniacal to three of the diluent liquid. These mixtures are applied by means of linen folded several times, or a thick piece of flannel saturated with the liniment. A convenient mode is to fill the wooden cover of a large pill or ointment box, an inch or two in diameter, with purified cotton, saturate this with the liquid, and press it upon the part. The ammonia is thus prevented from escaping, and a definite boundary given to the inflammation. The application will generally produce rubefaction in from one to eight minutes, vesication in from three to ten minutes, and a caustic effect in a somewhat longer time.

When a solution of ammonia of 25° (sp. gr. 0.905) is mixed with fatty matter, the mixture forms the *vesicating ammoniacal ointment* of Gondret. The revised formula of this ointment is as follows: Take of lard 32 parts, oil of sweet almond 2 parts. Melt them together by the *gentle* heat of a candle or lamp, and pour the melted mixture into a bottle with a wide mouth. Then add 17 parts of solution of ammonia of 25°, and mix with continued agitation until the whole is cold. The ointment must be preserved in a bottle with a ground stopper, and kept in a cool place. When well prepared, it vesicates in ten minutes. There may be danger of excessive irritation and inflammation of the nostrils, mouth, and air passages, from the inadvertent inhalation of the gas escaping from a bottle of the stronger ammonia water, when freshly opened; and serious consequences have occurred from this cause, or from the accidental breaking of the bottle. The best antidote, under these circumstances, is the inhalation of the vapors of vinegar or acetic acid.

Dose, three to six minims (0.2 to 0.4 Cc.), largely diluted.

AQUA AMYGDALÆ AMARÆ. U. S.

BITTER ALMOND WATER

(â'quâ a-mÿg'da-læ a-mă'ræ)

Eau d'Amandes amères, Fr.; Aqua Amygdalarum Amararum, P. G.; Bittermandelwasser, G.; Acqua distillata di mandorle amare, It.; Agua de almendras amargas, Sp.

* "Oil of Bitter Almond, one cubic centimeter [or 16 minims]; Distilled Water, nine hundred and ninety-nine cubic centimeters [or 33 fluidounces, 6 fluidrachms, 14 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Oil in the Distilled Water by agitation, and filter through a well-wetted filter." U. S.

Owing to the almost universal employment at this time (1906) of artificial oil of bitter almond (or benzaldehyde), which is free from hydrocyanic acid (such oil being much cheaper than that made from bitter almond), the bitter almond water of pharmacy cannot be relied upon as a medicinal agent, but is used mainly as a pleasant vehicle, but the requirements of the U. S. P. (8th Rev.) are that the oil of bitter almond shall contain not less than 85 per cent. of benzaldehyde, and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid, hence the use of benzaldehyde (see *Benzaldehydum*) is no longer permissible and care must be exercised not to prescribe a larger dose of the water to begin with than two teaspoonfuls (7.5 Cc.). Its principal use in this country is as a vehicle, many physicians prescribing it not for its medicinal virtues, but on account of its agreeable taste and powers of masking the taste of saline substances. The process for *Aqua amygdalarum amararum* of the German Pharmacopœia directs that 12 parts of bruised bitter almonds shall be expressed without heat, so as to remove as much fixed oil as possible; the press-cake is powdered, mixed thoroughly with 20 parts of water, and 9 parts distilled off into a receiver containing 3 parts of alcohol; the distillate is assayed to determine the percentage of hydrocyanic acid, and then diluted with a mixture of 1 part of alcohol and 3 parts of water, so that 1000 parts of the final product shall contain 1 part of hydrocyanic acid.

Under the name of *chloral hydrocyanate* a substance has been introduced for making cherry-laurel or bitter almond water extemporaneously. It occurs in white, translucent, rhombic prisms, soluble in water, alcohol, and ether. It has the odor of hydrocyanic acid and chloral, and is said to be a very stable compound. A solution of 6.5 grains of the salt in 1000 grains of distilled water corresponds with the official bitter almond water of the German Pharmacopœia, which is 1 to 1000. (*Merck's Bulletin*.)

For a method of determining the amount of hydrocyanic acid in bitter almond water, see *A. Pharm.*, Nov. 1878, 408; *A. J. P.*, Feb. 1879; *Zeit. Oest. Apoth. Ver.*, 1893, 45, 344, 387, 391.
Dose, one fluidrachm (3.75 Cc.).

AQUA ANETHI. Br.

DILL WATER

(ă'quă ā-ně'thī)

Eau d'Aneth, *Fr.*; Dillwasser, *G.*

"Dill Fruit, 1 pound (Imperial) or 500 grammes; Water, 2 gallons (Imp. meas.) or 10 litres. Distil one-half." *Br.*

This water, which is frequently prescribed in Great Britain, is occasionally used here; it closely resembles caraway water, over which it has no advantages. It is used only as a vehicle.

AQUA ANISI. U. S., Br.

ANISE WATER

(ă'quă ā-nī'sī)

Eau d'Anis, *Fr.*; Aniswasser, *G.*; Acqua distillata di anice, *It.*; Agua de anis, *Sp.*

* "Oil of Anise, two cubic centimeters [or 32 minims]; Purified Talc, fifteen grammes [or 231 grains]; Distilled Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Anise with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Anise Water is perfectly clear." *U. S.*

"Anise Fruit, 1 pound (Imperial) or 500 grammes; Water, 2 gallons (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Anise water is rarely made by distillation, although the product thus secured has a more delicate flavor than the U. S. preparation. It is used solely as a vehicle.

AQUA AURANTII FLORUM. U. S. (Br.)

ORANGE FLOWER WATER

(ă'quă āu-răn'tī-i flō'rūm)

"The orange-flower water of commerce, prepared by distillation from the flowers of the Bitter Orange tree, *Citrus Aurantium*, var. *Bigaradia*, *Hook. f.*, diluted, immediately before use, with twice its volume of Distilled Water." *Br.*

Aqua Aurantii Floris, *Br.* *Aqua Florum Naphæ*; Eau distillée (Hydrolat) de Fleurs d'Oranger, *Fr.* *Cod.*; Eau de Nappe, *Fr.*; Orangenblüthenwasser, *G.*; Acqua distillata di arancio, *It.*; Agua destilada de azahar, *Sp.*

"Stronger Orange Flower Water, Distilled Water, each, one volume. Mix them immediately before use." *U. S.*

The U. S. Pharmacopœia 1890 and the U. S. P. (8th Rev.) introduced "Stronger Orange Flower Water," providing for its dilution with

an equal volume of distilled water to make "orange flower water." This plan enables American pharmacists to employ the imported "triple" water, as it is known in commerce. This retains its fragrance longer than a weaker water; moreover, economy is effected through saving customs duty and freight, and a fresh, delicate water can be dispensed.

This preparation is also considered by the British Pharmacopœia as an object of importation. According to this authority, it is obtained from the flowers of the bitter orange tree; this is concurred in by our own official standard. In Italy and France, where it is largely made, the flowers of the bitter orange have long been preferred, as yielding the most fragrant product. It may be prepared in the most southern districts of our country from the fresh flowers; and these may be brought to the North for the same purpose, if previously incorporated with one-third or one-fourth of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. They may also be preserved by means of glycerin. Notwithstanding, however, the facility of preparing this water here, it is generally imported from the south of France, whence it usually comes in cans of tinned copper.

L. Malenfant observed that fresh orange flowers, mixed with cold water, yield, on distillation over the naked fire, a milky water, possessing a somewhat empyreumatic odor and a strong, somewhat acrid taste. Kept for twelve or eighteen months in glass vessels covered with parchment, it loses its empyreuma, and after filtering has an agreeable odor and taste. If the flowers be mixed with boiling water and immediately distilled, the water is limpid, and gradually separates some thick oil of a brownish color; the water has the odor and taste of the flowers, but complicated with an odor of the still, which it loses after long keeping; it seems to alter less rapidly than that obtained by the former process. Distilled by steam, a limpid water of a pure odor and taste is at once obtained, free from empyreuma; it may be at once used, and keeps better in the light than when obtained by the two former processes. (*A. J. P.*, June, 1874.) Hesse and Zeitschel (*J. Pr. Chem.*, 1901, 525) found by exhausting with ether the orange flower water obtained in the distillation of the orange blossoms that the quantity of oil dissolved in the water represented about one-third of the total amount of oil from the blossoms. A distilled water of the leaves is also prepared, and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (*J. P. C.*, 4e sér., iii. 249.) Orange flower water is used exclusively on account of its agreeable odor as a flavoring agent.

Orange flower water is stored in large glass vessels or carboys in cool cellars by the manu-

facturers in Grasse, France, care being taken not to stopper them tightly, but simply cover the orifice with a piece of paper or coarse cloth.

Nitric, sulphuric, or hydrochloric acid produces a red coloration with orange flower water, particularly if the water be shaken with ether to take up the oil, and the acid added to the ethereal solution. (*P. J.*, 1878, 248.) It is used as a vehicle, and to flavor syrups and elixirs.

Off. Prep.—Syrupus Amygdalæ, *U. S.*; Syrupus Aurantii Florum, *U. S.*; Syrupus Calcii Lactophosphatis, *U. S.*; Syrupus Lactucarii, *U. S.*

AQUA AURANTII FLORUM FORTIOR. U. S. (Br.)

STRONGER ORANGE FLOWER WATER
[Triple Orange Flower Water]

(â'quâ au-rân'ti-i flô'rûm fôr'ti-qr)

"Water saturated with the volatile oil of fresh orange flowers obtained as a by-product in the distillation of the oil of orange flowers. It should be kept in bottles loosely stoppered with a pledget of purified cotton, and in a dark place." *U. S.* The orange flower water of commerce is a saturated solution of the essential oil of the fresh flowers, and the British Pharmacopœia uses this in several preparations, terming it "Orange-flower water of commerce, undiluted." (See *Aqua Aurantii Florum*, p. 174.)

Orange flower water is nearly colorless, though often of a pale yellowish tint. "Stronger Orange Flower Water should be neutral to litmus paper, and have a strong odor of fresh orange flowers. It should be colorless and clear, or only faintly opalescent, not mucilaginous, and should give no reaction with hydrogen sulphide T.S. or ammonium sulphide T.S. (absence of metallic impurities)." *U. S.* From being kept in tinned copper cans, it sometimes contains metallic impurity, which is said to be chiefly lead carbonate, derived from the lead used as a solder in making the cans. The means of detecting metallic impurity are also mentioned under the general observations on distilled water. Much color, offensive odor, or mouldiness indicates impurity derived from the flowers in distillation.

Off. Prep.—Aqua Aurantii Florum, *U. S.*; Mistura Olei Ricini, *Br.*; Syrupus Aurantii Floris, *Br.*; Syrupus Calcii Lactophosphatis, *Br.*; Trochisci Acidi Tannici, *U. S.*; Trochisci Gambir, *U. S.*; Trochisci Kramerizæ, *U. S.*; Trochisci Santonini, *U. S.*

AQUA CAMPHORÆ. U. S., Br.

CAMPHOR WATER

(â'quâ câ'mphô-ræ)

Aqua Camphorata; Eau camphrée, *Fr. Cod.*; Kampherwasser, *G.*; Água alcanforada, *Sp.*

* "Camphor, eight grammes [or 123½ grains]; Alcohol, eight cubic centimeters [or 130 minims];

Purified Tale, fifteen grammes [or 231 grains]; Distilled Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluid-ounces, 6½ fluidrachms]. Dissolve the Camphor in the Alcohol, triturate the solution with the Purified Tale, and, after allowing the greater part of the Alcohol to evaporate spontaneously, continue the trituration with the Water, gradually added; then pour the mixture upon a well-wetted filter, and pass the filtrate through the filter repeatedly until the Camphor Water is perfectly clear." *U. S.*

"Camphor, 70 grains (Imperial) or 5 grammes; Alcohol (90 per cent.), a sufficient quantity; Distilled Water, 1 gallon (Imp. meas.) or 5 litres. Dissolve the Camphor in a sufficient quantity of the Alcohol to form half a fluid ounce (or fifteen cubic centimetres) of the solution; add this in successive portions to the Distilled Water, shaking after each addition; finally agitate occasionally until all the Camphor is dissolved." *Br.*

In both of these processes the sole object is to effect a solution; water is capable of dissolving but a very small proportion of camphor, but the quantity varies with the method employed. The present official process is an improvement on former methods, for it undoubtedly secures a saturated solution easily. Magnesium carbonate is to be preferred to purified tale as a distributing agent were it not for the fact that it is slightly soluble in water. The present British process is more efficient than the old formula, a definite quantity of camphor being dissolved in a small quantity of alcohol and this solution gradually added to the proper quantity of water; it is questionable, however, whether it would not be advantageous to use an insoluble powder to aid in the solution and thus obtain quickly a clear liquid, as the water made by the British process is sometimes cloudy. In the former British process no trouble was taken even to comminute the camphor, or to shake it with the water, which was thus allowed to take up what it might be disposed to do by contact with the camphor contained in a bag. The solution thus effected was extremely feeble, containing probably less than one part in a thousand; this proportion, according to Berzelius, is taken up by water when triturated with camphor. It was, besides, of uncertain strength, varying with the size of the fragments of camphor. J. C. Pooley found that 120 grains of camphor, treated according to the former British official directions, gave, when cut into 4 pieces, 6 grains to half a gallon of water, but in 20 pieces gave 20 grains, or about one part to 1750 of water. (*P. J.*, 2d ser., vii. 162.) Wm. B. Addington proposed to add to the camphor just enough alcohol to dissolve it, and triturate the liquor with magnesia, during which process he affirmed that the alcohol evaporated (*A. J. P.*, xlv. 209); and F. T. Hartzell substituted ether for alcohol, a few drops of which enabled him to bring the camphor to an impalpable powder. (*Ibid.*,

xlvi. 233.) The camphor is separated from its aqueous solution by a solution of pure potassium hydroxide, and, according to Paris, by magnesium sulphate and several other salts. J. Murray proposes a solution of camphor and magnesium bicarbonate, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is too feeble a preparation for use when a decided effect is desired; it is, however, an excellent vehicle for the administration of more active substances.

Dose, half to one fluidounce (15 to 30 Cc.), repeated every one or two hours.

AQUA CARUI. Br.

CARAWAY WATER

(ă'quă cār'ū-i)

Aqua Carui; Eau Distillée de Carvi, *Fr.*; Kümmelwasser, *G.*

"Caraway Fruit, 1 pound (Imperial) or 500 grammes; Water, 2 gallons (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Distilled Caraway Water has the flavor of the fruit or seeds, but is seldom used in the United States. The water made from the volatile oil (15 minims in a pint), in the same manner as is cinnamon water, is largely employed. It is used only as a vehicle.

AQUA CHLOROFORMI. U. S., Br.

CHLOROFORM WATER

(ă'quă chlō-rō-fōr'mī)

Eau de Chloroforme, *Fr.*; Chloroformwasser, *G.*; Agua chloroformada, *Sp.*

"Chloroform, Distilled Water, each, a sufficient quantity. Add enough Chloroform to a convenient quantity of Distilled Water, contained in a dark amber-colored bottle, to maintain a slight excess of the former, after the contents have been repeatedly and thoroughly agitated. When Chloroform Water is required for use, pour off the needed quantity of the solution, refill the bottle with Distilled Water and saturate it by thorough agitation, taking care that there be always an excess of Chloroform present." *U. S.* "Chloroform, 30 minims (Imperial measure) or 2.5 cubic centimetres; Distilled Water, sufficient to produce 25 fluid ounces (Imp. meas.) or 1000 cubic centimetres. Shake them together until the Chloroform is dissolved." *Br.*

The water should be fully saturated, in which case it should contain one-half per cent. of chloroform. The British preparation contains half the proportion of Chloroform present in the corresponding preparation of the British Pharmacopœia (1885). Chloroform water has been proved to be an excellent vehicle for administering active remedies, and, owing to its antiseptic properties, mixtures having it for a basis resist decomposition longer than those made with ordinary water.

Dose, one-half to two fluidounces (15 to 60 Cc.).

AQUA CINNAMOMI. U. S., Br.

CINNAMON WATER

(ă'quă cīn-nā-mō'mī)

Eau distillée de Cannelle, *Fr. Cod.*; Aqua Cinnamomi, *P. G.*; Zimmtwasser, *G.*; Acqua distillata di canella, *It.*; Agua destilada de canela, *Sp.*

* "Oil of Cinnamon, two cubic centimeters [or 32 minims]; Purified Tale, fifteen grammes [or 231 grains]; Distilled Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Cinnamon with the Purified Tale, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Cinnamon Water is perfectly clear." *U. S.*

"Cinnamon Bark, bruised, 1 pound (Imperial) or 500 grammes; Water, 2 gallons (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Of these processes, that of the *U. S. Pharmacopœia* is the easier, though the second, the British, may yield a sweeter product. On standing, cinnamon water, made from oil of Ceylon cinnamon, is apt to precipitate, owing to the gradual oxidation and formation of cinnamic acid, which is comparatively insoluble in water; this can be prevented, according to E. Backhaus, by passing a stream of carbon dioxide through the fresh water for a few minutes. We have never seen the precipitation successfully prevented, notwithstanding the application of numerous so-called preventatives; these usually delay the precipitation, but in a few weeks' time the cloudiness due to the formation of minute crystals of cinnamic acid invariably appears. When oil of cassia is used as directed in the *U. S. P.* (8th Rev.) process precipitation rarely occurs. (See *Oleum Cinnamomi*.) E. Holmes recommends glycerin as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect the solution of a drop of the oil in a fluidounce of water.

Cinnamon water is much used as a vehicle for other less agreeable medicines, but should be given cautiously in inflammatory affections. For ordinary purposes the *U. S.* preparation is sufficiently strong when diluted with an equal measure of water.

Off. Prep.—Infusum Digitalis, *U. S.*; Mistura Cretæ, *U. S., Br.*; Mistura Guaiaci, *Br.*; Mistura Olei Ricini, *Br.*; Mistura Spiritus Vini Gallici, *Br.*; Syrupus Aromaticus, *Br.*; Syrupus Cascariæ Aromaticus, *Br.*

AQUA CREOSOTI. U. S.

CREOSOTE WATER

(ă'quă crē-ō-sō'tī)

Creasote Water; Eau créosotée, *Fr.*; Kreosotwasser, *G.*

* "Creosote, ten cubic centimeters [or 162 minims]; Distilled Water, nine hundred and

ninety cubic centimeters [or 33 fluidounces, 228 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Agitate the Creosote vigorously with the Distilled Water, and filter through a well-wetted filter. Creosote Water should be freshly prepared when dispensed." *U. S.*

This preparation contains 1 per cent., or about 4.8 minims, of creosote in each fluidounce, and affords a convenient method of administering that medicine. It is about the same strength as that formerly official. It may also be used with advantage as a gargle, a lotion, or mixed with cataplasms, to correct *fetor*, and gently stimulate *indolent surfaces*.

Dose, from one to four fluidrachms (3.75 to 15 Cc.).

AQUA DESTILLATA. U. S., Br.

DISTILLED WATER

(ä'qua dës-tijl-lä'tä)

H₂O = 17.88

"Prepared by distillation from good natural potable water." *Br.*

Eau distillée, *Fr. Cod.*; Aqua distillata, *P. G.*; Destillirtes Wasser, *G.*; Acqua distillata, *It.*; Agua destilada, *Sp.*

* "Water, *one thousand volumes* [or 33 fluidounces, 6½ fluidrachms], to make *eight hundred volumes* [or about 27 fluidounces]. Distil the Water from a suitable apparatus provided with a block-tin or glass condenser. Collect the first *one hundred volumes* [or 3½ fluidounces], and reject this portion. Then collect *eight hundred volumes* [or 27 fluidounces] and keep the Distilled Water in glass-stoppered bottles, which have been rinsed with hot distilled water immediately before being filled." *U. S.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above process for its distillation. It is best to reject the first portion which comes over, as this may contain carbon dioxide and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of block tin or glass. Brande states that distilled water often derives from the still a foreign flavor, which it is difficult to avoid. He therefore recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of steaming it out, before it is used, the worm-tub having been previously emptied. J. N. Hurty prefers well water as the source of distilled water, and that it be boiled before collecting the distillate, to get rid of ammonia, and, to prevent access and growth

of spores, that the water be heated to boiling before introducing it into the container, and that it be drawn off by a siphon tube reaching to the bottom of the vessel, the mouth of which is loosely stoppered with cotton. (*West. Drug.*, 1887, p. 4.) Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity, as water distilled from metallic alembics with the head and worm of this metal has a peculiar odor which it retains for some time. Ordinary distilled water invariably contains ammonia, as may be proved by adding a few drops of Nessler's reagent. (See PART III.) In order to free distilled water from volatile nitrogenous bodies, it is necessary to redistil it after it has been placed in contact with potassium permanganate and potassium hydroxide. After about one-twentieth of the water has come over, the distillate is usually free from ammonia, and leaves no residue on evaporation. If traces of ammonia remain, acid potassium sulphate is added, and it is redistilled. (*Stas.*) Distilled water when kept long in glass vessels dissolves a minute quantity of the glass and the official test permitting 0.075 Gm. of residue in 1000 Cc. after evaporation to dryness, was inserted to avoid unnecessary severity in the test for a solvent used for pharmaceutical purposes.

Properties.—Distilled water, as usually obtained, has a rapid and disagreeable taste, and is not perfectly pure, water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change with hydrogen sulphide, or on the addition of tincture of soap, lead subacetate, barium chloride, ammonium oxalate, silver nitrate, or lime water. "A colorless, limpid liquid, without odor or taste, perfectly neutral to litmus paper. Distilled Water should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121), nor should the slightest turbidity result upon the addition to separate portions, of barium chloride T.S. (*sulphates*), silver nitrate T.S. (*chlorides*), ammonium oxalate T.S. (*calcium*); nor should its transparency be affected when mixed with twice its volume of calcium hydroxide T.S. (absence of *carbonic acid*). It should give no reaction for nitrates, nitrites, or ammonia when tested as described under *Aqua*. When 1000 Cc. of Distilled Water are evaporated on a water-bath to dryness, not more than 0.075 Gm. of *residue* should remain. On heating to boiling 100 Cc. of Distilled Water, acidulated with 10 Cc. of diluted sulphuric acid, and subsequently adding 0.1 Cc. of tenth-normal potassium permanganate V.S., the color of the liquid should not be completely destroyed by boiling for ten minutes, nor should it wholly disappear if the vessel be afterwards set aside in a dark place, covered, for ten hours (absence of *organic* or *other oxidizable substances*)." *U. S.* It is needlessly

employed in some formulas, but is essential in others. The British Pharmacopœia requires distilled water to be "Colorless, tasteless, and odorless. 25 cubic centimetres evaporated in a platinum capsule should leave at most a scarcely visible residue (absence of dissolved solids). It should yield no reaction with the tests for the various metals, chlorides, nitrates, nitrites, or sulphates. It should not affect *litmus paper* (absence of acid or alkaline matter). The liquid obtained on boiling 100 cubic centimetres for three minutes with 1.0 cubic centimetre of *diluted sulphuric acid* and 0.1 cubic centimetre of a mixture of one part of *solution of potassium permanganate* and two parts of *water*, should retain its color for one hour (absence of more than traces of organic matter). 100 cubic centimetres mixed with 2 cubic centimetres of *solution of potassium-mercuric iodide*, should not afford a yellow tint more intense than that given by 0.25 cubic centimetre of *solution of ammonium chloride* (Nessler's) diluted with 50,000 cubic centimetres of ammonia-free water when viewed, under similar conditions, in a glass tube having a diameter of one inch (25 millimetres) (absence of more than 0.005 part of ammonia per million parts)." *Br.* As a rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, silver nitrate, barium and calcium chlorides, lead acetate and subacetate, potassium permanganate, iron and zinc sulphates, quinine sulphate, morphine sulphate, hydrochloride, and acetate, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the official diluted acids, for absorbing gaseous ammonia, and for forming nearly all the official aqueous solutions.

AQUA FŒNICULI. U. S., Br.

FENNEL WATER

(ă'quă fœ-nîc'û-li)

Eau de Fenouil, *Fr.*; Aqua Fœniculi, *P. G.*; Fenchelwasser, *G.*; Acqua distillata di finocchio, *It.*; Agua de hinojo, *Sp.*

* "Oil of Fennel, *two cubic centimetres* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand cubic centimetres* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Fennel with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Fennel Water is perfectly clear." *U. S.*

"Fennel Fruit, *1 pound* (Imperial) or 500 grammes; Water, *2 gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Fennel water is a pleasant vehicle for other medicines, and useful when a mild aromatic is

indicated. The process of the British Pharmacopœia, although more troublesome, furnishes a more delicate and agreeable water than does that of the U. S. Pharmacopœia. Used as a vehicle.

AQUA HAMAMELIDIS. U. S. (Br.)

HAMAMELIS WATER

(ă'quă hăm-ă-měl'î-dis)

Liquor Hamamelidis, Br.; Solution of Hamamelis, Witchhazel water, Witchhazel extract; Eau distillée de hamamelis, *Fr.*; Hamameliswasser, *G.*

* "Hamamelis Bark, *ten thousand grammes* [or 22 pounds av.]; Water, *twenty thousand cubic centimeters* [or 42 pints]; Alcohol, *fifteen hundred cubic centimeters* [or 51 fluidounces]; to make *ten thousand cubic centimeters* [or 21 pints]. Macerate the Hamamelis Bark in the Water during twenty-four hours, then distil until *eighty-five hundred cubic centimeters* [or 17 pints, 15 fluidounces] of distillate are obtained, add the Alcohol, and mix thoroughly." *U. S.* "Fresh Hamamelis Leaves, *50 ounces* (Imperial) or 1000 grammes; Water, *100 fl. ounces* (Imp. meas.) or 2000 cubic centimetres; Alcohol (90 per cent.), *10 fl. ounces* (Imp. meas.) or 200 cubic centimetres. Macerate in a still for twenty-four hours; then distil one-half." *Br.*

Hamamelis Water or, as it is popularly called, "Distilled Extract of Witchhazel," has been found on the market with very little alcohol in it, formaldehyde being used as a preservative; the official test is as follows: "If 1 Cc. of Hamamelis Water be added to 5 Cc. of sulphuric acid containing a little salicylic acid in solution, no red color should appear (absence of *formaldehyde*)." *U. S.*

Uses.—This water was probably introduced into the British Pharmacopœia and U. S. Pharmacopœia (8th Rev.) on account of the large demand for it which has grown out of the wide advertisements of a certain proprietary medicine, and the universally recognized need in American families for an embrocation which appeals to the psychic influence of faith. As the tannic acid of hamamelis bark does not come over into the distillate the water is therapeutically a mixture of water and alcohol. (See *Hamamelidis Cortex*.)

AQUA HYDROGENII DIOXIDI.

U. S. (Br.)

SOLUTION OF HYDROGEN DIOXIDE

[Solution of Hydrogen Peroxide]

(ă'quă hÿ-drŏ-gĕn'î dî-ŏx'î-di)

"A slightly acid, aqueous solution of Hydrogen Dioxide [$H_2O_2 = 33.76$], which should contain, when freshly prepared, about 3 percent., by weight, of absolute Hydrogen Dioxide, corresponding to about 10 volumes of available oxygen. It should be kept in a cool place. Upon removing the stopper from the bottle

not more than a slight pressure should be observed." *U. S.* "An aqueous solution of hydrogen peroxide, H_2O_2 , prepared by the interaction of water, barium peroxide, and a dilute mineral acid, at a temperature below 50°F . (10°C)." *Br.*

Liquor Hydrogenii Peroxidi, *Br.*, Solution of Hydrogen Peroxide; Oxygenized Water, Oxygen Hydrate; Peroxide d'hydrogène; Soluté officinal d'eau oxygénée au dixième, *Fr. Cod.*; Wasserstoffhyperoxyd, Wasserstoffhyperoxydlösung, *G.*; Acqua ossigenata, *It.*; Agua oxigenada, *Sp.*

The extended use of this preparation, which was discovered by Thenard in 1818, has earned for it a place in the *U. S.* and British Pharmacopœias. It consists of water in which, by the presenting to it of oxygen in a nascent state, an additional atom of this element has combined with the hydrogen, forming the dioxide, $(\text{HO})_2$, or H_2O_2 .

The *U. S. P.* 1890 process (see *U. S. D.*, 18th edition, p. 214) consisted in the decomposition of barium dioxide by phosphoric acid, barium phosphate being thrown down as a precipitate, hydrogen dioxide being found dissolved in the supernatant aqueous liquid; the barium phosphate is filtered out, and any trace of barium salt is finally removed by the cautious addition of sulphuric acid, which precipitates it as insoluble barium sulphate; the very fine precipitate which usually passes through the pores of filter paper is caught and held on the filter by the starch, and the clear solution may be adjusted to contain 3 per cent., *by weight*, of absolute hydrogen dioxide by the assay, which follows.

Assay.—"Dilute 10 Cc. of the Solution with sufficient distilled water to measure 100 Cc. Transfer 16.9 Cc. of this liquid (containing 1.69 Cc. of the solution) to a beaker, add 5 Cc. of diluted sulphuric acid, and then, from a burette, slowly add, with constant stirring, tenth-normal potassium permanganate V.S. until the liquid just retains a faint pink tint. Each Cc. of tenth-normal potassium permanganate V.S. consumed corresponds to 0.1 percent. of absolute Hydrogen Dioxide, or 0.329 volumes of oxygen. If the Solution be of full strength, 30 Cc. of tenth-normal potassium permanganate V.S. will be required." *U. S.*

For another method of preparing this Solution, see *U. S. D.*, sixteenth edition, page 1887. According to Crismer, a pure solution may be made by dissolving barium peroxide in a slight excess of diluted hydrochloric acid (sp. gr. 1.10), and shaking the solution with an equal volume of ether. The ethereal layer is separated and shaken with a little water, which will take up most of the hydrogen peroxide, after the separation of which the ether is again shaken with the above separated solution of barium peroxide, and then with water as before. These operations are repeated five or six times. It is possible in this way to obtain solutions containing from 0.8 to 0.9 per cent. of the peroxide, which are perfectly neutral and free from foreign substances. (*Bull. Soc. Chim.*, 1891, 24.)

Horlin (*Zeit. angew. Chem.*, 1902, 600) prepares the solution by adding at a low temperature with caution, sodium dioxide to a solution of hydrofluoric acid; hydrogen dioxide and sodium fluoride are produced, the solution is treated with aluminum fluoride, which results in producing the insoluble double fluoride of aluminum and sodium, which separates out. The official Solution is strong enough for most practical uses, for, although it can readily be made stronger, the difficulties of preserving it largely increase with its increased strength, and hence the Committee of Revision wisely fixed the standard at *ten volumes of available oxygen*. The British Pharmacopœia requires that the Solution shall indicate a yield of from *nine to eleven volumes* of oxygen when tested by the nitrometer test. (See page 180.)

Properties.—Solution of hydrogen dioxide was prepared by Regnault in a nearly pure state. As thus procured, it is a colorless liquid of a fluid consistence, of the sp. gr. 1.452, remaining liquid at zero, beginning to give out oxygen when heated above 15.5°C . (60°F .), and at a higher heat rapidly and sometimes explosively resolved into water and oxygen. But when diluted with water, with which it unites in all proportions, it is not decomposed under 37.7°C . (100°F .). It may be evaporated *in vacuo* at a gradually increasing temperature, a nearly pure hydrogen dioxide coming over at about 84°C . Wolfenstein states that he has prepared, after repeated fractioning, hydrogen peroxide (99.1 per cent.). (See *Ber. d. Chem. Ges.*, 1894, 3307. See also Schiloff's process, *Chem. News*, 1896, 38.) Crystallized hydrogen dioxide has been made by W. Staedel by applying a freezing mixture to a very strong solution of the dioxide and collecting the separated columnar crystals; it is a very active body, being decomposed with explosive violence on coming in contact with manganese dioxide (*Ph. Centralth.*, 1902, 546). The great facility with which it parts with oxygen renders it a powerful oxidizer; and the simple contact with various substances, as platinum, gold and silver, causes it to be resolved into oxygen and water. On the contrary, certain other substances, even though ordinarily evincing a strong affinity for oxygen, as phosphorus, for example, are unaffected by it, and there are a number of bodies which have the property not only of being unaffected by it, but of restraining its oxidizing influence on other bodies, while some salts, like silver oxide, are actually reduced by it. Traces of impurities modify the stability of hydrogen dioxide; acids increase, alkalies decrease, its stability. Some manufacturers add a certain proportion of oxalic acid to the solution of hydrogen dioxide to raise the apparent value of the product, as shown by the permanganate assay; for a method of detecting this fraud see a paper by G. Arth (*D. C.*, 1902, p. 141).

The official Solution is described as "a colorless liquid, without odor, slightly acidulous to the taste, and producing a peculiar sensation

and soapy froth in the mouth; liable to deteriorate upon keeping or protracted agitation. If the stopper in the bottle be replaced by a pledget of cotton, deterioration is retarded. When exposed to the air at the ordinary temperature, or when heated on a water-bath at a temperature not exceeding 60° C. (140° F.), the solution loses chiefly water. When rapidly heated, it frequently decomposes suddenly. On adding to 10 Cc. of water, in a test-tube, 1 drop of potassium chromate T.S., then 10 drops of diluted sulphuric acid, and pouring a few Cc. of ether on top, the subsequent addition of a few drops of Solution of Hydrogen Dioxide, even when considerably diluted, will cause a blue color to appear at the zone of contact of the two liquids. After shaking, the ether-layer will separate with a blue color. If to 25 Cc. of the Solution, 5 Cc. of tenth-normal potassium hydroxide V.S. be added, and the mixture be evaporated to about 10 Cc., and 3 drops of phenolphthalein T.S. added, not less than 2.5 Cc. of tenth-normal sulphuric acid V.S. should be required to discharge the red color of the solution after continued boiling (limit of *free acids*). If 20 Cc. of the Solution be evaporated to dryness upon a water-bath, and the drying completed at 120° C. (248° F.), not more than 0.03 Gm. of solid residue should remain (limit of *total solids*). If to 1 Cc. of the Solution, 1 Cc. of ammonia water be added, and the liquid evaporated to dryness upon a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see Part III, Test No. 17). If to 1 Cc. of the Solution, 1 Cc. of ammonia water be added and the mixture be evaporated to dryness upon a water-bath, the residue, when dissolved in 10 Cc. of distilled water containing 1 Cc. of diluted hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see Part III, Test No. 121). On evaporating to dryness, upon a water-bath, 50 Cc. of the Solution, previously rendered alkaline by sodium hydroxide T.S., transferring the dry residue to a watch-glass, moistening it with sulphuric acid, and setting the glass in a moderately warm place for a few hours, the surface of the glass, after being washed, should exhibit no sign of corrosion (absence of *hydrofluoric acid*). The addition of a few drops of diluted sulphuric acid to 10 Cc. of the Solution should produce no turbidity or precipitate (absence of *barium*).” *U. S.* “On adding a few drops to 8 or 10 cubic centimetres of water containing a drop of solution of potassium chromate, 10 drops of diluted sulphuric acid, and 2 or 3 cubic centimetres of ether, a blue layer will appear between the ethereal and aqueous liquids, and, after agitation, the ether will also become blue. 1 volume, treated in a brine-charged nitrometer with 10 or 12 times its bulk of a mixture of 1 volume of sulphuric acid, 2 volumes of a 5 per cent. solution of potassium permanganate, and 7 volumes of water, should afford, at normal temperature and pressure, not less than 18 and not more than

22 volumes of oxygen, indicating a yield of 9 to 11 volumes from the Solution of Hydrogen Peroxide. It should give no characteristic reaction with the tests for barium. Evaporated to dryness on a water-bath, not more than 0.5 per cent. of solid residue should remain.” *Br. Charles Rice* suggests improvements in the method of assay which are practical (see *Am. Drug.*, 1892, 30). *F. X. Moerk* has proposed a rapid and effective method of assaying this solution (see *A. J. P.*, 1893, 65); *J. F. Brown* confirmed the value of Moerk's method (*P. J.*, 1896, 271). *Solution of hydrogen dioxide should be kept in a cool place, and not too tightly stoppered.* (A plug of absorbent cotton is often used.) Neglect of these precautions, particularly in hot weather, will be likely to result in an explosion and fracture of the bottle containing it, due to a brisk evolution of oxygen in a confined space, on account of the increased temperature.

Uses.—Many years ago *B. W. Richardson* of London, pointed out that hydrogen dioxide is a powerful physiological agent, which, when brought in contact with most animal tissues, or with sugar or starch, acts as an oxidizing agent. It does not, however, seem to be of value for affecting the general system, as it was found in the experiments of *H. C. Wood* to coagulate blood so rapidly when put into the blood-vessel that it does not seem possible for it to find entrance into the blood, and the former allegations of its possessing specific power in infective fevers have been completely disproven. It is useful only as a local remedy.

When hydrogen dioxide is brought in contact with the mucous membrane or ulcerated surfaces, albuminous coagulation is immediate, with the formation of a white coating and a rapid evolution of gas. It is a powerful antiseptic. The conclusions of *Pane (L. M. R., Jan. 1891)* were that—1. Hydrogen dioxide in a solution of 1 to 100 has an energetic disinfecting power. 2. The solution 1 to 1000 is a weak antiseptic, and inferior to the corresponding solution of corrosive sublimate. The solution of H_2O_2 , in nutritive substances (1 to 352), not only impedes the development but after some days kills the spores of the bacillus of charbon. According to *Sternberg*, however, the bactericidal power of H_2O_2 has been greatly overestimated. He asserts that the results following the use of commercial solutions are due more to the sulphuric acid that they contain than to the dioxide. *Gifford (N. Y. M. R., 1888)* found that a neutral solution containing 15 per cent. by volume of H_2O_2 killed the anthrax spores in 5 minutes and pus cocci in one minute. The same solution diluted with 4 parts of water did not kill pus cocci after thirty minutes exposure. The presence of large amounts of organic matter so rapidly reduces the peroxide that its disinfectant power is much lessened.

On account of its oxidizing properties, it is a powerful deodorant, rapidly destroying hydro-

gen sulphide and similar gases. When hydrogen dioxide is brought in contact with pus, rapid change occurs, with evolution of oxygen gas, and Pane found under the microscope that so soon as charged with gas the corpuscles become granular, lose their form, and break up into detritus. Marshall, however, believes that the evolved gas is carbon dioxide.

Its liquid form makes it especially adapted for infected wounds, putrid cavities and abscesses, which it will thoroughly cleanse. It cannot, however, take the place of such antiseptics as mercuric chloride, because its influence is so immediate and so fugacious. As a preventive antiseptic it is of little value. For disinfecting the hands and instruments of the surgeon it has the great advantage of immediate and powerful action, and of not staining the hands or clothing. By some surgeons it is said not to affect the instruments.

As a local application in specific inflammations of the mucous membrane hydrogen dioxide is of greatest value. In scarlet fever and diphtheria the official solution may be applied by mop to the pharynx, often with extraordinarily good results. Diluted one-half, it may be injected into the nasal cavities when they are affected. Injection of a solution of from 20 per cent. to full strength has received commendation in the treatment of gonorrhœa and chancre. The official solution may be used as a local styptic. It is not probable that hydrogen dioxide can produce general poisoning, but when employed too freely upon large internal sensitive surfaces it appears to be capable of causing death by the shock produced through the intense local irritation. Thus, Pane has shown that rabbits may be killed by injecting a strong solution into the peritoneal cavity. In a case reported by Laach (*L. L.*, Oct. 1886), six injections into the pleural cavity, each containing 0.8 cubic centimeter of a 3 per cent. solution of hydrogen dioxide, were administered, but at the seventh the patient complained of faintness, the pulse failed, respiration became oppressed, and death occurred in ten minutes. As a local application to mucous membranes, the official solution should be used; the stronger solutions are sometimes too irritating.

Solution of hydrogen dioxide has come to be a common commercial preparation in 10 or 15 per cent. aqueous solutions. It is used for the purpose of cleaning and bleaching old and stained engravings and oil paintings. The dioxide has also been used as an auricome for bleaching dark colored hair. It is employed, moreover, in increasing degree in the textile industries for bleaching. Lunge has proposed its use in the ready valuation of chlorinated lime or bleaching powder, which is decomposed by it with the simultaneous liberation of oxygen from both substances in equal amount.

Dose, as given in the U. S. Pharmacopœia, one fluidrachm (3.75 Cc.).

AQUA LAUROCERASI. Br.

CHERRY-LAUREL WATER

(â'quâ lâurô-cêr'a-si)

Eau distillée de Laurier-cerise, *Fr. Cod.*; Kirschloerbeerwasser, *G.*; Agua destilada de laurel-cerezo, *Sp.*

"Fresh Cherry-Laurel Leaves, 1 pound (Imperial) or 320 grammes; Water, 2½ pints (Imp. meas.) or 1000 cubic centimetres. Place the crushed Cherry-Laurel Leaves with the water in a retort; distil one pint (or four hundred cubic centimetres) of liquid; shake the product; filter, if necessary; adjust the strength of the finished product either by adding hydrocyanic acid or by diluting the distillate with Distilled Water, so that, when tested as described under 'Acidum Hydrocyanicum Dilutum,' it shall contain one-tenth per cent. of hydrocyanic acid, HCN." *Br.*

It is greatly to be regretted that this uncertain, dangerous, and troublesome preparation should retain its place in European pharmacopœias, inasmuch as it could easily be replaced by a flavored water containing a definite amount of a soluble cyanide.

As the cherry-laurel is little cultivated in the United States, the water is not official; but from several experiments by William Procter there is little or no room to doubt that a preparation identical in its effects might be made from the leaves of our common wild cherry, *Prunus serotina*. The imported cherry-laurel water, as found in commerce, is generally impaired by age, and not to be relied on.

A. Ripping of Rotterdam, proposes to make an artificial cherry-laurel water by adding 6 grammes of oil of cherry-laurel and 4.5 grammes of potassium cyanide to a half-litre of water, and distilling the mixture in a tubulated retort, a current of carbonic acid gas being passed through it at the same time. The distillate is afterwards diluted with distilled water so as to contain one-tenth per cent. of hydrocyanic acid. (*A. Pharm.*, 1876, pp. 526-531.)

Cherry-laurel leaves contain 65 per cent. of water, sufficient to provoke the reactions which result in the formation of a volatile oil and hydrocyanic acid. Water is very prone to hasten the conversion of the volatile oil into benzoic acid by oxidation, and it has been found by C. Umney (*P. J.*, x. 467) and by Moore (*Ibid.*, 604) that the water distilled without previous maceration is somewhat stronger in hydrocyanic acid and decidedly stronger in oil (Umney) than the official product. The strength of official cherry-laurel water is so uncertain as to render it ineligible. It ought to be a powerful preparation, about one-twentieth the strength of the official hydrocyanic acid (*Br. Ph.*), and yet in commerce it varies as 53 to 100 (Umney). The difference depends upon the age of the preparation, the mode of preparing, and the time of year at which the leaves are gathered. Garot (*Ann. Thér.*, 1843, 45) has found that the leaves yield only half as much in July as in

April. C. Umney obtained 1.26 grains of acid in 1000 grains in March, in July 1.08 grains, and in November 0.64 grains. (*P. J.*, x. 468.) Moore, in an elaborate series of experiments, obtained the largest product in July of one year and in October of the next. Leger (*Ibid.*, June, 1873) has found the maximum percentage in July, and also that different leaves taken from the same bush on the same day vary enormously, young leaves being much richer than the old ones. The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by Deschamps that if a drop of sulphuric acid be added to a pint of the preparation it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. Lepage found that, preserved in full and perfectly air tight bottles, both this and bitter almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*J. P. C.*, xvi. 346.) In view of the uncertain strength of the water as obtained from the leaves, it was proposed in France, in reference to the Codex then in preparation, to fix upon a definite proportion of hydrocyanic acid; and the percentage generally adopted was from 0.04 to 0.05. For Denigés's method of assaying the water, see *Proc. A. Ph. A.*, 1894, 556.

Uses.—Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its properties with a diluted solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the more definite preparation of the acid now in use. Its fraudulent use in Paris in the preparation of a cordial, in imitation of the genuine cherry cordial, made by fermentation and distillation, and like it called "*kirsch*," has been the subject of no little reprobation. (*J. P. C.*, 4e sér., i. 33, 1865.)

Dose, thirty minims to a fluidrachm (1.8 to 3.75 Ce.).

AQUA MENTHÆ PIPERITÆ.

U. S., Br.

PEPPERMINT WATER

(ā'quā mēn'thæ pīp-ē-rī'tæ)

Eau distillée de Menthe poivrée, *Fr. Cod.*; Aqua Menthae Piperitæ, *P. G.*; Pfefferminzwasser, *G.*; Acqua distillata di menta piperita, *It.*; Agua destilada de menta piperita, *Sp.*

* "Oil of Peppermint, *two cubic centimeters* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Peppermint with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Peppermint Water is perfectly clear." *U. S.*

"Oil of Peppermint, 77 *minims* (Imperial measure) or 10 cubic centimetres; Water, 1½ *gallons* (Imp. meas.) or 15 litres. Distil two-thirds." *Br.* Used as a vehicle.

AQUA MENTHÆ VIRIDIS. U. S., Br.

SPEARMINT WATER

(ā'quā mēn'thæ vir'ī-dis)

Eau de Menthe verte, *Fr.*; Römisch-Minzwasser, *G.*; Agua de yerba buena, *Sp.*

* "Oil of Spearmint, *two cubic centimeters* [or 32 minims]; Purified Talc, *fifteen grammes* [or 231 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Oil of Spearmint with the Purified Talc, add the Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Spearmint Water is perfectly clear." *U. S.*

"Oil of Spearmint, 77 *minims* (Imperial measure) or 10 cubic centimetres; Water, 1½ *gallons* (Imp. meas.) or 15 litres. Distil two-thirds." *Br.*

There would seem to be no good reason for distilling the mint waters from their respective volatile oils, as directed in the British processes. If the fresh plants were available, a good source for a distilled water could be provided; but if a volatile oil must be used with its uncertainty of freshness always present, the quicker process of the U. S. P. is greatly preferable.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. Peppermint water is generally thought to have a more agreeable flavor than that of spearmint, but some prefer the latter. Their effects are the same. Used as a vehicle.

AQUA PIMENTÆ. Br.

PIMENTO WATER

(ā'quā pī-mēn'tæ)

Eau de piment de la Jamaïque, *Fr.*; Nelkenpfefferwasser, *G.*

"Pimento, bruised, 8 *ounces* (Imperial) or 250 grammes; Water, 2 *gallons* (Imp. meas.) or 10 litres. Distil one-half." *Br.*

Pimento water is an agreeable aromatic water, used as a vehicle.

AQUA ROSÆ. U. S., Br.

ROSE WATER

(ā'quā rō'sæ)

Eau distillée de Rose, *Fr. Cod.*; Aqua Rosæ, *P. G.*; Rosenwasser, *G.*; Acqua distillata di Rose, *It.*; Agua destilada de rosas, *Sp.*

* "Stronger Rose Water, Distilled Water, each, *one volume* [or 1 pint]. Mix them immediately before use." *U. S.* "The rose water of commerce,¹ prepared by distillation from the flowers of *Rosa damascena*, *Linn.*, diluted, immediately before use, with twice its volume of Distilled Water." *Br.*

The British Pharmacopœia of 1898 abandoned the former process of distilling the leaves and followed the method adopted by the *U. S. Pharmacopœia* of diluting the so-called triple rose water of commerce with distilled water. This, however, does not make rose water identical in strength in these authorities, the *U. S.* preparation being about 17 per cent. the stronger.

Although domestic rose water of fair quality may be made by distilling fresh rose petals, it does not possess the strength or delicacy of the by-product obtained from abroad, as officially described under *Aqua Rosæ Fortior*; hence the above process of diluting this stronger rose water. The process of distilling the fresh petals of the hundred-leaved rose is sometimes practised. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odor, and afford a water equally fragrant with that prepared from the fresh flowers. Indeed, Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and keeps its odor better than that prepared from the fresh flowers. (*P. J.*, xvi. 15.) It is not uncommon to employ the whole flower, including the calyx; but the product is less fragrant than when the petals only are used, as officially directed. A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the centre of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, coagulating the mucilaginous matter of the petals, and preventing it from passing over in the distillation. (*J. P. C.*, 1863, p. 497.) Rose water is sometimes made by distilling together water and the oil of rose. This is best performed by dropping 10 drops of oil of rose on a sponge and adjusting it in the upper part of a still in the body of which a gallon of water is placed; the steam from the boiling water will carry over portions of the oil, and the distillate will thus be impregnated. Alpers (*Am. Drug.*, 1896, 384) prepares rose water by dropping 10 drops of oil of rose into a liter of hot distilled water, agitating and filtering.

Rauschenberger improves the flavor by adding a trace of oil of cloves; 2.5 Gm. of oil of rose, 0.25 Gm. of oil of cloves are added to sufficient alcohol to make 100 Cc.; then 10 Cc. of this solution is added to 1000 Cc. of boiling water and the liquid cooled and filtered.

Rose water when properly prepared, has the perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters, it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. It may be kept in a bottle stoppered with a plug of absorbent cotton. This distilled water is chiefly employed, on account of its agreeable odor, in collyria and other lotions. It is wholly destitute of irritating properties, unless it contain alcohol.

AQUA SAMBUCI. *Br.*

ELDER-FLOWER WATER

(ă'quă sām-bū'ci)

Eau distillée de sureau, *Fr.*; Fliederblumen (Holunderblüthen) Wasser, *G.*

"Fresh Elder Flowers, 10 pounds (Imperial) or 5000 grammes (or an equivalent quantity of the flowers preserved, while fresh, with common salt); Water, 5 gallons (Imp. meas.) or 25 litres. Distil one-fifth." *Br.*

Elder flowers yield very little oil upon distillation; and, if the water be needed, it may be best prepared from the flowers. Haselden prefers the salted flowers to the fresh, for the reason stated under rose water. The preparation is little used in this country.

¹ "The rose water of commerce is a saturated solution of the essential oil of the rose flowers." *Br.*

AQUÆ. U. S.

WATERS [Medicated Waters]

(ἀ'quæ)

Aquæ stillatitiæ; Distilled Waters; Eaux Médicinales, *Fr. Cod.*; Eaux distillées, Hydrolats, *Fr.*; Aquæ Destillatæ, *P. G.*; Destillirte Wässer, *G.*; Acque distillate, *It.*

"The Medicated Waters, when prepared from volatile oils, are intended to be, as nearly as practicable, saturated solutions, which must be clear, and free from solid impurities. In the processes which follow, the solution of the volatile oils is facilitated by the use of purified tale; but the solution may, if preferred, be aided by replacing the purified tale by pulped or shredded filter paper; waters may also be made by the addition of volatile oils to hot water and separation of the excess of the former, or by the distillation of the drug or volatile oil with water, if by either of these methods the finished product corresponds in all respects with official requirements." *U. S.*

Under this head are included, in the *U. S. Pharmacopœia*, all preparations consisting of water holding volatile or gaseous substances in solution, many of which were formerly obtained by distillation, and some of which still continue to be so. They include the preparations formerly specially designated as "Distilled Waters," having been made by distilling water from plants or parts of plants containing volatile oil.

The Distilled Waters, as thus defined, hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation has been bestowed there upon the various conditions calculated to furnish the best products by the most convenient method. It would be doing injustice to the subject not to give it a distinct consideration in a work like the present.

Many vegetable substances impart their peculiar flavor to water distilled from them, and more or less of their medicinal properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapor and are condensed with it in the receiver. But as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the Distilled Waters, dried plants are sometimes used, because fresh plants are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odor by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavor. Some pharmacists prefer to employ the salted flowers in certain

instances, believing that the waters distilled from them keep better than when prepared from the fresh flowers. C. R. Tichborne discovered a method of preserving flowers which is said to answer even better than the use of salt. It consists simply in immersing the fresh flowers in glycerin, which preserves them with all their aromatic properties wholly unimpaired. The flowers, as of the elder, rose, and orange, should be gathered after full expansion, and packed firmly in wide-mouthed bottles or jars, but without crushing them. The glycerin is then to be poured on until it covers them, and the vessel closed. Tichborne has kept flowers in this way for two years, and at the end of that time procured from them Distilled Waters, of which the perfume has equalled that of the waters prepared from recent flowers. It is not necessary that the glycerin should be perfectly pure, but it should be without odor. (*P. J.*, 2d ser., vii. 135.)

The idea at one time prevailed, to a considerable extent, that Waters kept better if distilled from dried herbs than from fresh, and the opinion was true in regard to those prepared with the defective alembics of former times and by a naked fire; but experiment has sufficiently established the fact that, with a suitable apparatus, and a regular heat, the fresh herbs yield products which not only have a more agreeable odor of the plant, but keep quite as well as those from dried herbs.

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previous to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state until the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the solid matter, lest a portion of the latter, coming in contact with the sides of the vessel, be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the still above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil bath, regulated by a thermometer, or of a bath of solution of calcium chloride, by which any temperature may be obtained between 100° C. (212° F.) and 132.2° C. (270° F.), according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still termed a "jacketed body." To prevent the disagreeable effects of charring, and the excessive empyreumatic odor frequently noticed in Distilled Waters, caused by

the solid contents of the still coming into direct contact with the heated bottom, Remington devised an expedient which prevents the herb from touching the bottom and yet permits the water and steam to have free access to all parts of it. (See Pharmaceutical Still, under *Extracta*.)

A hemispherical No. 12 copper sieve with a handle and loosely fitting lid is filled with the herb and placed in the water in the still. If the bottom of the still be flat or nearly so, the rounded bottom of the cage must have a

very slight point of contact, and thus charring will be prevented. A convenient mode of applying heat by steam is by means of a coil of metal tubing placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a steam-cock, by which the pressure may be increased or the condensed water drawn off at will. If any volatile oil floats upon the surface of the Distilled Water, it may be separated.¹

From a series of experiments made in Paris in reference to the best mode of applying heat, it was concluded that as regards the great majority of aromatics the direct application of steam was preferable, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odor of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better; but that exceptions to the general rule are afforded by bitter almonds, cherry-laurel leaves, mustard, and horse-radish, in all of which the oil does not

pre-exist in the plant, but is formed upon contact with water; by woods, barks, and roots, the tissue of which cannot be sufficiently penetrated by steam; and by roses. (*J. P. C.*, Mai, 1861, p. 364.) Later experiments have led to the conclusion that even these substances are most advantageously treated by distillation with steam, and that, in fact, there is no exception to the rule.

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odor. They may be freed from this by exposure for a short time to the air before being enclosed in well-stoppered bottles, in which they should be preserved. When long kept, a viscid ropy matter is apt to form in them, and they become sour. This result has been ascribed to other principles, which rise with the oil in distillation and promote its decomposition. To prevent this decomposition, rectified spirit is sometimes added to the water employed in its distillation. But this addition is inadequate, and is in fact injurious, as the alcohol by long exposure to the air undergoes the acetous fermentation. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considered the mucosity which forms in Distilled Waters to be the result of a vegetative process, for which the presence of air is essential. He stated that so long as the water is covered with a layer of essential oil it undergoes no change, but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He stated that camphor exercises the same preservative influence over the Distilled Waters by resisting the vegetation, and that those in which the odor of camphor is developed keep better on that account. Finally, he observed that the more Distilled Water is charged with volatile oil, the more abundant is the mucosity when it has begun to form. Robiquet united with Henry and Guibourt, and with Virey, in recommending that all these waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use, and that the bottles should be quite filled, and then sealed or otherwise well stoppered, so as entirely to exclude the air. It is best that they should be small, and be closed with well-fitting glass stoppers. Thus treated, the Waters may be preserved without change for many years. (*J. P. C.*, xxi. 402.) This view is opposed to the experience of large producers of Distilled Waters; we have seen at Grasse hundreds of carboys stored away, containing distilled rose and orange flower waters, not only uncorked, but having only a thin piece of muslin laid over the lips to exclude dust. We were informed by the distillers that the waters retained their qualities for years far better when treated in this

¹ This direction is generally given; but, in a communication to the Pharmaceutical Society of Great Britain, Haselden recommends the excess of oil to be well shaken with the water, and the whole to be transferred to the stock vessel, where it may be allowed to rest, and the oil to separate. He thinks the water keeps better when thus treated, and the full strength is always insured. The stock vessel he prefers made of stoneware, and furnished with a tap placed two inches from the bottom, whereby the water may be drawn off clear when wanted for the ordinary shop bottles, the oil rising to the top, or sinking to the bottom, according to its sp. gr. (*P. J.*, xvi. 14, 15.)

It is of some importance to know the proportion which the aromatic submitted to distillation ought to bear to the amount of Distilled Water obtained. The following statement upon this point, based upon experiments, is contained in the *J. P. C.* (Mai, 1861, p. 367.) Fresh aromatic plants requiring one part of the plant for one of product: wormwood, black cherry, scurvy-grass, hyssop, cherry-laurel, lavender, balm, mint, peach leaves, roses, and sage;—fresh and dry aromatic plants requiring one part of the plant for two of product: bitter almonds, orange flowers, melilot, horse-radish, elder, and tansy;—dry and very aromatic plants requiring one part of the plant for four of product: angelica, green anise, juniper berries, chamomile, canella, cascarrilla, fennel, saffraas, linden flowers and valerian. Haselden prefers the process of distillation from the aromatic itself in the instances of dill, caraway fennel, cinnamon, and pimento, which are not apt to afford to the distilled water such matter as may cause it to become sour; but he prefers trituration for peppermint, spearmint, and pennyroyal waters. Haselden advises, however, that these waters should not be filtered, but that they should be prepared in quantity, allowed to settle, and drawn off as wanted. (*P. J.*, xvi. 14, 15.)

way than if stoppered tightly. We have frequently noticed microscopic plants belonging to the *Confervoidae* in the Distilled Waters contained in shop bottles standing on the shelves in the dispensing room, and if it be desired to keep Distilled Waters, the only sure way is to destroy the spores and prevent the admission of fresh ones by placing the bottles, filled to the lip with the Distilled Water, into a bath of boiling water, and, when thoroughly sterilized by the heat, inserting a plug of purified cotton if for immediate use; or if the waters are to be kept for a longer period, the well soaked corks should be driven into the mouths of the bottles, and immediately tied down, the top of the bottle dipped into melted sealing wax, and the bottles stored in a cool place.

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia in several instances. It is said to afford a more permanent product than the preceding, but does not always preserve the flavor of the plant.

In relation to most of the aromatic waters, the U. S. Pharmacopœia formerly directed that water should be impregnated with the volatile oil by trituration with magnesium carbonate, and subsequently filtered. This was by far the most simple and easy process. The resulting solution is nearly pure and permanent, and is perfectly transparent, the magnesium carbonate being separated by the filtration. Magnesium carbonate is preferable to magnesium oxide, as the latter sometimes gives a brownish color to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as salts of the alkaloids, mercuric chloride, and silver nitrate. The object of the magnesium carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. Precipitated calcium phosphate was used in the U. S. P. 1890 as a substitute for magnesium carbonate, but this has been shown to be slightly soluble in water; notwithstanding this objection, its use was sanctioned by the U. S. Pharmacopœia of 1890. W. S. Thompson of Washington, D.C., suggested the use of absorbent cotton as being free from all of these objections, and his views were substantially adopted by the Committee of Revision of the Pharmacopœia of 1880. E. V. Zoeller proposes to use a hand cotton-card to aid in pulling the filaments of cotton apart when a large quantity of medicated water is needed. (*N. R.*, 1883, p. 56.) Experience has shown, however, that the use of an insoluble powder to effect the minute division of the particles of oil, so as to present a large surface to the solvent, is a more practical and con-

venient method of making medicated waters. According to Robert Warington, this object may be better accomplished by porcelain clay, finely powdered glass or pumice-stone, which are wholly insoluble; and the London College employed finely powdered silica for the purpose. Talc or soapstone in powder, purified by washing with diluted hydrochloric acid, was adopted by the Committee on National Formulary (1888). (See *Talcum Purificatum*; also paper recommending it by Curtman, *Proc. A. Ph. A.*, 1887.) The U. S. P. (8th Rev.) recommends the use of purified talc, although several alternative processes are allowed; *i.e.*, the shaking of the oil with hot water until saturated and afterwards filtering; the use of paper pulp; or the distillation from the volatile oil or drug macerated in water, but the finished water must in all cases correspond to the product resulting from the use of talc. A very good way to make medicated waters when a volatile oil is directed, is that proposed by Percival, which is to heat the water required, pour it into a bottle and add the oil, cork tightly, shake occasionally until cool, then pour off and filter; this secures a medicated water free from foreign substances, and a saturated solution, most oils being more soluble in hot than in cold water. The Dublin College prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to the objection, already mentioned, against the medicated waters thus impregnated. They were, besides, feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the water should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of hydrogen sulphide and a carbonate, and the aromatic properties are quite lost. (See *A. J. P.*, xix. 303.) Hence the propriety of the official direction to employ distilled water.

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With potassium ferrocyanide, iron will give a blue color, zinc and lead white precipitates, and copper a rose color followed by a chestnut brown precipitate. Sodium sulphide causes with salts of iron, copper, or lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc a white precipitate. The Distilled Waters may be freed from these impurities by animal charcoal, previously well purified. The charcoal should be strongly shaken, eight or ten times in the course of a day, with the impure Water, which should then be allowed to rest, and the next day be filtered. Five grains of the charcoal will be sufficient for a gallon of the Distilled Water. (*J. P. C.*, Nov. 1862, p. 416.) The volatile oils may be re-

covered from the Waters containing them, or at least may be transferred to a spirituous menstruum, by mixing olive oil with the water, adding a little solution of potassium hydroxide so as to form a soap, and a consequent emulsion with the liquid, and then neutralizing by an acid. The fixed oil will rise to the surface, bringing the volatile oil along with it. The latter may then be separated from the former by agitation with alcohol. (T. P. Groves, *P. J.*, Feb. 1864.)

ARAROA. Br.

ARAROA

(ār-g-rō'ba)

"A substance found in cavities in the trunk of *Andira Araroba*, *Aguiar*, freed as much as possible from fragments of wood, dried and powdered." *Br.*

Crude Chrysarobin, Goa Powder, Poh di Bahia; Poudre de Goa, *Fr.*; Goa-Pulver, *G.*

Under the name of Chrysarobin, or Araroba, a medicine has long been used in Brazil; it is exported in considerable quantities to Portugal, whence it found its way through the Portuguese colonies into Eastern commerce. In the East Indies it is usually known as Goa Powder. Indeed, the identity of the two powders was first proved in 1875 by J. F. Dasilva Lima. (*P. J.*, v.) It has been supposed to be yielded by certain lichens, but was shown by R. A. Monteiro to be obtained from a leguminous tree abundant in the forests of the Brazilian province of Bahia, which was referred by E. M. Holmes to the genus *Casalpinia*, but which was determined by studies made in its native forests by J. M. de Aguiar, to be an undescribed *Andira*.

Andira Araroba, Aguiar, is a large tree, attaining a height of 100 feet, with a smooth trunk and a spheroidal, not very bushy head. The wood is yellowish, with numerous longitudinal canals, besides abundant irregular interspaces or lacunæ, in which the chrysarobin is deposited. (See *P. J.*, ix. 755; x. 42, 814.) The oldest trees yield the largest amount of the powder; the parts containing it are finely chipped or scraped off. The workmen who procure it often suffer severely from irritation of the eyes and face. As first obtained, chrysarobin is stated to be of a pale primrose yellow, but it rapidly darkens with age, so that in commerce it varies from a dull ochre to a dark chocolate or maroon-brown. It is sometimes a rather fine powder, but is usually more or less agglomerated, and not rarely contains fragments of woody tissue. It has been stated that Goa powder of late years is much weaker in its properties than that formerly obtained; this has been attributed to the scraping of the product from immature or young trees. This statement was not confirmed by the analysis of ten samples from the London market by Dun-

can and Tweedie. (*P. J.*, 1892, 543.) Its taste is bitter. It is insoluble in water and most menstrua, but yields as much as 80 per cent. of its weight to solutions of caustic alkalies and to benzene. The British Pharmacopœia requires that it should yield to hot *chloroform* not less than 50 per cent. of pure chrysarobin. Attfield analyzed Goa powder, and found, along with 2 per cent. of resin, 5.5 per cent. of woody fibre, 7 per cent. of bitter extractive, and from 80 to 84 per cent. of what he considered to be chrysophanic acid; but Liebermann and Siedler showed that this was not chrysophanic acid at all, but a substance easily convertible into the acid, which substance they called *chrysarobin*, and gave to it the formula $C_{30}H_{26}O_7$. (See *Chrysarobinum*.)

ARGENTI CYANIDUM. U. S.

SILVER CYANIDE

(ār-gēn'tī cŷ-ān'ī-dŭm)

$AgCN = 132.96$

"It should contain not less than 99.9 per cent. of pure Silver Cyanide, corresponding to 80.48 percent. of metallic silver. It should be kept in dark amber-colored vials, protected from light." *U. S.*

Cyanuret of Silver; Argentum Cyanatum; Cyanure d'Argent, *Fr.*; Cyansilber, Silbercyanid, *G.*

A process for preparing this salt is no longer official.

In the process of the U. S. P. 1870 all the silver contained in a given weight of silver nitrate, placed in a receiver in solution, is converted into cyanide by hydrocyanic acid, produced from potassium ferrocyanide by the action of sulphuric acid,

The materials in the retort are sufficient to produce a little more hydrocyanic acid than is necessary to convert the whole of the silver in the receiver into cyanide; so that the complete decomposition of the silver nitrate is insured. (See U. S. D., 18th ed., p. 223). Silver cyanide readily undergoes decomposition if exposed to the action of light. According to Glassford and Napier, the best way of obtaining silver cyanide is to add potassium cyanide to a solution of silver nitrate so long as a precipitate is formed.

Properties.—Silver cyanide is officially described as "a white powder, without odor or taste, permanent in dry air, but gradually turning brown on exposure to light. Insoluble in water, alcohol, or cold nitric acid, but soluble in boiling nitric acid with evolution of hydrocyanic acid; also soluble in ammonia water, sodium thiosulphate T.S., and potassium cyanide T.S. When heated in a porcelain crucible the salt fuses, gives off cyanogen gas, and, on ignition, leaves a residue of metallic silver amounting to 80.48 percent. of its original weight." *U. S.*

Its best solvent is potassium cyanide solution. It has no medicinal uses, but is official solely for the purpose of making hydrocyanic acid.

Off. Prep.—Acidum Hydrocyanicum Dilutum, U. S.

ARGENTI NITRAS. U. S., Br.

SILVER NITRATE

(ār-gēn'tī nī'trās)

$\text{AgNO}_3 = 168.69$

"It should contain not less than 99.9 per cent. of pure Silver Nitrate, and should be kept in dark amber-colored vials, protected from light." U. S. "A salt, AgNO_3 , prepared by the interaction of nitric acid and silver." Br.

Nitrate of Silver, Lunar Caustic; Azotas (Nitrates) Argenticus; Azotate d'Argent cristallisé, *Fr. Cod.*; Nitre lunaire, *Fr.*; Argentum Nitricum Crystallissimum, *P. G.*; Salpetersaures Silberoxyd, Silbersalpeter, Silberniträt, *G.*; Nitrato di argento cristallizzato, *It.*; Nitrato Argentico cristallizado, Nitrato de plata, *Sp.*

The U. S. and Br. Pharmacopœias do not give processes for making this salt. The U. S. Pharmacopœia 1870 gave the following: "Take of Silver, in small pieces, *two troy-ounces*; Nitric Acid *two troyounces and a half*; Distilled Water *a sufficient quantity*. Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapors cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stoppered bottle. By evaporating the mother-water, more crystals may be obtained." U. S. 1870.

In the above process two details deserve notice. One of these is the direction to cover the materials in the evaporating dish, during the continuance of the reaction, with a glass funnel. This is in order to prevent the escape of fumes and to economize the nitric acid, a portion of which rises in vapor, and, being condensed on the inner surface of the funnel, falls again into the dish. The second detail is the fusion of the salt before being dissolved; the effect is to decompose any copper nitrate that might have been derived from the silver, which, if coin be employed, always contains copper. The heat decomposes the copper nitrate, and the comparatively insoluble oxide is

formed, which remains on the filter when the mass is subsequently dissolved in water and filtered, the silver nitrate not being decomposed by the heat used.

A practical method used in Calcutta for separating the copper nitrate depends upon the fact that strong nitric acid only slightly dissolves silver nitrate in the presence of copper nitrate. The silver nitrate is crystallized out from the first solution as long as it can be obtained pure, and the bluish-green mother liquor is evaporated to dryness; the powdered salt, placed in a funnel stopped with asbestos, is percolated with nitric acid (sp. gr. 1.42). This washes out all of the copper nitrate, and the silver nitrate can be freed from the adhering nitric acid by heat. (*P. J.*, 1897, 61.)

During the solution of silver in nitric acid, part of the acid is decomposed and nitric oxide is given off, which becomes red by contact with the atmosphere, and the oxygen oxidizes the silver. This is taken up by the remainder of the acid, and produces silver nitrate in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both hydrochloric and sulphuric acids, should never be used. The hydrochloric acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble silver sulphate. It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which, when washed with solution of ammonia, is perfectly pure. (*A. J. P.*, 1862, p. 368.) For an account of the manufacture of silver nitrate, see *D. C.*, 1887, p. 3.

Properties.—Silver nitrate is in "colorless, transparent, tabular, rhombic crystals, becoming gray or grayish-black on exposure to light in the presence of organic matter; without odor, but having a bitter, caustic, and strongly metallic taste. Soluble in 0.54 part of water, and in 24 parts of alcohol at 25° C. (77° F.); in 0.1 part of boiling water, and in 5 parts of boiling alcohol. When heated in a porcelain crucible to about 200° C. (392° F.), the salt melts, forming a faintly yellow liquid, which, on cooling, congeals to a pure white, crystalline mass. At a higher temperature it is gradually decomposed with evolution of nitrous vapors." U. S.

"Soluble in ether and glycerin." *Br.* The solution stains the skin an indelible black color, and is itself discolored by the most minute portion of organic matter, for which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite compounds with albumin and fibrin. The solution also stains linen and muslin in a similar manner, and hence its use in making the so-called indelible ink. To remove these stains, W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into silver iodide. The iodide is then dissolved by a solution of sodium thiosulphate, made with from half a drachm to a fluidounce of water, or by a moderately diluted solution of potassium hydroxide, and the spots are washed out with warm water. Silver stains may also be taken out by a solution of two and a half drachms of potassium cyanide, and fifteen grains of iodine, in three fluidounces of water. H. Kraetzer recommends, instead of potassium cyanide, a solution of 10 parts ammonium chloride and 10 parts corrosive sublimate in 100 parts of water, with which the stains are said to be removed readily from the hands, and from linen, wool, and cotton without injuring the fabric. (*A. Pharm.*, 1880, 52.) Silver nitrate is incompatible with most spring and river waters, on account of a little common salt usually contained in them; with soluble chlorides; with hydrogen sulphide, sulphuric, hydrochloric, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime water, and with astringent infusions. It is sometimes improperly prescribed in pill with tannic acid, by which it is decomposed. Silver nitrate is an anhydrous salt, consisting of one atom of silver, combined with the monatomic group characteristic of nitric acid.

Impurities and Tests.—Hydrochloric acid or a solution of sodium chloride, added in excess to one of silver nitrate, should throw down the whole of the silver as a white curdy precipitate (darkening on exposure to light), and nothing besides. This precipitate should be entirely soluble in ammonia. If not so, the insoluble part is probably lead chloride. If the supernatant liquid, after the removal of the precipitate, be discolored or precipitated by hydrogen sulphide, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. The solution, after precipitation by hydrochloric acid and filtration, should leave no residue when evaporated. A piece of the salt, heated on charcoal by the blow-pipe, melts, deflagrates, and leaves behind a whitish metallic coating. After all, the best sign of the purity of silver nitrate is the characteristic appearance of the crystals. "An aqueous solution of the salt is neutral to litmus paper, and yields, with hydrochloric acid, a white precipitate, which is readily dissolved by ammonia water, the liquid not acquiring a blue color (absence of *copper*). If 5 Cc. of an aqueous solution of the salt (1

in 10) be mixed with 20 Cc. of hot diluted sulphuric acid, and heated to boiling, no turbidity should be perceptible, and upon standing, no white precipitate should be deposited (absence of *lead*). If a portion of an aqueous solution (1 in 10) be completely precipitated by hydrochloric acid, filtered, and the filtrate evaporated to dryness, no residue should be left (absence of *foreign salts*). If 0.5 Gm. of Silver Nitrate, dissolved in 10 Cc. of distilled water, be well mixed with 30 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 0.4 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color." *U. S.* "1 gramme dissolved in 15 cubic centimetres of water affords with *hydrochloric acid* a precipitate, which, when thoroughly washed and dried, should weigh 0.843 gramme. The filtrate, when evaporated to dryness on a water-bath, should leave no residue." *Br.*

Uses.—When silver nitrate in a pure state is brought in contact with a living tissue, it acts as an escharotic. Owing to the formation of a dense film of coagulated albumin, the depth of its action is very limited; the albuminous coating is at first white, but soon becomes blackish, owing to the reduction of the silver. The aqueous solution of the salt is, if not too strong, a local stimulant and astringent, and is very largely employed (20 grains in a fluidounce) in ordinary *angina*, or more concentrated (30 grains in a fluidounce) in *diphtheria*, and is also used in *inflammations of the urethral and conjunctival mucous membrane*; for the latter purpose the strength should usually not exceed one or two grains to the ounce. As a counter-irritant, stimulant, and alterative, or an escharotic in various *external ulcerations, morbid growths*, etc., silver nitrate finds a very wide use. It is largely employed, also, internally in *inflammations and ulcerations of the alimentary tract*, such as *subacute gastritis, pyrosis, ulcer of the stomach, chronic diarrhœa, catarrh of the gall ducts*, etc. In all stomachic diseases it should be given half an hour before eating, so as to reach as thoroughly as possible the gastric mucous membrane. Boudin of Marseilles, employed it in *typhoid fever*, and Wm. Pepper followed this practice with asserted brilliant results. As it has been found in all the tissues of the body, it is undoubtedly absorbed. It is soluble in peptones, and is probably so taken up, although some believe that it is converted in the stomach into a soluble double chloride with sodium or potassium. It is never used in practical medicine to produce an acute impression on the general system, but was at one time much employed as a slowly acting alterative in certain nervous affections, especially *epilepsy* and *chronic spinal inflammations*, such as *locomotor ataxia, spasmodic tabes, tabes dorsalis*, etc., but this method of treatment has about passed out of vogue. The occasional production of a slate-colored discoloration of the skin is a great drawback to the long-con-

tinued use of the nitrate, but it probably never occurs under a course of the remedy of less than two months. It affects also the mucous membrane, and, according to Branson (confirmed by Wm. Pepper), an indication of the approach of discoloration is furnished by the occurrence of a dark blue line on the edges of the gums, very similar to that produced by lead, but somewhat darker. When once produced, the discoloration seems to be permanent, although L. P. Yandell has reported two cases in which the discoloration of the skin disappeared during a course of potassium iodide. (*N. R.*, July, 1873.)

For internal exhibition, the physician should always prescribe the crystals, and never direct the fused nitrate, which may not be pure. Silver nitrate should always be given in pill, as the solution is decomposed by the liquids of the mouth. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage, preferably powdered sugar of milk with an excipient of glycerite of starch. But, as all organic substances decompose it more or less, Vée proposes the use of inorganic matter, such as potassium nitrate, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass. (*J. P. C.*, Mai, 1864, p. 408.)

When ingested in sufficient dose, silver nitrate is a violent poison, and has several times caused death. The symptoms are those of toxic gastro-enteritis, with marked constitutional disturbance, especially coma, convulsions, paralysis, and profound alteration of the respiration. The treatment of the poisoning resolves itself into the use of the ordinary antidotes (common salt, soap, alkalies, etc.), and the use of stimulants to maintain the circulation if needed.

Dose, one-fourth to one-half grain (0.016 to 0.032 Gm.).

ARGENTI NITRAS FUSUS. U. S. (Br.)

MOULDED SILVER NITRATE [Fused Silver Nitrate,
Lunar Caustic, Toughened Caustic]

(är-gĕn'tī nī'trās fū'sūs)

Argenti Nitras Induratus, Br.; Fused Nitrate of Silver, Lapis Infernalis, Argentum Nitricum Fusum; Crayons d'Azotate d'Argent, *Fr. Od.*; Azotas (Nitras) Argenticus Fusus; Azotate d'Argent fondu, *Pierre infernale, Fr.*; Gehärteter Höllestein, *Geschmolzenes Salpetersaures Silberoxyd, Silberniträt, G.*; Nitrato di argento fuso, *It.*; Nitrato argéntico fundido, *Piedra infernal, Sp.*

* "Silver Nitrate, one hundred grammes [or 3 ounces av., 231 grains]; Hydrochloric Acid, four grammes [or 62 grains]. To the Silver Nitrate, contained in a porcelain dish, add the Hydrochloric Acid, and melt the mixture at as

low a temperature as possible. Stir well, and pour the melted mass into suitable moulds. It should be kept in dark amber-colored vials, protected from light." *U. S.*

"Silver Nitrate, 475 grains (Imperial) or 95 grammes; Potassium Nitrate, 25 grains (Imp.) or 5 grammes. Fuse and mix thoroughly in a capsule of platinum or thin porcelain, and pour the melted mass into proper moulds." *Br.*

For most purposes it is desirable to have the silver nitrate less brittle than in its pure state. J. L. Smith of Louisville, Ky., found that this could be effected by adding a little silver chloride, which rendered the stick tough, without materially impairing its efficiency. E. R. Squibb proposed to accomplish the object by adding 40 grains of hydrochloric acid, with half a fluidounce of distilled water, to two ounces of silver nitrate, heating the mixture by means of a sand bath to dryness, and then melting and casting into moulds. (*Proc. A. Ph. A.*, 1858.) This process has been practically adopted in the *U. S. Pharmacopœia*. In order to keep the sticks from becoming discolored during the casting process, it is advisable to add a diluted nitric acid (1 in 5) occasionally to the melted nitrate, and carefully prevent the mass from becoming overheated. In the British process the "toughening" is effected by the addition of 5 per cent. of potassium nitrate. In our opinion, this is not as efficient as is the use of hydrochloric acid. As the salt while melting penetrates a common crucible, the fusion is performed in one of porcelain or platinum, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its boiling over. Sometimes small portions of the liquid are spurted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should not be greased, as the organic matter would partially decompose the fused salt.

Properties.—Moulded silver nitrate, as prepared by the above process, is in the form of hard brittle sticks of the size of a goose quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, through organic matter or conversion through hydrogen sulphide contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Scanlon, who finds that silver nitrate in a clean glass tube hermetically sealed undergoes no change by exposure to light. The sticks often become dark colored and nearly black on the surface, and when broken across, exhibit a crystalline fracture with a radiated surface. Fused silver nitrate, when pure, is wholly soluble in distilled water; but even fair samples of the moulded salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt having been exposed to

too strong a heat in fusion. Stein (*S. W. P.*, 6, 10, 1877) recommends a plan for obtaining sticks of lunar caustic of special diameter or length by taking a glass tube or rod of the required outside diameter and wrapping around it moistened parchment paper, pasting the edges, tying the lower end, and drying. The melted lunar caustic is poured into the paper mould, held upright in a test tube, and allowed to cool by standing. *Elastic crayons* of silver nitrate may be made by taking a laminaria tent 1-10th of an inch (0.002 Mm.) in diameter, dipping it into thick mucilage, rolling it in finely powdered lunar caustic, and drying it. (Pajot.) Entirely black lunar caustic is sometimes seen in France, which contains about 2 per cent. of potassium nitrate and the same quantity of black manganese oxide. *Heller's caustic pencils* look like ordinary lead pencils, and consist of long, thin sticks of lunar caustic, encased in wood; they may be sharpened like lead pencils, and the point protected by a cap to prevent injury when not in use. "A white, hard solid, generally in the form of pencils or cones of a fibrous fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter; odorless, and having a bitter, caustic, and strongly metallic taste. Soluble, with the exception of about 5 percent. of silver chloride, in 0.54 part of water, and in 24 parts of alcohol at 25° C. (77° F.); in 0.1 part of boiling water, and in 5 parts of boiling alcohol. The portion left undissolved by water should be completely soluble in ammonia water." *U. S.*

Impurities and Tests.—Moulded silver nitrate is liable to contain free silver from having been exposed to too high a heat, lead and copper nitrates from the impurity of the silver dissolved in the acid, and potassium nitrate from fraudulent admixture or otherwise. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but if there be much free silver it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark gray color. The mode of detecting lead and copper is explained under silver nitrate. (See *Argenti Nitras*.) "A clear, aqueous solution of Moulded Silver Nitrate, decanted from the insoluble portion, should be neutral to litmus paper, and should respond to the tests of identity and purity stated under *Argenti Nitras*. If 0.5 Gm. of Moulded Silver Nitrate, dissolved as completely as possible in 10 Cc. of water, be thoroughly mixed with 30 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 1.9 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color." *U. S.* In order to detect potassium nitrate, a solution of the suspected salt should be treated with hydrochloric acid in excess, to remove silver, and with hydrogen sulphide, to throw down other metals if they happen to be present.

The filtered liquid, if the salt be pure, will entirely evaporate by heat; if it contains potassium nitrate, this will be left, easily known by its properties as a nitrate. This impurity sometimes exists in moulded silver nitrate in large amount, varying, according to different statements, from 10 to 75 per cent. (See *Argenti Nitras Mitigatus*.) According to Christison, it may be suspected if the sticks present a colorless fracture. Pollacci (*J. P. C.*, 4e sér., xvii. 160), states that if silver nitrate, after having been heated in a porcelain capsule to redness and cooled, imparts an alkaline reaction to water, it contains nitre. In the *Br. Pharmacopoeia* the following method is given for testing toughened silver nitrate for impurity; the British preparation contains no hydrochloric acid. "1 gramme, dissolved in 15 cubic centimetres of water, should yield with hydrochloric acid a precipitate which, when washed and dried, should weigh 0.8 gramme, and the filtrate when evaporated should leave a white residue."

Uses.—Moulded silver nitrate should be restricted to external use. Externally applied, the moulded nitrate acts variously as a stimulant, vesicant, and escharotic, and may be employed either dissolved in water or in the solid state. A drachm of the moulded salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. But moulded silver nitrate is most frequently employed in the solid state; and, as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. If the moulded nitrate be rubbed gently over the moistened skin until this becomes gray, it generally vesicates, causing usually less pain than is produced by cantharides. The fused nitrate is also employed to destroy strictures of the urethra, warts and excrescences, fungous flesh, incipient chancres, and the surface of other ulcers.

It is often of service lightly applied, either in concentrated solution or in stick, to ulcers in expediting their cicatrization. It is very largely employed in the local treatment of inflammations of the mucous membrane, as in cystitis, leucorrhœa, gonorrhœa, conjunctivitis, faucitis, laryngitis, etc. In these cases the strength of the solution must be adapted to the susceptibility and the exact condition of the membrane. In cases of intense and especially of specific inflammations, the solution may be a saturated one, the object being to destroy the specific granulations; thus, in gonorrhœal conjunctivitis, and in virulent diphtheria faucitis, even the solid stick is used by some practitioners, whereas in ordinary conjunctivitis the strength should rarely be above one or two grains to the ounce, and in faucitis twenty to forty grains to the ounce. Strong solutions of silver nitrate are sometimes used for the aborting of a gonorrhœa, but the treatment is usually considered dangerous, as liable to increase the intensity of the inflammation if unsuccessful.

In the advanced stages of gonorrhœa a solution of three to five grains to the ounce may be injected.

Lunar caustic is also frequently used as a topical remedy in various superficial inflammations. The method originated in 1820, by John Higginbottom, of treating *erysipelas* by silver nitrate still finds favor with some of the profession. After thorough washing of the skin with soap and water, and afterwards with pure water, and subsequent drying, a concentrated solution of twenty grains of silver nitrate to a drachm of distilled water is applied freely on the inflamed surface and beyond it on the healthy skin by means of a linen mop. In various inflammations of the subcellular tissues silver nitrate often acts advantageously; thus, applied to the skin in sufficient concentration to blacken the surface, it will sometimes avert a *felon* or an *epididymitis*. It has been employed by injection for the radical cure of *hydrocele*, and in solid stick applied as a fine point to each *pustule* of *small-pox* upon the face for the prevention of pitting.

ARGENTI NITRAS MITIGATUS.

MITIGATED SILVER NITRATE [Argenti Nitras Dilutus, Pharm. 1890, Diluted Silver Nitrate, Mitigated Caustic]

(är-gën'ti nī'trās mīt-l-gä'tūs)

"It should contain not less than 33.3 percent. of pure Silver Nitrate." U. S.

Silver and Potassium Nitrate; Lapis Infernalis nitrat; Crayons d'Azotate d'Argent mitigé, Pierre infernale diluée, Fr.; Argentum Nitricum cum Kallo nitrico, P. G.; Salpeterhaltiges Silbernitrat, Salpeterhaltiger Höllenstein, G.; Nitrato di argento fuso con nitrato di potassio, It.; Nitrato argéntico mitigado, Piedra infernal mitigada, Sp.

*"Silver nitrate, *thirty grammes* [or 463 grains]; Potassium Nitrate, *sixty grammes* [or 2 ounces av., 51 grains]. Melt the salts together in a porcelain crucible, at as low a temperature as possible, stirring the melted mass well until it flows smoothly. Then pour it into suitable moulds. It should be kept in dark amber-colored vials, protected from light." U. S.

"Silver Nitrate, 1 ounce (Imperial) or 20 grammes; Potassium Nitrate, 2 ounces (Imp.) or 40 grammes. Fuse and mix thoroughly in a capsule of platinum or thin porcelain, and pour the melted mass into proper moulds." Br.

The introduction of these preparations grew out of the frequent demand for a fused silver nitrate which would not be so severe in its action as the pure article. The manufacturers have been furnishing for many years a "No. 2 Lunar Caustic," which contains 67 per cent. of pure silver nitrate; the diluted nitrate of the U. S. P. 1880 contained 50 per cent. of lunar caustic, but the present Pharmacopœia has further reduced the strength to 33.3 per cent., and it is now identical with the British preparation.

Properties.—Mitigated silver nitrate is officially described as "a white, hard solid, generally in the form of pencils or cones of a finely granular fracture, becoming gray or grayish-black on exposure to light in the presence of organic matter; odorless, and having a caustic, metallic taste. Its aqueous solution is neutral to litmus paper. Each of its constituents retains the solubility in water and in alcohol stated respectively under *Argenti Nitras* and *Potassii Nitras*. An aqueous solution of Mitigated Silver Nitrate yields with a slight excess of hydrochloric acid a white precipitate, which is readily soluble in ammonia water. The filtrate from this precipitate, when evaporated to dryness, yields a white residue which is completely soluble in water, and this solution, when concentrated, affords a white, crystalline precipitate with sodium bitartrate T.S. If 1 drop of diphenylamine T.S. be mixed with 5 Cc. of an aqueous solution of the salt in a test-tube, and sulphuric acid be carefully poured in, so as to form a separate layer, a blue color will appear at the line of contact. If to an aqueous solution of Mitigated Silver Nitrate a slight excess of ammonia water be added, it should neither assume a blue color (absence of copper), nor show any turbidity (absence of lead and bismuth.) If 1 Gm. of Mitigated Silver Nitrate, dissolved in 10 Cc. of water, be well mixed with 20 Cc. of tenth-normal sodium chloride V.S. and 3 drops of potassium chromate T.S., not more than 0.3 Cc. of tenth-normal silver nitrate V.S. should be required to impart to the liquid a permanent red color." U. S.

"White or grayish-white cylindrical rods or cones; freely soluble in water, but only sparingly so in alcohol (90 per cent.). . . 3 grammes dissolved in 15 cubic centimetres of water should afford with hydrochloric acid a precipitate, which, after washing with hot water and drying, weighs 0.843 gramme." Br.

Uses.—This preparation is used only externally. It is similar in its action to the fused nitrate, but less energetic.

ARGENTI OXIDUM. U. S., Br.

SILVER OXIDE

(är-gën'ti ős'l-düm)

$\text{Ag}_2\text{O} = 230.12$

"It should contain 99.8 percent. of pure Silver Oxide, corresponding to not less than 92.9 percent. of pure metallic silver, and should be kept in dark amber-colored vials. Silver Oxide should not be triturated with readily oxidizable or combustible substances, and should not be brought in contact with ammonia." U. S. "Silver Oxide, Ag_2O , is prepared by mixing solutions of silver nitrate and calcium hydroxide." Br.

Argentum Oxydatum, Argentic Oxide; Oxyde d'Argent, Fr.; Silberoxyd, G.

A process for preparing silver oxide has not been adopted in either of the present U. S. or Br. Pharmacopœias; that of the U. S. Pharmacopœia of 1870 is as follows: "Take of Nitrate of Silver *four troyounces*; Distilled Water *half a pint*; Solution of Potassa *a pint and a half*, or a *sufficient quantity*. Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well-stopped bottle, protected from the light." U. S. 1870.

Silver oxide was introduced into the U. S. Pharmacopœia of 1850, and was adopted in the Br. Pharmacopœia from the Dublin. In the processes for making it, silver nitrate is decomposed by potassium hydroxide or lime, the oxide being precipitated, and potassium nitrate or calcium nitrate, as the case may be, remaining in solution. When thus obtained, the oxide is an olive-brown powder. If the potassium hydroxide used be not wholly free from carbon dioxide the precipitated oxide will be contaminated with some silver carbonate. According to Borland of London, the carbonate is sometimes sold for the oxide. A third process for obtaining this oxide is that of Gregory, which consists in boiling the moist, recently prepared silver chloride with a very strong solution of potassium hydroxide (sp. gr. 1.25 to 1.30), when by double decomposition, silver oxide and potassium chloride are formed.

Properties and Tests.—"A heavy, dark brownish-black powder, liable to reduction by exposure to light, odorless, and having a metallic taste. Very slightly soluble in water, to which it imparts an alkaline reaction; insoluble in alcohol; it is readily and completely soluble in nitric acid without effervescence (absence of carbonate or chloride). When heated in a porcelain crucible to about 250° to 300° C. (482° to 572° F.), it is rapidly decomposed, with the evolution of oxygen, leaving a residue of metallic silver. The solution of the Oxide in nitric acid should be colorless, and should respond to the reactions and tests stated under *Argenti Nitras*. If 0.5 Gm. of the Oxide be ignited in a porcelain crucible, it should yield not less than 0.464 Gm. of pure metallic silver." U. S.

"A brown powder, which at a low red heat gives off oxygen and yields metallic silver. It dissolves in *nitric acid* without the evolution of any reddish fumes (absence of metallic silver). Each gramme, dissolved in *nitric acid*, should yield with *hydrochloric acid* a precipitate, which when thoroughly washed and dried, weighs 1.237 grammes. It should yield no characteristic reaction with the tests for lead, copper, or iron. Silver Oxide is liable to decompose with violence when mixed with creosote, phenol, potassium permanganate, and many other substances." Br. When its solution in nitric acid is precipitated by sodium chloride in excess, the

supernatant liquid is not discolored by ammonium sulphide. The non-action of this test shows the absence of most foreign metals, especially copper and lead. It parts with its oxygen with great facility, being decomposed by many organic substances; in this way it causes sulphur, amorphous phosphorus, or tannin to take fire when rubbed together with it quite dry, in a mortar.

Uses.—This oxide has been proposed as a substitute for silver nitrate, as having the general therapeutic virtues of the latter, without its escharotic effect and its objectionable property of discoloring the skin. Experience, however, has shown that it will tint the skin. (N. Y. M. J., June, 1869; P. M. T., vi.) It may be used in gastric and other catarrhs but is inferior to the nitrate. If pills are ordered, they should not be made with honey, confection of rose, or other excipient containing glucose; and, indeed, most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. A case is recorded in which pills containing it exploded violently in the pocket of the patient. (See Jackson, P. J., xi. 552.) An ointment from five to ten grains to the drachm, has been used as an application to *venereal sores*, and to the urethral membrane in *gonorrhœa*; it should be smeared on a bougie.

Dose, one grain (0.065 Gm.).

ARGENTUM

SILVER

(*är-gén'tum*)

Ag = 107.12

Argentum purificatum; Argent raffiné, Argent, Fr.; Silber, Raffinirtes Silber, G.; Argento, It.; Plata, Sp.

Silver is found at times in the metallic state, usually crystallized, also associated with gold, antimony, arsenic, or mercury; but usually it occurs as a sulphide, pure or mixed with other sulphides, as those of copper, lead, and antimony. It is sometimes found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru and our own Rocky Mountain States and Territories; the richest in Europe are those of Norway, Hungary, and Transylvania. Mines have been opened and profitably worked in California and Nevada, but at present it is chiefly Colorado and Montana which furnish the great bulk of the American silver production. Idaho, Utah, and Arizona also contain very rich silver deposits. The principal ore is the sulphide. The mineral containing silver which is most disseminated is argentiferous galena, which is lead sulphide containing a little silver sulphide. Argentiferous galena exists in several localities in the United States. Native silver is associated, in small quantities, with the native copper of the Lake Superior region, and a little of it has come into the market. The two metals, though more or less mixed, are yet quite distinct, never being alloyed to any con-

siderable extent, showing conclusively that the deposits have not undergone igneous fusion at any time, but that the metals have deposited from solution. The production of silver in the United States for 1902 was 55,500,000 troy-ounces, valued at \$29,415,000; for 1903, 54,300,000 troyounces, valued at \$29,322,000, and for 1904, 53,603,000 troyounces, valued at \$30,982,534. The United States production is exceeded only by that of Mexico and these two countries furnish almost exactly two-thirds of the world's production of silver.

Extraction.—Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation*. When the ore is principally the sulphide, it is mixed with a tenth of sodium chloride and roasted in reverberatory furnaces. As fast as the sulphide is oxidized to sulphate, this reacts with the sodium chloride, forming silver chloride and sodium sulphate. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, $\frac{1}{3}$ of its weight of water, and about 1–17th of iron in flat pieces, and subjected for sixteen or eighteen hours to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as iron chloride, while the reduced silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leather bags, through the pores of which the excess of mercury passes, a solid amalgam being left behind. This is then subjected to heat in a distillatory apparatus, by means of which the mercury is separated from the silver, which is left in a porous mass. In Peru and Mexico the process is similar to that above given, common salt and mercury being used; but slaked lime and iron sulphide are also employed, with little effect.

When argentiferous galenas are worked for the silver they contain, they are at first reduced, and the argentiferous lead obtained is fused on a large, oval, shallow vessel called a *test*, and exposed to the blast of a bellows, whereby the lead is oxidized, half vitrified, and driven off the test in scales, in the form of *litharge*. The operation being continued on successive portions of argentiferous lead, the whole of the lead is separated, and the silver, not being oxidizable, accumulates on the test as a brilliant fused mass, until its amount is sufficient to be removed. The time required for the separation is much abridged by the process of Pattinson. This consists in allowing the melted alloy to cool slowly, and separating the crystals which first form, consisting mainly of lead, by means of a perforated ladle. The residue is a very fusible alloy of lead and silver, in which the latter metal is in large proportion, and from which it can be easily separated by cupellation or other means.

Properties.—Silver is a white metal, very brilliant, tenacious, malleable, and ductile. In malleability and ductility it is inferior only to gold. It is harder than gold, but softer than copper. Its atomic weight is 107.12, symbol

Ag, and sp. gr. from 10.4 to 10.5. What is termed "molecular silver" is obtained as a very fine powder, by reducing freshly precipitated silver chloride with formaldehyde in the presence of potassium carbonate. "*Colloidal silver*" is obtained by heating to 100° C. silver citrate in a stream of hydrogen or by passing an electric current between silver electrodes in water. It dissolves in water to a red solution which does not dialyze. Both these allotropic forms are converted into ordinary silver by fusion. Silver forms but one well-characterized oxide. Exposed to a full red heat, it enters into fusion (melting at 954° C.), and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish of silver sulphide by the action of hydrogen sulphide in the atmosphere, from which it may be freed by washing it with a strong solution of potassium cyanide, and, as soon as it becomes bright, washing it with water and drying it. (*Chem. News*, 1866, p. 12.) It is entirely soluble in diluted nitric acid. If any gold be present, it will remain undissolved as a dark-colored powder. From the nitric solution the whole of the silver may be thrown down by sodium chloride, as a white precipitate of silver chloride, characterized by being completely soluble in ammonia. If the remaining solution contain copper or lead, it will be precipitated or discolored by hydrogen sulphide. "The solution, deprived of silver by means of sodium chloride, and filtered, is not colored, or but slightly so, and is not precipitated by hydrosulphuric acid." *U. S.* 1870. "If ammonia be added in excess to a solution of the metal in nitric acid, the resulting fluid exhibits neither color nor turbidity" (*Br.* 1885); proving the absence of copper, lead, and other metals. "10 grains dissolved in a little nitric acid, the solution diluted with water, and diluted hydrochloric acid added in slight excess, yields a white precipitate which, when thoroughly washed, dried, and heated, weighs 13.25 grains." *Br.* 1885.

ARMORACIÆ RADIX. Br.

HORSE RADISH ROOT

(är-mō-rā'ci-æ rā'dix)

"The fresh root of *Cochlearia Armoracia*, *Linn.*, collected from cultivated plants." *Br.*

Armoracia, Br. 1864; Raifort sauvage, Montarde des Molnes, Radis de Cheval, Cran de Bretagne, *Fr.*; Meerrettig, *G.*; Rabano rusticano (*Raiz de*), *Sp.*

Roripa Armoracia (L.), Hitchcock. *Cochlearia Armoracia* (L.), Willd., *Sp. Plant.* ii. 451; Woodv., *Med. Bot.* p. 400, t. 145. *Cochlearia rusticana*, Lam. *Armoracia sativa*, Bernheim.—The root of this plant is perennial, sending up numerous very large leaves from the midst of which a round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-shaped, waved, scolloped on the edges, sometimes pinnatifid, and stand upon strong footstalks. Those of the stem are

much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, peduncled, and form thick terminal clusters. The calyx has four ovate, deciduous sepals, and the corolla an equal number of obovate petals, twice as long as the calyx, and inserted by narrow claws. The pod is small, elliptical, crowned with the persistent stigma, and divided into two cells, each containing from four to six seeds.

The horse-radish, indigenous to Western Europe, is to some extent naturalized in the United States, and is largely cultivated for culinary purposes.

The root, which is official in its fresh state, is long, conical at top, then nearly cylindrical for some inches, at last tapering, whitish externally, very white internally, fleshy, of a strong pungent odor when scraped or bruised, and of a hot, biting, somewhat sweetish, and sometimes bitterish taste. Its virtues are imparted to water and alcohol. They depend upon a *volatile oil*, which is dissipated by drying, the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The oil may be obtained by distillation with water. It is colorless or pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Hubatka considers it as identical with the volatile oil of mustard. He combined it with ammonia and obtained crystals of *thiosinamin*, $\text{NH}_4\text{CS.N}(\text{C}_2\text{H}_5)_2$, which agreed with that produced from mustard oil. (*J. P. C.*, 3e sér., v. 42.) According to Gutret, only six parts of it are obtained from 10,000 of the root. Besides this principle, the fresh root contains, according to the same chemist, a bitter resin in minute quantity, sugar, extractive, gum, starch, albumen, acetic acid, calcium sulphate and acetate, water, and lignin. A. Hilger found in the ashes of the root of horse-radish the following: calcium, magnesium, potassium, a trace of sodium and iron in combination with sulphuric, hydrochloric, carbonic, phosphoric, and silicic acids. (*Chem. Cb.*, p. 597, 1878; *A. J. P.*, 1879, p. 21.) From observations made by F. L. Winckler, it may be inferred that *myronic acid* exists in the root combined with potassium hydroxide, and that it is from the reaction between this acid, *myrosine*, also existing in the root, and water, that the volatile oil is produced, in the same manner as oil of mustard from mustard seed. (See *Sinapis*.) Horse-radish when distilled with alcohol yields none of the oil. Buried in cool sand the root may be kept for some time without material injury.

It is said that if to the powder of the dried root which has become apparently inert, the emulsion of white mustard seed containing *myrosine* be added, it reacquires its original irritant properties; so that it is the *myrosine* and not the potassium *myronate* which is injured by dry-

ing. Hence the powdered root may be added with advantage to mustard in preparing cataplasms, pediluvia, etc. (*J. P. C.*, xxvii. 268.)¹

Uses.—Horse-radish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion.

Dose, half a drachm (2 Gm.) or more, grated or cut into small pieces.

Arnica montana, Willd., *Sp. Plant.* iii. 2106; *B. & T.* 158.—This is a perennial herbaceous plant, having a woody, brownish, horizontal rhizome, from one to three inches long, and two or three lines thick, ending abruptly, and sending forth numerous slender fibres of the same color. The stem is about a foot high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are bright green, and somewhat pubescent on their upper surface. The flowers are yellow.

This plant is a native of the mountainous districts of Europe and Siberia, and is found,

¹The French Codex contains a formula for a Compound Syrup of Horse-radish (*Syrup Antiscorbutique*), as follows: Scurvy-grass, water-cress, horse-radish (root), all fresh, of each, 100 parts, buckbean (marsh trefol), dried, 10 parts, bitter orange peel 20 parts, cinnamon 5 parts, white wine 400 parts, sugar 500 parts. Thoroughly contuse and comminute the solid ingredients, macerate for 48 hours with the wine, and distill off 100 parts. Express and strain the residue from the distillation, clarify the liquid with white of eggs, and strain; add 300 parts sugar, and make into a syrup of sp. gr. 1.270 while boiling; with the rest of the sugar and sufficient water make a thick syrup, mix this with the other syrup, allow to cool, then add the distilled essence. *Iodized Syrup of Horse-radish* may be made by adding one part of tincture of iodine to ninety-nine parts of the compound syrup above.

according to Nuttall, in the northern regions of this country, west of the Mississippi. It has been introduced into England, and might no doubt be cultivated in the United States. The flowers, leaves, and root are employed; but the flowers only are official in the U. S. P. (8th Rev.).

Properties.—The whole plant, when fresh, has a strong, disagreeable odor, which is apt to excite sneezing, and is diminished by drying. The taste is acrid, bitterish, and durable. The dried rhizome is cylindrical, contorted, and marked by scars from the insertion of the leaves. Water extracts its virtues. The Pharmacopœia thus describes the flowers:

"Subglobular, about 2 Cm. long; involucre campanulate-turbinate; bracts in 1 to 2 ranks, oblong, dark green, pubescent; receptacle slightly convex, deeply pitted, densely short-hairy; rays about 16, bright yellow, the ligulate portion 2 to 2.5 Cm. long, nearly 6 Mm. broad, 3-toothed, 7- to 9-nerved, pistillate; disk flowers perfect, 5-toothed, of a deeper yellow, their akenes nearly 6 Mm. long, slender, tapering sharply to the base, flattened, 5-ribbed, pubescent, the pappus nearly a half longer than the akene, of a single circle of nearly white barbelate bristles; odor characteristic and agreeable; taste bitter." *U. S.*

The U. S. 1890 description of the rhizome was as follows:

"Rhizome about 5 Cm. [two inches] long, and 3 or 4 Mm. [one-eighth to one-sixth inch] thick; externally brown, rough from leaf-scars; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter." *U. S.* 1890.

Bastiek (*P. J.*, x. 389) separated what he believed to be an alkaloid from the flowers, to which he gave the name of *arnicine*. The *arnicin* of Walz (*N. Jahrb. Pharm.*, xiii), extracted from both the root and the flowers, is a different substance; it is an amorphous yellow mass of acrid taste, slightly soluble in water, freely in alcohol or ether, and dissolving also in alkaline solutions. It is precipitable from its alcoholic solution by tannic acid or by water. Walz assigns to *arnicin* the formula $C_{50}H_{50}O_4$; other chemists that of $C_{50}H_{50}O_6$. *Arnicin* has not been proved to be a glucoside, although it is decomposed by diluted acids. Sigel (1873) obtained from dried arnica root about $\frac{1}{2}$ per cent. of essential oil, and 1 per cent. from the fresh; the oil of the latter had a sp. gr. of 0.999 at 18° C. (64.4° F.). The oil was found to be a mixture of various bodies, the principal being the *dimethyl ether of thymohydroquinone*,

$C_{10}H_{12} \begin{cases} OCH_3 \\ OCH_3 \end{cases}$, boiling at about 235° C. (445° F.), and with this, *phloryl isobutyrate* to the extent of one-fifth of the oil, and the *methyl ether of a phlorol*. (*Pflanzenstoffe*, 2d

ed., p. 1530. See also Gildemeister and Hoffmann, *Die Aetherische Oele*, p. 900.) The water from which the oil separates contains *isobutyric acid*, probably also a little *angelic* and *formic acids*, but neither capronic nor caprylic acid, which had been pointed out by Walz. Arnica root contains *inulin*, which Dragendorff extracted from it to the extent of about 10 per cent. (*Pharmacographia*, 2d edition, p. 391.)

Uses.—Arnica is an active irritant, which is capable when taken in overdose of producing symptoms of violent toxic gastro-enteritis, with great nervous disturbance, reduction or increase of the pulse rate, and collapse. In a number of cases of severe or even fatal poisoning by it, the symptoms have been burning pains in the stomach, vomiting, choleraic diarrhœa, giddiness, intense muscular weakness, dilated pupils, finally complete insensibility and collapse. In some cases the disturbances of the gastro-intestinal canal have been absent, and the symptoms have chiefly been of cerebral origin. An ounce of the tincture (*L. L.*, Nov. 1864) has produced serious but finally not fatal symptoms.

Arnica has been used in Germany in the treatment of *palsies* and various other diseases, but we have very little positive knowledge concerning its action upon the system, and there is no sufficient reason for believing that it is valuable in the treatment of internal diseases. It is largely employed externally in the treatment of *bruises* and *sprains*, generally in the form of the tincture.

The powdered flowers and leaves are employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. They may be given in substance or infusion. The dose of the powder is from five to twenty grains (0.33 to 1.3 Gm.), frequently repeated. The infusion may be prepared by digesting an ounce of the flowers in a pint of water, of which from half a fluid-ounce to a fluidounce (15 to 30 Cc.) may be given every three hours. It should always be strained through linen, in order to separate the fine fibres, which might irritate the throat. A tincture prepared from the flowers is largely used externally in this country as a domestic remedy in *sprains*, *bruises*, etc. A tincture of the root is official in the British Pharmacopœia; this would be preferable for internal use. (See *Tinctura Arnicæ*.)

Dose, of the flowers, fifteen grains (1 Gm.).

Off. Prep.—*Tinctura Arnicæ*, *U. S.* (from flowers); *Tinctura Arnicæ*, *Br.* (from rhizome).

ARSENI IODIDUM. U. S. (Br.)

ARSENIC IODIDE [Arsenic Iodide]

(âr'se-nî I-ôd'î-dûm)

$AsI_3 = 452.10$

"It should contain not less than 82.7 percent. of iodine, and 16.3 percent. of metallic arsenic. Arsenous Iodide should be kept in amber-

colored, glass-stoppered vials, in a cool place, carefully protected from the light." *U. S.*

"Arsenious Iodide, AsI_3 , may be obtained by the direct combination of iodine and arsenium." *Br.*

Arsenii Iodidum. *Br.*; Arsenici Iodidum, *U. S.* 1870; Iodide of Arsenic, Arsenious Iodide; Iodure d'arsenic, *Fr.*; Arsenicum iodatum, Arsenik Jodür, Arsentrijodid, *G.*

This iodide was introduced into the *U. S. Pharmacopœia* for the purpose of being used in preparing the solution of arsenous and mercuric iodides. It may be made by the direct combination of its constituents, with the aid of a gentle heat, but this form readily decomposes, the iodine subliming and condensing in crystals upon the upper portion of the bottle containing it. The orange red crystalline powder now official is much more permanent.

The *U. S.* process of 1870 is as follows: "Take of Arsenic sixty grains; Iodine three hundred grains. Rub the Arsenic in a mortar until reduced to a fine powder; then add the Iodine, and rub them together until they are thoroughly mixed. Put the mixture into a small flask or a test-tube, loosely stopped, and heat it gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the iodine, which may have condensed on its surface, may be returned into the melted mass. Lastly, pour the melted iodide on a porcelain slab, and, when it is cold, break it into pieces, and keep it in a well-stopped bottle." *U. S.* 1870. J. F. Babcock (*Proc. A. Ph. A.*, 1875, p. 693) proposes to make it by placing a troyounce of iodine in a suitable vessel with 10 or 12 fluidounces of water, and passing hydrogen sulphide through until the iodine color is entirely gone; then filtering, heating the filtrate until the odor of hydrogen sulphide has been dissipated; then adding a quarter of a troyounce of arsenic trioxide, heating until dissolved, filtering, and evaporating to dryness.

Nickle's process enables the operator to obtain the salt in a crystalline condition. Arsenic and iodine in equivalent proportions are heated together with carbon disulphide in a flask, to which an upright condenser is attached, until the iodine color disappears. The solution is then evaporated to the crystallizing point.

In the *Ber. d. Chem. Ges.*, 1881, 2643, may be found a process for obtaining this salt chemically pure, by making a hot solution of arsenic trioxide in hydrochloric acid, and mixing it with a concentrated solution of potassium iodide, whereupon the triiodide separates as a crystalline powder; this may be washed with hydrochloric acid, sp. gr. 1.120, until a portion of the washings on evaporation ceases to leave a residue of potassium chloride.

Properties.—Arsenous iodide is described as "an orange-red, inodorous, crystalline powder, stable when protected from direct sunlight and kept in a cool place. Soluble, with partial de-

composition, in about 12 parts of water, and in about 28 parts of alcohol at 25°C . (77°F .); completely soluble in chloroform, carbon disulphide, or ether. No loss of iodine occurs when Arsenous Iodide is heated upon a water-bath, but at higher temperatures it completely volatilizes. When warmed with a few drops of nitric acid, brown vapors of nitrous oxide are evolved, followed by violet vapors of iodine. The aqueous solution has a yellow color, is neutral to litmus paper, and upon standing gradually decomposes into arsenous and hydriodic acids. If hydrogen sulphide T.S. be added to an aqueous solution of Arsenous Iodide acidulated with hydrochloric acid, a lemon-yellow precipitate of arsenous sulphide is produced. If 0.5 Gm. of Arsenous Iodide and 2 Gm. of sodium bicarbonate be dissolved in 50 Cc. of water, not less than 21.9 Cc. of tenth-normal iodine V.S. should be required to impart a slight yellow tint to the solution." *U. S.* It has a tendency to decompose even at ordinary temperatures, iodine separating and volatilizing, oxygen being absorbed and arsenic trioxide formed.

Uses.—Following the suggestion of Biett arsenous iodide has been somewhat extensively used in the treatment of *lupus* and other skin conditions in which a powerful stimulant is desired; Biett employed the ointment of the strength of three grains to the ounce. The iodide has also been given internally as an alternative, in *cancer*, in *scrofula*, *lepra*, etc., and probably does not differ in its action from other preparations of arsenic. In large doses it acts as a violent gastro-intestinal irritant and poison.

Dose, one-tenth of a grain (0.006 Gm.).

Off. Prep.—Liquor Arseni et Hydrargyri Iodidi, *U. S.* (*Br.*)

ARSENI TRIOXIDUM. *U. S.* (*Br.*)

ARSENIC TRIOXIDE [*Acidum Arsenosum*, *Pharm.* 1890, Arsenous Acid, Arsenous Anhydride, Arsenous Oxide, White Arsenic]

(är'se-ni trī-ōx'ī-dūm)

"It should contain not less than 99.8 percent. of pure Arsenic Trioxide." *U. S.* "Arsenious Anhydride, or arsenious oxide, As_2O_3 , is obtained by roasting certain arsenical ores." *Br.*

Acidum Arsenosum. *Br.*; Arsenious Acid, Arsenicum Album, *Ed.*; Arsenious Oxide, Arsenic Anhydride; Acide arsénieux, *Fr.* *Od.*; Arsenic blanc, Fleurs d'arsenic, *Fr.*; Acidum Arsenicosum, *P. G.*; Arsenigesaur, Arsenichte Saure, Weisses Arsenik, *G.*; Anidride arseniosa, Acido arsenioso, Arsenico bianco, *It.*; Anhidrido arsenioso, Arsenico bianco, *Sp.*; Arsenik, *Dan.*, *Swed.*, *Pol.*

Arsenic trioxide is prepared in Bohemia and Saxony, where it is procured on a large scale as a collateral product during the smelting of cobalt ores, which are almost invariably accompanied by arsenic, and in England from the mineral *arsenopyrite*, also called *mispickel* or

arsenical iron, which is associated with the ores of tin and copper. The German process is that usually quoted as the older and better known. According to this, the ores are roasted in reverberatory furnaces with long horizontal flues. The arsenic is converted by combustion into arsenic trioxide, which rises in vapor and condenses on the sides of the flues. In this state it is impure, and requires a second sublimation, which is performed in cast iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenic trioxide is thrown in through the opening, which is immediately stopped. This portion being sublimed, a second portion is introduced in a similar manner. Finally, the vessels are allowed to cool; and upon removing the heads the purified oxide is found attached to them, in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken into fragments of a convenient size, and thus enter commerce. The arsenic trioxide so obtained is generally packed in casks, containing from two to five hundred pounds, and is shipped principally from the ports of Hamburg and Bremen. The English process differs somewhat in its details, and essentially in its final product, which is fine and crystalline rather than amorphous. In this process the crude arsenic of the first sublimation is refined by introducing it into another furnace or series of furnaces, where it is again volatilized by the heat. When it condenses in the long series of chambers through which the vapors are carried, it is, if the process be fully successful, in the form of a perfectly white crystalline solid, which needs only to be ground and packed into kegs to be made ready for the market. The unground arsenic is, as stated, all in the *crystalline* condition, the temperature of the chambers being too low to permit the formation of the glassy variety.

Properties.—Arsenic trioxide is entirely volatilized by heat. As the German make of arsenic occurs in commerce, it is in masses, with a vitreous fracture, and of a milk-white color externally, but, internally, often perfectly transparent. As first sublimed, the whole mass is transparent; but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. This change has not been well explained, but probably depends upon the absorption of moisture, causing a gradual passage of the acid from the amorphous to the crystalline state. (Pereira.) Hence the masses "usually present a stratified appearance, caused by the presence, in separate layers, of the crystalline and opaque and of the amorphous and vitreous allotropic modifications of arsenious anhydride." *Br. The U. S. Pharmacopœia* (8th Rev.) describes arsenic trioxide as follows: "A heavy solid occurring either as an opaque, white powder, or

in irregular masses of two varieties: one, amorphous, transparent, and colorless, like glass; the other, crystalline, opaque, and white, resembling porcelain. Frequently the same piece has an opaque, white, outer crust enclosing the glassy variety. Contact with moist air gradually changes the glassy into the white, opaque variety. Both are odorless and tasteless." *U. S.* According to Guibourt, the sp. gr. of the transparent variety is 3.73, of the opaque 3.69. The experiments, however, of J. K. Mitchell and Durand make the density of the former variety from 3.208 to 3.333. The English make of arsenic is always powdered, and, under a lens, is seen to consist of small crystals perfect in form, or of small fragments of larger crystals. In a poisoning case in 1880 (State of Conn. vs. Hayden) much was made to hinge upon the differences observed between this crystalline English arsenic and the commoner amorphous or German arsenic. (*Microscop. Exam. of Samples of Commercial Arsenic*, E. S. Dana. F. D. Linn & Co., Publishers, Jersey City, 1880.) As it occurs in commerce for medicinal use, it is often in the form of a white powder, almost as fine as flour. In this state it is sometimes adulterated with powdered lime or chalk, or calcium sulphate or arsenite, a fraud which is very easily detected by exposing the powder to a heat sufficient to evaporate the arsenic trioxide, when these impurities will be left behind. In consequence of the liability of the oxide to contain impurities when in powder, it was directed in the *U. S. Pharmacopœia* of 1870 to be kept in masses, so that the apothecary may powder it for himself as it is wanted. It has been erroneously stated to have an acrid taste. Christison asserts that it possesses hardly any taste, inasmuch as it produces merely a faint sweetish impression on the palate. In strong hot solution, it has an austere taste, most nearly resembling that of zinc sulphate. (Mitchell and Durand.) It has no odor, even in vapor; but when thrown on ignited charcoal it emits a garlicky odor, in consequence of its deoxidation, and the volatilization of the reduced metal. Its point of sublimation, according to Berzelius, is at an incipient red heat; but, according to Mitchell and Durand, it is lower than that of metallic arsenic, being only 218° C. (425° F.). In the *British Pharmacopœia* it is said to be entirely volatilized at a temperature not exceeding 204.4° C. (400° F.). Taylor gives the subliming point at 188° C. (370° F.); Wm. A. Guy states that arsenic trioxide rises in vapor at about 138° C. (280° F.) (*P. J.*, Feb. 1863). When slowly sublimed it condenses in regular octahedral crystals of a sparkling lustre. It may also be obtained crystallized in fine octahedra by the slow cooling of a solution of the oxide in boiling diluted hydrochloric acid. (*J. P. C.*, 1873, p. 246.) "0.25 gramme, dissolved quickly in boiling water with five times its weight of sodium bicarbonate, should, after the cooled solution is well shaken with three successive drops of hydrochloric acid,

discharge the color of 50.8 to 50.9 cubic centimetres of the volumetric solution of iodine." Br.

"In cold water both varieties dissolve very slowly, the degree of solubility varying according to conditions and time, the glassy variety requiring about 30, the porcelain-like or crystalline powder about 100 parts of water at 25° C. (77° F.). Both are slowly but completely soluble in 15 parts of boiling water. In alcohol, Arsenic Trioxide is but sparingly soluble, but it is soluble in about 5 parts of glycerin. Oil of turpentine dissolves only the glassy variety. Both varieties are freely soluble in hydrochloric acid, and in solutions of alkali hydroxides and carbonates." U. S. "It is soluble in 100 parts of cold water, in 10 parts of boiling water, and in 5 parts of glycerin; it is moderately soluble in solutions of alkaline hydroxides and carbonates, in hydrochloric acid, and in mixtures of that acid and water." Br. The following is given on the authority of Bussy. The transparent variety dissolves much more rapidly than the opaque. By prolonged ebullition with water, the opaque variety attains the same solubility as the transparent, and may be supposed to be converted into the latter. Thus, at the boiling temperature, a pint of water dissolves 807 grains of either variety. The transparent variety, in cold saturated solution, gradually lessens in solubility, until it reaches the solubility of the opaque, no doubt in consequence of being changed into the latter. Pulverization lessens the solubility of the transparent variety, without affecting that of the opaque. The mixture of the two varieties of the oxide in the same solution serves to explain the anomalies heretofore observed in its solubility. (J. P. C., Nov. 1847).¹ "When slowly heated in a test-tube, Arsenic Trioxide yields a sublimate of minute, brilliant, transparent, octahedral crystals. When heated rapidly to about 200° C. (392° F.), the amorphous variety fuses, then sublimes, while the crystalline variety sublimes without fusing; no residue should remain after sublimation. When covered with charcoal in an ignition-tube, and strongly heated, Arsenic Trioxide is deoxidized, and metallic arsenic is deposited on the cooler portion of the tube as a mirror having a metallic lustre. Cupric ammonium sulphate T.S. produces in an aqueous solution a bright green precipitate. If the green precipitate be dissolved in ammonia water, a deep blue-colored solution should be produced. An aqueous solution of Arsenic Trioxide has a faintly acid reaction upon blue litmus paper. Silver ammonium

nitrate T.S. produces in an aqueous solution a lemon-yellow precipitate, which dissolves on the addition of ammonia water; when this solution is heated, metallic silver is deposited (distinction from arsenic acid.) Hydrogen sulphide T.S. colors a solution of Arsenic Trioxide yellow; if a few drops of hydrochloric acid be added, it precipitates lemon-yellow arsenic trisulphide, which should be completely soluble in ammonium carbonate T. S. (absence of *antimony*, *tin*, and *cadmium*). When Arsenic Trioxide is carefully heated in a dry test-tube of hard glass, it should sublime without leaving a residue, and the sublimate should not at first show a yellow color (absence of *non-volatile matter* and of *arsenous sulphide*). If 1 Gm. of Arsenic Trioxide be dissolved in 10 Cc. of ammonia water, with the aid of a gentle heat, a colorless solution should be produced. If 0.1 Gm. of Arsenic Trioxide be dissolved, together with 1 Gm. of sodium bicarbonate, in 20 Cc. of water, by the aid of a gentle heat, it should decolorize not less than 20.3 (20.32) Cc. of tenth-normal iodine V.S. (corresponding to at least 99.8 percent. of pure Arsenic Trioxide." U. S. "Its aqueous solution, which is odorless, tasteless, and faintly acid to *litmus*, gives with *solution of silver ammonio-nitrate* a canary-yellow precipitate readily dissolved by *solution of ammonia* and by *nitric acid*. Sprinkled on ignited charcoal, it emits an alliaceous odor. It is volatilized at 400° F. (204.4° C.). . . It should yield no characteristic reaction with the tests for lead, cadmium, antimony, tin, or sulphides. It should dissolve completely in *solution of ammonia*, and the resulting liquid when diluted with an equal volume of *water* and acidulated with *hydrochloric acid* should not have a yellow color (absence of *arsenious sulphide*)." Br.

Uses.—The official preparations of arsenic are all of them, when in sufficient concentration, violent irritants or escharotics. Taken internally in sufficient dose they are exceedingly poisonous to both man and the lower animals. When properly administered they are alteratives, affecting in some unknown way the nutrition, especially of the nervous system. They are often of service in simple *nervous debility*, but are especially useful in *chorea* and in *chronic malaria*. When given for their tonic effect only, they should be used in doses so small as not to cause any general symptoms; but when a specific action, as in *chorea*, is desired, it is proper to begin with small doses and rapidly increase them until the limit of tolerance is reached. Not rarely, such doses produce gastro-intestinal irritation, especially pain and diarrhoea. To avoid this as much as possible, the remedy should be given after meals. When either gastro-intestinal irritation or the more peculiar effects of arsenic are caused, the dose should at once be lessened. The specific symptoms of *arsenicalism* are a general disposition to oedema, especially of the face and eyelids, a feeling of stiffness in these parts, itching of the skin, tenderness of the mouth, loss of

¹ Experiments of M. L. A. Buchner on the solubility of arsenic trioxide in its various forms gave the following results. A liter of water saturated at 15° C. with crystallized arsenic trioxide contains gr. 2.821; with the amorphous and vitreous variety, gr. 9.306; while the same solutions, made by boiling and then allowed to cool for 24 hours, down to 15° C. contain of the crystallized oxide gr. 27.839 per liter, and of the amorphous and vitreous, gr. 34.056 per liter. These results serve to confirm those obtained by Bussy which are referred to in the text. (J. P. C., 1873, p. 247.)

appetite, and uneasiness and sickness of the stomach. The peculiar swelling produced is called *œdema arsenicalis*. In some instances the internal use of arsenic causes a rash not unlike that of measles, and, as in that affection, attended with catarrhal symptoms. (Tilbury Fox, *M. T. G.*, March, 1868.) Sometimes salivation is produced, and occasionally the hair and nails fall off. It is stated by Charcot that he has seen, in two cases, decided anaphrodisiac effects from the prolonged use of arsenic, which disappeared several months after its discontinuance, and in one instance returned upon its resumption. (*Ann. Thé.*, 1865, p. 267.)

Arsenic trioxide has been exhibited in a great variety of diseases, the principal of which are *scirrhus* and *cancer*, especially cancer of the lip; *anomalous ulcers*; various *cutaneous diseases*; *intermittent fever*; *chorea*; *chronic rheumatism*, particularly those forms of it attended with pains in the bones; *rheumatic gout*; diseases of the bones, especially *nodes*, and firm swellings with deformity of the small joints of the hands; *chronic syphilitic affections*; *frontal neuralgia*; *hemicrania*; *intermittent neuralgic pains* of the stomach and bowels. In intermittent fever it is inferior only to cinchona bark and its alkaloïds; and probably no remedy surpasses or even equals it in *rheumatic gout*. In cutaneous affections, especially those of a scaly character, as *lepra* and *psoriasis*, it is an invaluable remedy. There would seem to be no objection against the very protracted use of this remedy in disease. Many years since, Tschudi drew attention to the so-called "*arsenic-eaters*" of Styria and the Tyrol: The habits of these people have been grossly exaggerated by some, while by others their existence has been denied, but the truth is that among the lower orders in the countries mentioned, there are many persons who habitually take small amounts of the poison. According to the report of a government commission, the dose of 0.62 grain is rarely exceeded. The "*ratsbane-eaters*" are said not to suffer in their health, and to be unusually strong and vigorous people.

The external application of arsenic has been principally restricted to *cancer*, and anomalous and malignant ulcers, especially of the kind denominated *noli me tangere*. Dupuytren used with advantage a powder composed of one part of arsenic trioxide and twenty-four parts of calomel, as a topical application to *herpes exedens*, and to the foul *ulcers* occurring after mercurial treatment.

Arsenic is the chief ingredient in nearly all the empirical remedies for the cure of *cancer* by external application. *Plunket's caustic*, a remedy of this kind of great celebrity, consisted of the *Ranunculus acris* and *Ranunculus flammula*, each an ounce, bruised and mixed with a drachm of arsenic trioxide and one hundred grains of sulphur. The whole was beaten into a paste, formed into balls, and dried in the sun. When used these balls were rubbed up with yolk of egg, and spread on pig's bladder.

The use of the vegetable matter is to act upon the cuticle, for, unless this is done, the arsenic will not act. In *onychchia maligna*, Luke of London, regarded an ointment composed of two grains of arsenic trioxide and an ounce of spermaceti ointment as almost a specific. (Pereira, *Mat. Med.*)

In Paris, an *arsenical paste* of the following composition has been used as an application to malignant *ulcers*:—red sulphide of mercury 70 parts; dragon's blood 22 parts; arsenic trioxide 8 parts. It is applied, made up into a paste with water. Pain produced by this composition is very severe, and its application dangerous. The *arsenical paste* of Frère Côme has been applied advantageously by Biett to the ulcerated surfaces in *yaws*. The precaution was used of not applying it, at one time, over a surface larger than that of half a dollar. This paste is made by mixing water with a powder consisting of ten grains of arsenic trioxide, forty grains of red sulphide of mercury, and ten grains of powdered animal charcoal. The practice of sprinkling unmixed arsenic trioxide on ulcers is fraught with the greatest danger; S. Cooper characterizes it as a murderous practice.

Febure's remedy for cancer consisted of ten grains of arsenic trioxide, dissolved in a pint of distilled water, to which were added an ounce of extract of conium, three fluidounces of solution of lead subacetate, and a fluidrachm of tincture of opium. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenic trioxide two grains, rhubarb half an ounce, syrup of chicory q. s., distilled water sufficient to make a pint. Of this mixture, a tablespoonful, containing about the sixteenth of a grain of the oxide, was given every night and morning. The dose was gradually increased to six tablespoonfuls.

Arsenic trioxide may be given in doses of from one-fiftieth to one-twentieth of a grain (0.001 to 0.003 Gm.), three times a day, in the form of pill. It is often combined with opium, which enables the stomach to bear the medicine better. The *Asiatic pills*, so called, consist of arsenic trioxide and black pepper, in the proportion of 1 part of the former to 80 parts of the latter. A preparation much used on the continent of Europe is *Boudin's solution*, which is simply an aqueous solution of arsenic trioxide with the addition of wine, and is made by boiling one gramme (15.4 grains) of the oxide with one liter (2.1 pints) of distilled water till entirely dissolved, then cooling, filtering, adding enough distilled water to supply the loss, and finally mixing with one liter of white wine. Of this solution a fluidounce contains about one-quarter of a grain of arsenic trioxide.

Dose, of arsenic trioxide, one fiftieth to one twentieth of a grain (0.001 to 0.003 Gm.).

Properties of Arsenic Trioxide as a Poison.—Arsenic trioxide, in an overdose, whether internally or externally, acts with very great energy, and generally destroys life in a short time; but in rare instances no well-marked symptoms

have been developed until eight or nine hours after the ingestion of the poison. Edward Hartshorne relates a case of recovery in which at least a drachm of arsenic trioxide had been swallowed, and where the symptoms of poisoning were delayed for sixteen hours. (*Med. Examiner*, 1855, p. 707.) The symptoms produced by the poison are—an austere taste; fetid state of the mouth; frequent ptyalism; continual hawking; constriction of the pharynx and œsophagus; the sensation of the teeth being on edge; hicough; nausea; anxiety; frequent sinkings; burning pain at the præcordia; inflammation of the lips, tongue, palate, throat, bronchi, and œsophagus; irritable stomach, so as not to be able to support the blandest drinks; vomiting of matters, sometimes brown, at other times bloody; profuse serous or bloody stools; small, frequent, and irregular pulse, but occasionally slow and unequal; palpitations; syncope; insatiable thirst; burning heat over the whole body, or a sensation of icy coldness; difficult respiration; cold sweats; suppression of urine, or scanty, red, bloody, and sometimes albuminous urine; change in the countenance; a livid circle around the eyelids; swelling and itching of the body; livid spots over the surface, and occasionally a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium, convulsions, often accompanied with insupportable priapism; falling off of the hair, detachment of the cuticle, etc. In some cases there is inflammation with burning pain in the urino-genital organs. It is very rare to observe all these symptoms in the same individual. Sometimes, indeed, they are nearly all wanting, death taking place without any pain or prominent symptoms. Occasionally the phenomena have a perfect resemblance to those of Asiatic cholera in the stage of collapse. In rare cases stupor is a very prominent symptom and the diarrhœa may not be pronounced. After death, the morbid appearances are various. In some instances no vestige of lesion can be discovered. The appearances however, in the generality of cases, are the following: the mouth, stomach, and intestines are inflamed; the stomach and duodenum exhibit spots resembling eschars, and perforations of all their coats; and the villous coat of the former is in a manner destroyed, and reduced to the consistence of a reddish-brown pulp. Wide-spread fatty degeneration has also been noted. In cases of recovery, it has been a question how long it takes for the poison to be eliminated from the system. In an instance reported by D. MacLagan, in which about two drachms of the poison had been swallowed, and in which magnesia was used successfully as an antidote, arsenic was detected in the urine by Marsh's test as late as the twentieth day.

A chronic form of arsenical poisoning, yet sometimes serious in its consequences, has resulted in many instances from the inhalation of the air of apartments lined with green wall paper, which owes its color to copper arsenite,

and from which a fine poisonous dust sometimes escapes when the paper has not been well prepared. (See *Chem. News*, March 24, 1860.) The burning of green tapers is sometimes attended with an arsenical odor, and chemical examination has shown that, in relatively rare instances, they sometimes contain arsenic trioxide in injurious quantities. (*L. L.*, 1873, p. 715.) Death has also resulted, in more than one instance, from working in the manufacture of green artificial leaves. (*Chem. News*, Nov. 30, 1861.) Ulceration of the anus has resulted from the habitual use of green paper. In 1900, there occurred an epidemic of chronic arsenic poisoning in Manchester, England, which arose from beer prepared from arsenical glucose. The symptoms of chronic arsenic poisoning are too protean to permit of detailed description. The most important are: peripheral neuritis, inflammation or overgrowth of skin and dermal appendages with irritation at the point of entrance; thus when from inhalation of arsenical dust there is laryngitis and bronchitis; when it finds entrance through the alimentary canal, gastric disturbance and diarrhœa.

In view of the numerous accidents and crimes caused by the use of arsenic trioxide, its sale should be regulated by law in all the States of the Union. In 1851 an act for this purpose in England was passed by the British Parliament.

There can be no doubt that, when applied to any ulcerated surface, arsenic may be absorbed with fatal result; death has indeed occurred in a number of cases from the use of arsenic as an escharotic to tumors, cancerous ulcers, etc. As indicated by Blackader, absorption is less likely to follow the use of large than of small quantities, the larger amount probably killing the part to which it is applied, and thereby preventing absorption. If this dangerous caustic be used at all, it should be in accordance with these facts. Harles's observations also seem to show that when the surface is that of a chronic ulcer, either simple or malignant, absorption is less prone to occur than from a fresh wound.

Treatment of Poisoning by Arsenic Trioxide. If the antidote (see *Ferri Hydroxidum cum Magnesi Oxido*) be not directly at hand, free vomiting should be induced by the finger, the feather part of a quill, and the administration of an emetic; or the poison may be removed by the use of the stomach tube. Demulcent drinks should be freely given, such as milk, white of eggs and water, or flour and water, which serve to encourage the vomiting and to envelop the poison.

The antidote having been faithfully applied, the subsequent treatment consists in the administration of mucilaginous drinks, and the treatment of symptoms as they arise. Convalescence is generally long and distressing; usually dyspeptic symptoms mark the presence of gastrointestinal inflammation or even ulceration, while not rarely violent neuralgic pains, with loss of power, wasting of the muscle, and other trophic changes, show that a peripheral neuritis has

been produced; hence it is of the greatest importance to attend to the diet, which should consist exclusively of milk, gruel, cream, rice, and similar bland articles.

The antidote above referred to is *ferrie hydroxide* or preferably *ferrie hydroxide with magnesium oxide*, in the *moist or pulpy* state. As soon as it is ready, it must be given in doses of a tablespoonful to an adult, of a dessertspoonful to a child, every five or ten minutes, until the urgent symptoms are relieved. It is calculated that the quantity taken should be at least twelve times the supposed amount of the poison swallowed; but, as the antidote is perfectly innocent, it is prudent to give it in larger quantities. According to the experiments of E. Riegel, one part of arsenic trioxide in solution is so fully precipitated by ten parts of the dry oxide, that, after its action, not a trace of the poison can be detected, even by Marsh's test. Its efficacy is, of course, greater, the sooner it is administered after the ingestion of the poison; but even after delay its use will prove advantageous, so long as any portion of the poison still remains in the stomach. Ferrie hydroxide acts by producing with the poison, by a transfer of oxygen from the oxide to the acid, an insoluble, and therefore inert, ferrous arsenate:

This antidote was discovered by Bunsen and Berthold of Göttingen, in 1834; and its efficacy has been abundantly confirmed by experiments on inferior animals, and by its successful application to numerous cases of poisoning in the human subject. Various observations have been made as to the best forms of the ferrie hydroxide for use, but as long ago as 1842 Wm. Procter (*A. J. P.*, xiv. 29) proved that the hydroxide gradually decreases in its power of neutralizing arsenic trioxide the longer it is kept, and that this decrease in power is more rapid when it is mixed with much water than when in the form of a thick magma. The cause of this diminution of neutralizing power, by being kept, is explained by the experiments of Wittstein. This chemist found that ferrie hydroxide, recently precipitated, dissolves readily in acetic and other vegetable acids in the cold, but becomes nearly insoluble when kept for some time under water. It should be an invariable rule to prepare the antidote at the time it is wanted from materials always kept at hand. A very efficient antidote may be made by precipitating the tincture of ferrie chloride with sodium bicarbonate.

Dialyzed iron has been frequently suggested as an antidote for arsenic (*P. M. T.*, Dec. 8, 1877; *A. J. P.*, Jan. 1878), especially if its administration be followed by a dose of common salt, which precipitates the ferrie hydroxide in the stomach; but E. Hirschsohn (Dorpat, Russia) cautions against the use of dialyzed iron, because his experiments show that the resulting combination parts with its arsenic in the presence of acids much more readily than

does the *Antidotum Arsenici* of the Russian Pharmacopœia—made by diluting one ounce of solution of ferrie sulphate with four fluidounces of water, then adding a mixture of three drachms of calcined magnesia with four fluidounces of water. (See *Ferri Hydroxidum cum Magnesii Oxido*.)

Köhler of Halle, believes saccharine oxide of iron in solution is preferable to all other preparations, in poisoning by arsenic trioxide. This forms, like the hydrated powder, an insoluble compound with the acid. He bases his opinion upon experiments with the lower animals, and gives the details of a case in which it proved successful in the human subject after the swallowing of more than half a drachm of the oxide in powder. He gave a large teaspoonful of the saccharine oxide with a drachm of water immediately afterwards, which was repeated every 15 minutes for two hours, followed by an emetic dose of ipecacuanha, and then repeated every half hour. The patient recovered. (*B. F. M. R.*, 1870.)

Bussy has proposed light magnesia, or the kind which has not been too strongly calcined, as well as recently precipitated gelatinous magnesia, as an antidote for arsenic trioxide; and a case is given by him in which it appeared to prove efficacious. (*J. P. C.*, x. 81.) The dense kind has very little efficacy. Christison saw a case in which this antidote seemed very serviceable. A successful case is also reported by Cadet de Gassicourt (*J. P. C.*, Mars, 1848), and another by E. Bissell of Norwalk, Conn. (*Am. J. M. S.*, July, 1848). For the full precipitation of arsenic trioxide, eighteen times its weight of anhydrous magnesia are required. (E. Riegel.) Like the ferrie hydroxide, the magnesia antidote should be made extemporaneously by mixing diluted solution of ferrie sulphate with magnesia mixture. Schroff has made some experiments on rabbits to determine the comparative efficacy, as antidotes, of the ferrie hydroxide and magnesia, and gives the preference to the latter. The hydrated magnesia is best prepared extemporaneously by quickly forming a solution of magnesium sulphate, and precipitating this by ammonia water, which is preferable to potassium hydroxide, as any portion of the latter, remaining in the preparation, might act injuriously by favoring the solubility of the arsenic trioxide. Notwithstanding these statements, however, it is asserted by T. and H. Smith of Edinburgh, on the basis of experiment, that magnesia is incapable of neutralizing arsenic trioxide, and is useless as an antidote (*P. J.*, 1865, p. 144), and that it should not be depended upon when the ferruginous antidote is attainable. The best antidote known is the combination of ferrie hydroxide with magnesium oxide, now recognized by the U. S. Pharm.

Reagents for detecting Arsenic Trioxide. As arsenic is so frequently employed for criminal purposes, it becomes important to detect its presence in medico-legal investigations.

Having obtained general indications of the presence of arsenic, the first step is to separate the organic matters. In a communication to the Paris Academy, Blondlot of Nancy, asserted, as the result of numerous experiments, that the smallest quantity of oily or fatty matter has the effect of diminishing, even to one-twentieth, the solubility of arsenic trioxide, and consequently of very much increasing the difficulty of detecting it. (See *A. J. P.*, 1860, p. 220.)

The following are the directions given by Wormley (*Micro-Chemistry of Poisons*, 2d ed., p. 299) for separating the organic principles. After the addition of water, if necessary, the mass is intimately mixed with about one-eighth of its volume of pure hydrochloric acid, and maintained at near the boiling temperature until the organic solids are entirely disintegrated. The mixture is then allowed to cool, transferred to a clean muslin strainer, and the matters retained by the strainer washed with water; the strainer with its contents may be reserved for future examinations. The strained liquid is concentrated at a moderate heat if necessary, allowed to cool, and again filtered.

A given portion of the filtrate thus obtained is examined by the method of Reinsch (see page 205), successive slips of the copper being added as long as they receive a deposit. Any pieces of the metal that have thus become coated, after being thoroughly washed and dried, are heated in a suitable reduction tube, and the result examined in the usual manner. Another portion, or the whole of the remaining filtrate, may be exposed for several hours to a slow stream of the hydrogen sulphide gas, then gently warmed, and allowed to stand until the supernatant liquid has become perfectly clear. The precipitate thus produced is collected upon a small filter, washed, and, while still moist, digested with pure ammonia water, this liquid will readily dissolve any arsenic sulphide present, while the organic matter may remain undissolved. The ammoniacal solution is filtered, and the filtrate carefully evaporated at a moderate heat to dryness. Should the residue contain organic matter and only a minute quantity of the sulphide, it may require further purification before its arsenical nature can be determined.

In order to facilitate the detection of arsenic in the solid tissues, as the liver, spleen, stomach, etc., it is necessary first to destroy the animal matter, and then to dissolve out the poison. Various agencies have been resorted to for this purpose, but the method of Fresenius and Babo is generally accepted as the best. According to this, the finely divided fragments of solid matter are heated with pure hydrochloric acid, and potassium chlorate is added from time to time until the mass becomes homogeneous and of a light yellow color. It is then heated until the odor of chlorine has disappeared. After filtration any arsenic present will exist in the filtrate as arsenic acid. This is reduced

by sulphurous acid gas or a solution of sodium bisulphite, so that the arsenic is brought to the condition of arsenous acid, in which state it is more readily acted upon by hydrogen sulphide gas.

After thorough precipitation of the sulphide and purification of this precipitate by treatment with ammonia as already described, if the residue from the evaporation of the ammonia still contains organic matter mixed with the arsenous sulphide, it is best purified as follows. Treat the residue with a small quantity of concentrated nitric acid, and evaporate the mixture again to dryness, this operation with nitric acid being repeated, if necessary, until the moist residue has a yellow color. The residue is then moistened with a few drops of a concentrated solution of caustic soda, a small quantity of pure powdered sodium carbonate and sodium nitrate added, and the well mixed mass cautiously evaporated to dryness; the heat is then very gradually increased until the mass becomes colorless, when the organic matter will have been entirely destroyed. The nitric acid and the soda compounds employed should be free from chlorine, or a portion of the arsenic may be volatilized as chloride. (Wormley, *Micro-Chemistry of Poisons*, 2d ed., p. 303.)

Another method of separating arsenic in solution from organic matters, now frequently employed, is by the process of dialysis, invented by Graham. (See *Dialysis*.) By means of an instrument called the dialyzer, aqueous solutions of saline and other crystallizable substances may be separated from those not crystallizable, such as gelatinous, albuminous, mucilaginous, and amylaceous liquids, the latter refusing to pass through a diaphragm of some porous substance, which is readily permeable by the former. Thus, a circular piece of parchment paper, folded in the form of a common filter, is placed in a vessel containing distilled water; the suspected liquid, having been heated so as to effect a more complete solution of the arsenic, is poured into the filter, and the vessel set aside for twenty-four hours. At the end of this time, the crystallizable matter, including the arsenic, will have, to a great extent, passed through into the distilled water, leaving the organic matters behind, and a solution will have been obtained in a condition fit for the application of the different tests.

The passage of the arsenic through the membrane is, however, rarely a complete one, and the test cannot allow us to dispense with more thorough methods of examination.

Following up a suggestion of Clarke of Aberdeen, that arsenic might be separated by taking advantage of the volatility of its chloride, Andrew Fyfe of the same place, applied the principle to the detection of the metal when mixed with organic matter. For this purpose, he heated the arsenical liquid with sulphuric acid, free from arsenous acid, in a flask to which a bent tube and cooled receiver were adapted. When the mixture was brought to the

boiling point, a little dried sea salt was added, the receiver was connected, and the distillation continued for some time. Hydrochloric acid was evolved, which, by reacting with the arsenous acid, produced arsenic trichloride, which distilled over free from organic matter. The arsenic trichloride was then precipitated by a stream of hydrogen sulphide gas to obtain the yellow arsenic trisulphide, or subjected to the action of Marsh's test. (*Philos. Mag.*, 4th series, ii. 487.) By keeping present a larger amount of salt than can be decomposed by the sulphuric acid, the formation of sulphurous acid is avoided, and there is no danger of converting arsenous acid into the arsenic compound, as is the case in the presence of free chlorine. Arsenic acid is not converted into a volatile chloride, and would therefore escape detection in this process. Indeed, it is proposed to distinguish between arsenous and arsenic acids in mixtures by this reaction. After all the arsenous acid has been distilled off as arsenous chloride, the arsenic acid can be reduced by sulphurous acid and then distilled for itself. (*Handwörterbuch der Chem.*, i. 746.) The reduction of arsenic acid to arsenous acid is very conveniently effected, according to E. Fischer, by ferrous chloride used in connection with hydrochloric acid. (*Ber. d. Chem. Ges.*, xiii. 1778.) Penny and W. Wallace bear testimony to the value of the plan of converting the arsenic into trichloride, as a means of separating the metal from organic matter, but think it will be found more convenient to produce the trichloride by the direct agency of hydrochloric acid than by sulphuric acid and sodium chloride as recommended by Fyfe.

The method of testing for arsenic proposed by Marsh, is perhaps the best known of the arsenic tests. It consists in taking advantage of the power which nascent hydrogen possesses of decomposing the acids and arsenic, with the result of forming water and hydrogen arsenide, as illustrated by the subjoined reaction:

Any compound of arsenic other than those containing sulphur may now be added to the materials for generating hydrogen (pure diluted sulphuric acid and zinc), contained in a self-regulating generator of hydrogen. Canudas y Salva prevents the possible explosion of the apparatus, resulting from the ignition of the hydrogen before all the air has been expelled, by placing in the lateral exit tube two metallic meshes, enclosing between them very loose cotton. (*N. R.*, April, 1878.) Fresenius proposed the same years ago. If the added material contains arsenic, the nascent hydrogen will combine with the metal, and the nature of the compound gas formed may be ascertained by burning a jet of it from a fine jet-pipe connected with the generator. The flame will have a characteristic bluish-white color; and, by holding a porcelain plate against it, a thin film of metallic arsenic, forming a brownish-black stain,

will be deposited. To remove every source of fallacy it is necessary to be sure of the purity of the materials for generating the hydrogen by a preliminary trial of the gas before the suspected liquid is added, as zinc and sulphuric acid are both liable to contain arsenic. This trial is made by holding a plate against the burning hydrogen, which, if pure, will produce no stain. The pieces of zinc employed should be changed after every experiment. Magnesium or aluminum may be advantageously substituted for zinc, as they contain no arsenic, or, still better, sodium amalgam (made by adding about 5 per cent. of metallic sodium to some warmed mercury), as proposed by E. W. Davy. This can be used then in a neutral solution, the evolution of nascent hydrogen being due to the decomposition of the water by the sodium.

If the sulphuric acid used to act upon the zinc contains nitrous compounds, the liberation of arsenic may be prevented. To obviate this difficulty a solution of stannous chloride in hydrochloric acid should be added towards the end of the operation. This liberates any arsenic present because of its reducing action, and arsine will be formed from it.

Still another modification is Fleitmann's test, in which the use of zinc, magnesium, or aluminum is retained, but the development of nascent hydrogen is brought about by the addition of potassium or sodium hydroxide. Under these circumstances hydrogen arsenide is produced, but hydrogen antimonide cannot be formed. A modification of Marsh's apparatus consists in having the tube which delivers the hydrogen arsenide narrowed in several places. If, then, while the gas is passing, heat be applied a little this side of the narrowed place, the compound is decomposed and a bright mirror of metallic arsenic is deposited in the contraction. As a very small deposit can be changed subsequently into trioxide or sulphide, both of which are characteristic, this test is quite delicate.

It has been objected to Marsh's test, that antimony forms a compound with hydrogen, very similar to hydrogen arsenide, both in the color of its flame, and in the metallic spot which it deposits during combustion on cold surfaces. Still, the two metals may be distinguished by acting on the metallic spot with a drop or two of fuming nitric acid, with the aid of heat. Arsenic will thus be converted into soluble arsenic acid (which forms a brick-red precipitate on the addition of silver nitrate solution) while antimony is changed into insoluble antimonic acid. Another way of distinguishing them is to apply to the stain a solution of sodium hypochlorite, which instantly dissolves the arsenical spot, without affecting that of antimony, or solution of stannous chloride, which has no action on metallic arsenic, while it dissolves slowly but completely the antimony stain. (Blyth, *Poisons, Effects and Detection*, p. 526.) Sodium nitroprusside also,

while it has no effect upon arsenic spots, will dissolve those of antimony completely and easily. (*Handwörterbuch der Chem.*, i. 757.) In case the metallic mirror is obtained in the tube by Berzelius's modification of Marsh's test, a stream of hydrogen sulphide may be passed, while immediately behind the stain a gentle heat is applied. Arsenic is changed thereby to yellow sulphide, while antimony produces an orange or black sulphide; if dry hydrochloric acid gas is now transmitted, the arsenical sulphide is unchanged, while antimony sulphide is converted into chloride of antimony, which volatilizes without the application of heat. (Blyth, *loc. cit.*) Ammonium sulphide dissolves the arsenical spot with difficulty, leaving on evaporation a yellow stain; it readily dissolves the antimonial, and yields an orange-red spot. Marsh's test may be still further modified as proposed by Lassaigne. The current of hydrogen arsenide is conducted into solution of silver nitrate, when it is decomposed according to the reaction:

Here arsenous acid is formed, which goes into solution, and metallic silver separates. Hydrogen antimonide passed into silver nitrate solution produces a black precipitate of silver antimonide, in which all the antimony is contained.

Gutzeit's modification of this test is to carry out the reaction in a test tube, which is then covered by paper moistened with silver nitrate. A black stain indicates the presence of arsenic. Ritser (*Ph. Ztg.*, 1889, 368) has increased the delicacy of this by using ammoniacal silver nitrate. It is asserted that 0.0005 milligramme of arsenous oxide will cause a brown stain.

The Modified Gutzeit's Test (U. S. Pharm., 8th Rev., see PART III, No. 17), in testing for the presence of traces of arsenical impurity in official chemicals, uses paper which has been moistened with alcoholic mercuric chloride solution and dried, as the cap at the end of the test tube. Zinc and hydrochloric acid, previously tested for purity in a blank experiment, are used, and the solution supposed to contain arsenic is heated with a solution of sulphurous acid to reduce the arsenic compound to the condition of arsenous acid, and any excess of sulphur dioxide boiled off. If, under these circumstances, the hydrogen evolved contains hydrogen arsenide, a distinct yellow or orange spot will be formed upon the mercuric chloride paper cap. One part of arsenic in 100,000 is readily recognized by the test. Antimony, under the same conditions, produces a dark gray to brownish-black coloration, and sulphur compounds a black stain. Bettendorf's test, as used in the *Pharm. Germ.*, ed. iv., depends on the fact that a concentrated solution of stannous chloride will cause the separation of metallic arsenic from arsenous acid even in the cold, and from arsenic acid on heating. As adopted by the U. S. Pharmacopœia (8th Rev.), fifteen

minutes heating of the test tube containing the mixture, by immersion in a bath of boiling water, followed by standing for one hour, is prescribed. In the absence of arsenic, no trace of brownish color should appear.

Reinsch has proposed a method of detecting arsenic in organic liquids, which is extremely delicate and at the same time has the merits of facility and celerity. It consists in acidulating the suspected liquid with hydrochloric acid, which converts the arsenous acid into the trichloride, and boiling in it, for ten minutes, a slip of copper foil, on which the arsenic is deposited as an alloy consisting of one part arsenic to five parts copper; and then separating it in the state of arsenous acid, by subjecting the copper, cut into small pieces, to a low red heat in the bottom of a small glass tube. The peculiar crystalline appearance of arsenous acid, mentioned in the preceding page, is conclusive of its presence, and, besides, if collected and dissolved in water it will answer to the ordinary tests for the poison. The merit of Reinsch's procedure is not so much that it gives a characteristic deposit on the copper—for bismuth, tin, zinc, and antimony also give deposits—as that the copper collects all the arsenic from the organic liquid, and presents it in a convenient form for applying the liquid and subliming tests. But Reinsch's method is not without its fallacies. Thus, it has been ascertained that the presence of a nitrate or chlorate in the suspected material prevents the characteristic action of the arsenic on the copper until the whole of these substances have been consumed by reaction with the metal. Besides, both hydrochloric acid and copper are liable to contain arsenic, and therefore to afford fallacious results. This, however, is less true of the hydrochloric acid prepared in this country than of the European, as the sulphuric acid employed in its preparation here is obtained generally from native sulphur, instead of from pyrites as abroad. Nevertheless, no conclusion from Reinsch's test can be certainly relied on unless the hydrochloric acid has been ascertained to be free from arsenic. With the copper there is less risk, as the arsenic in it can act only by solution of the copper itself, and this is known by the green color imparted to the liquid; so that, if the arsenical deposit should be produced without discoloration of the liquid, the indication of the presence of the poison may be considered as satisfactory. (Odling and Taylor.)

The compounds of arsenic and sulphur do not respond directly to the influence of nascent hydrogen, and hence cannot be indicated by the Marsh and similar tests. In such cases the test of Fresenius and von Babo is used. The suspected material, previously dried, is rubbed up thoroughly with a mixture of three parts of dry sodium carbonate and 1 part of potassium cyanide, and introduced into a small dry test tube, so as to make a layer of about one-fourth of an inch in depth. On heating the end of

the tube until the contents are fused, a ring-like mirror of metallic arsenic will form, a short distance above the heated spot.

It has been shown by Malaguti and Sarzeau that for the detection of minute quantities of arsenic in exhumed bodies the best method of proceeding is to distil the viscera with aqua regia, made by mixing one part of nitric with three of hydrochloric acid. The animal matter (the liver, for example), cut into small pieces, is dried by a gentle heat, and mixed with a quantity of the aqua regia equal to the weight of the matter before it was dried. The mixture is distilled, and the arsenic, if present, comes over in the form of the volatile trichloride, which may be converted into the trisulphide in the usual manner.

Arsenic may be detected in exhumed bodies long after death. Blondlot found it in the brain of a body that had been buried twenty years. In this case it was ascertained that no arsenic existed in the earth of the cemetery. (See *B. F. M. R.*, 1855, p. 222.) It is necessary also to be guarded against the possible presence, about the body, of metals which may contain arsenic, as, for example, brass and copper. L. A. Buchner has found, in the intestines of persons who had been poisoned with arsenic trioxide, examined some months after death, the poison in the state of yellow arsenic sulphide, into which it had been converted by the hydrogen sulphide developed by the putrefactive process that had taken place in the bowels, showing that even in poisonous doses arsenic has not always the property of preserving the body from corruption. (*Neues Repertorium*, xvii. 21.)

Dose, of arsenic trioxide, one-fiftieth to one-twentieth of a grain (0.0013 to 0.003 Gm.).

ARSENUM.

ARSENIC

(ä'r-sē-nūm)

As = 74.4

Arsenicum, *U. S.* 1870; Arsenium; Arsenic, *Fr.*; Arsen, Arsenik, *G.*; Arsenico, *It.*, *Sp.*

This metal was introduced into the *U. S.* and *Dublin Pharmacopœias* in 1850, for the purpose of being used to form arsenous iodide, and the solution of arsenous and mercuric iodide, at that time two new salts of those works. It has been rejected by the compilers of the *U. S.* and the *British Pharmacopœias*. The *Dublin College* gave the following formula:

"Take the White Oxide of Arsenic of Commerce two drachms [*Dub. weight*]. Place the Oxide at the sealed end of a hard German glass tube, of about half an inch in diameter and eighteen inches long, and, having covered it with about eight inches of dry and coarsely

pulverized charcoal, and raised the portion of the tube containing the charcoal to a red heat, let a few ignited coals be placed beneath the Oxide, so as to effect its slow sublimation. When this has been accomplished, the metallic arsenic will be found attached to the interior of the tube at its distant or cool extremity.

"In conducting this process, the furnace used in the performance of an organic analysis should be employed, and the fuel should be ignited charcoal. It will be proper also to connect the open extremity of the tube with a flue, for the purpose of preventing the possible escape into the apartment of arsenical vapors; and, with the view of keeping it from being plugged by the metal, to introduce occasionally into it, as the sublimation proceeds, an iron wire through a cork, fixed (but not air-tight) in its open extremity."

In the above process, the white oxide (arsenic trioxide) is reduced by the agency of ignited charcoal, which attracts the oxygen of the oxide, and revives the metal. On the large scale, metallic arsenic is generally obtained by heating arsenical pyrites (FeAs_2 , FeS_2) in earthen tubes, when the metal sublimes, and two molecules of ferrous sulphide, FeS , are left.

Properties.—Arsenic is a brittle, crystalline metal, of a steel-gray color, and possessing much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and blackish. Its texture is granular, and sometimes a little scaly. Rubbed on the hands, it communicates a peculiar odor, but it is devoid of taste. Its sp. gr. is about 5.73 (5.88). When heated to about 180°C . (356°F .) it sublimes, giving rise to white vapors having a garlicky odor.¹ An amorphous modification results from the decomposition of hydrogen arsenide by heat, the arsenic appearing as a dark brown deposit. There is also a yellow modification which is formed when arsenic vapor is strongly cooled. It resembles yellow phosphorus, as it is soluble in carbon disulphide and oxidizes in the air with luminosity. Its atomic weight is 74.4. It forms two combinations with oxygen, arsenous and arsenic oxides, As_2O_3 and As_2O_5 respectively, to each of which the corresponding acid is known, and three with sulphur, namely, the disulphide, or realgar, As_2S_2 ; the trisulphide, or orpiment, As_2S_3 , corresponding in composition to arsenous oxide; and the pentasulphide, As_2S_5 , corresponding to arsenic oxide. (See *Arseni Trioxidum*; also *Realgar* and *Orpiment* in PART II of this work.) Arsenic oxide is obtained by distilling off a mixture of twelve parts of nitric and one of hydrochloric acid from four parts of arsenic trioxide, until the whole acquires the consistence of a thin syrup. The liquid is then poured

¹ The statement that arsenic on being heated sufficiently, passes at once into the state of vapor without fusing was disproved by experiments of Dunnington and Odger, made under direction of Mallet of the *U. of Va.* They succeeded in fusing arsenic without great difficulty. (*Chem. News*, Aug. 30, 1872.)

into a porcelain dish, and evaporated at a moderate heat. Suddenly the arsenic oxide concretes into an opaque white mass, which should be transferred, while warm, to a well-stoppered bottle. Arsenic oxide is white, solid, deliquescent, and soluble in six parts of cold and two of boiling water. It forms several acids, corresponding to the several varieties of phosphoric acid, to which it bears a close analogy. With silver nitrate it gives a brick-red precipitate of silver arsenate. As a poison it is even more virulent than arsenous oxide. It consists of two atoms of arsenic and five of oxygen (As_2O_5).

The world's supply of arsenic and arsenic compounds at the present time is obtained from Germany, Spain, England and Canada, although in Montana and Washington considerable quantities of arsenic are being produced as a by-product in the smelting of copper ores. In 1903 the German production of arsenic was 2768 metric tons; that of Spain, 1088 tons; of England, 917 tons, and of Canada, 233 tons, while the United States produced 554 tons. The importations of arsenic, arsenous oxide, and arsenic sulphides into the United States for 1903 amounted to 8,357,661 lbs., valued at \$294,602.

Arsenic is much diffused. Besides being present in a great many minerals, it has been detected, in minute proportion, in the earth of cemeteries by Orfila; in certain soils and mineral waters by Walechner; in the ashes of various plants by Stein; in various mineral coals; also in the incrustation formed in the boiler of a sea-going steamer, by Daubrée. Recently it has been found in minute quantities in many plants and even in the tissues of the human body.

ASAFETIDA. U. S. (Br.)

ASAFETIDA

(äs-ä-fet'ī-dä)

"A gum-resin obtained from the root of *Ferula fetida* (Bunge) Regel, and probably other species of *Ferula* (Fam. *Umbelliferae*)." U. S. "A gum-resin obtained by incision from the root of *Ferula fetida*, Regel; and probably other species." Br.

Asafetida. Br.; Stercus Diaboli, Cibus Deorum; Gummi-resina Asafetida; Asa fetida, Asse-fétide, Assafetida, Fr.; Asa fetida, P. G.; Asant. Stinkasant, Teufelsdreck, G.; Asa fetida, It.; Asafetida, Sp.; Ungoozeh, Pers.; Hiltet, Arab.; Hing, India; Angusa-kema, Afgh.

Concerning the genus *Ferula* there has been much dispute by botanists, but at present a much wider range is given to it than formerly. H. Falconer (*Tr. Linn. Soc.*, xx. 285) separated from it the genus *Narthex*, relying chiefly upon the distinctness of the vittæ as characteristic, while Bunge separated the genus *Scorodosma* on account of the absence of vittæ. According, however, to Bentham and Hooker, the vittæ in Bunge's type specimens are no

more inconspicuous than in various other species of the genus; and, further, the vittæ vary so much that no generic character can be drawn from them. The genus *Ferula* is a very difficult one to characterize briefly, see Bentham and Hooker, *Genera Plantarum*, i. 917.

Ferula fetida, Regel, *F. Scorodosma*, Bentham and Hooker, *Scorodosma fetidum*, Bunge, *Ferula Assafetida*, L., of Boissier (*Flora Orientalis*, ii. 994), is a coarse umbelliferous plant, growing from five to seven feet high, with a large fleshy root, the crown of which is covered with coarse bristly fibres, and gives origin to large bipinnate radical leaves and a nearly naked stem which has only a few bipinnate leaves without wide sheathing petioles, and ends at the top in very numerous umbels. The flat-winged fruit have the vittæ almost obsolete. This plant was first discovered in the sandy desert near the sea of Aral, by Lehmann, in 1844. Bunge found it in Persia about twenty years later. It would seem to be native all through Afghanistan.

Ferula Assafetida, Willd., *Sp. Plant.*, i. 1413. B. & T. *Ferula Narthex*, Boiss. *Narthex Assafetida*, Falconer.—This plant, which was formerly recognized officially as a source of asafetida, was first described from actual observation by H. Falconer, who found it near Kashmir, and has long been successfully cultivated in the Edinburgh Botanical Gardens. It is distinguished from the true asafetida plant by the greater height of the stem (6 to 10 feet), and by the numerous stem leaves furnished with wide sheathing petioles. The flowers are pale yellow, and the oval fruit thin, flat, foliaceous, and reddish brown, with pronounced vittæ. It yields a milky juice having a powerful odor of asafetida.

It is possible that asafetida is obtained from various species of *Ferula*, yet the bulk of the drug probably comes from the official plant. This plant does not agree with the description given by E. Kaempfer of the plant which he observed in 1687, and to which he gave the name of *Assafetida disquinensis*, although Falconer considers the latter plant as identical with his *Narthex Assafetida*, and Borszczon, who studied *F. Scorodosma*, growing wild in the neighborhood of the Caspian Sea, believes this plant the same as that described by Kaempfer. It is very likely that the difficulty of identification is due to inaccuracies in the original figure of Kaempfer. *F. persica*, W., *F. alliacea*, Boiss., *F. Assafetida*, L., *Assafetida disquinensis*, Kaempf., *F. Narthex*, Boiss. (*Narthex Assafetida*, Falc.), have had official recognition. E. M. Holmes's discussion of the asafetida plants (*P. J.*, ser. iii. xix., 1888-9) still remains our chief source of information on the subject. *Ferula Jäschkeana*, Vatke, which has been believed to be the source of asafetida, according to E. M. Holmes, has, at least in its dried state, not the slightest odor of asafetida, and indeed yields a strongly celery-scented juice. (*P. J.*, 1894, xxv.).

The asafetida plants are indigenous to Western Afghanistan and Eastern Persia. In 1687 the collection of asafetida was witnessed by Kaempfer, whose description of the method is very similar to that given by H. W. Bellew in 1872, and by J. E. T. Aitchinson in 1884. According to Aitchinson, the high plains of Afghanistan, two to four thousand feet above the sea, are arid and bare in winter, but in the early summer are covered with a thick growth of *Ferula foetida*, *Dorema ammoniacum*, and *Ferula galbanifusa*. The great cabbage-like heads of the asafetida plant, representing the primary stage of the flower heads covered over by the stipules of its leaves, are eaten raw by the natives as a sort of green. In June the asafetida is obtained. The root stock is first laid bare to the depth of a couple of inches, those plants only which have not reached their flower bearing stage being selected. A slice is then taken from the top of the root stock, which is immediately covered with twigs and clay, forming a sort of dome, with an opening towards the north, so that the sun cannot get at the exposed root. About five or six weeks later, a thick, gummy, not milky, reddish substance found upon the exposed surface of the root in more or less irregular lumps is scraped off with a piece of iron hoop or removed with a slice of the root and at once placed in a leather bag. The asafetida is conveyed to Herat, where it is adulterated with red clay before being sent into commerce. It is brought to this country directly from India, whither it is conveyed from Bushire and down the Indus, or by the route of Great Britain. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety pounds, the latter from two hundred to four hundred pounds. Asafetida is sometimes also imported in casks.

The fruit of the asafetida is said to be sent to India, where it is highly esteemed as a medicine.

Properties.—As found in commerce, asafetida is in irregular masses, softish when not long exposed, of a yellowish or reddish-brown color externally, exhibiting when broken an irregular, whitish, somewhat shining surface, which soon becomes red on exposure, and ultimately passes into a dull yellowish-brown. This change of color is characteristic of asafetida, and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as if composed of distinct portions agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the tears are separate, though rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, sometimes larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odor, which, however, is weaker than

that of the masses. A very fine variety of asafetida is spoken of by Bellew as being procured from the leaf bud in the centre of the root. It does not come into European commerce, but is the *Kandaharee Hing* of the Indian bazaars. (*P. J.*, viii. 103.) It occurs in moist flaky pieces and tears, yielding a reddish-yellow oil on pressure, and mostly mixed with the remains of leaf buds. The ordinary asafetida of the Indian bazaars is known in the superior grade as *Hing*, in the inferior grade as *Hingra*. The odor of asafetida is alliaceous, fetid, and tenacious; the taste, bitter, acrid, and durable. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its odor and taste, particularly the former. Kaempfer assures us that one drachm of the fresh juice diffuses a more powerful odor through a close room than one hundred pounds of the drug as usually kept in the stores. The color, which is at first white, becomes pink, and finally the well known brown, on exposure. Asafetida softens by heat without melting, and is difficult of pulverization. Its sp. gr. is 1.327. (Berzelius.) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water. "The freshly fractured surface becomes greenish on the application of a few drops of a 40 percent. nitric acid solution; becoming hard and brittle by drying; odor persistent, alliaceous; taste bitter, alliaceous, and acrid. When triturated with water, Asafetida yields a milk-white emulsion which becomes yellowish on the addition of ammonia water. Not less than 50 percent. should dissolve in alcohol. When incinerated, Asafetida should yield not more than 10 percent. of ash." *U. S.* "Asafetida should contain not less than 65 per cent. of matter soluble in alcohol (90 per cent.), and should yield not more than 10 per cent. of ash when incinerated." *Br.*

Much commercial asafetida of prime appearance, fails to come up to the requirements of the *U. S. Pharmacopœia*. Large quantities are said to be returned from the United States ports to Europe on account of their failure to contain the proper percentage of material soluble in alcohol, and in reducing the requirements from 60 to 50 per cent. the revisers of the *Pharmacopœia* have only yielded to a slight extent to the necessities of the situation. Macerated in water it produces a turbid red solution, and triturated with that fluid it gives a white or pinkish milky emulsion of considerable permanence. Touched with nitric acid (sp. gr. 1.2) the tear becomes of an evanescent green color. "If a small fragment be strongly heated in a dry test-tube, the contents of the tube, after cooling, yield with boiling water a solution which when largely diluted and made alkaline with solution of ammonia exhibits a blue fluorescence." *Br.* In 100 parts, Pelletier found 65 parts of resin, 19.44 of gum, 11.66 of bassorin, 3.60 of volatile oil, with traces of acid calcium

malate. J. Polásek examined the pure tears of *Asafetida amygdaloides*, finding the following constituents: 61.40 per cent. of resin soluble in ether, which is regarded by him to be the ferulaic acid ester of *asaresino-tannol*; 0.60 per cent. of resin insoluble in ether, regarded to be free *asaresino-tannol*; 25.10 per cent. of gum; 6.70 per cent. of volatile oil; 0.06 per cent. of vanillin; 1.28 per cent. of free *ferulaic acid*; 2.36 per cent. moisture; 2.50 per cent. impurities. *Asaresino-tannol* has the composition corresponding to the formula $C_{24}H_{35}O_5$. The author has prepared a benzoyl derivative, $C_{24}H_{33}O_5.C_6H_5CO$, and an acetyl derivative, $C_{24}H_{33}O_5.CH_3CO$, which prove it to contain a hydroxyl group,—viz., $C_{24}H_{33}O_4.OH$. Umbelliferone was obtained as a secondary product of hydrolysis with sulphuric acid from *asaresino-tannol*, and was also obtained from ferulaic acid synthetically, guaiacol being produced at the same time. By nitrification of *asaresino-tannol*, picric acid is produced. (*A. Pharm.*, 235, March, 1897, 125, 132.) The odor of the gum-resin depends on the *volatile oil*, which may be procured by distillation with water or alcohol, and amounts to from 6 to 9 per cent., according to Flüeliger. It is lighter than water, colorless when first distilled, but becomes yellow with age, of an exceedingly offensive odor, and of a taste at first flat, but afterwards bitter and acid. Hlasiwetz (*Ann. Ch. Ph.*, 71, 23) considers it a mixture, in variable proportions, of the sulphide and disulphide of a compound radical consisting of carbon and hydrogen (C_6H_{11}). Allyl persulphide, which is sublimed when oil of mustard is heated with potassium persulphide, is said by Wertheim to have an extremely intense odor of asafetida, a fact which justifies the supposition that it may be identical with the oil of that gum-resin. (Gmelin, ix. 377.) Semmler, in a later study (*Ber. d. Chem. Ges.*, 23, p. 3530, and 24, p. 78), states that it contains *pinene* and a second terpene in smaller amount, and in the higher boiling fractions, a disulphide, $C_7H_{14}S_2$; a disulphide, $C_{11}H_{20}S_2$; a body $(C_{10}H_{18}O)_n$; a disulphide, $C_8H_{16}S_2$; and $C_{10}H_{18}S_2$.

The resin is, according to Hlasiwetz and Barth (*Ann. Ch. Ph.*, 138, 61), a mixture containing *ferulaic acid*, $C_{10}H_{10}O_4$, crystallizing in iridescent needles, and obtained by precipitating the alcoholic solution with lead acetate, washing the precipitate, and decomposing it with diluted sulphuric acid. Submitted to dry distillation, the resin yields *umbelliferone*, $C_8H_8O_3$, and blue-colored oils. Fused with potassium hydroxide, ferulaic acid yields oxalic acid and carbon dioxide, several acids of the fatty series, and protocatechuic acid. The resin itself treated in like manner, after it has been freed from gum, yields resorcinol. Tschirch (*Harze und Harzebehälter*, 1900, p. 234) states that the resin is the *ferulaic ester of asaresino-tannol* containing some free *ferulaic acid*, and some *vanillin*, which latter is a product of the oxidation of the ferulaic acid.

Impurities and Adulterations.—Asafetida is often purposely adulterated; it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. Portions which are very soft, dark brown, or blackish, with few or no tears, and indisposed to assume a red color when freshly broken, should be rejected. We have been informed that a case seldom comes without more or less of this inferior asafetida, and of many it forms the larger portion. It is sold chiefly for horses. A factitious substance, made of garlic juice and white pitch with a little asafetida, has occurred in commerce. Asafetida is said to be usually mixed with wheat or barley flour or with earthy matters at the place of its production, the impurities sometimes exceeding 30 per cent. *Hingra* of the Bombay bazaars is a very stony variety, composed largely of earthy matter.

J. U. Lloyd, after examining a large number of samples of commercial asafetida, was convinced that it is impracticable to obtain the crude drug of the official standard, gypsum, carbonates, and other insoluble matters being present in large amounts. He did not find white turpentine or rosin in any of the samples; exhausting asafetida with alcohol and evaporating the alcohol carefully, he obtained an extract for which he proposed the name of *Purified Asafetida*. (*Ph. Rev.*, 1896.) H. William Jones (*Y. B. P.*, 1900, 503) purifies asafetida by pouring a concentrated alcoholic solution into water slightly acidulated with hydrochloric acid, collecting the precipitate, washing and drying it.

Asafetida is sometimes kept in a powdered state, but this is objectionable, as the drug is thus necessarily weakened by the loss of volatile oil, and is more liable to adulteration.

Uses.—Asafetida acts primarily as a stimulant antispasmodic, and as an efficient expectorant and feeble laxative. Some consider it also emmenagogue and anthelmintic. Its volatile oil is undoubtedly absorbed, as its peculiar odor may be detected in the breath and the secretions. As an antispasmodic, it is employed in the treatment of *hysteria*, *hypochondriasis*, *convulsions* of various kinds, *spasm of the stomach and bowels* unconnected with inflammation, and in numerous other nervous disorders of a merely functional character. From the union of expectorant with antispasmodic powers, it is highly useful in *spasmodic pectoral affections*, such as *whooping cough* and *asthma*, and in certain *infantile coughs* and *catarrhs*, complicated with nervous disorder, or with a disposition of the system to sink. In *catarrhus senilis*; in the secondary stages of *peripneumonia notha*, *croup*, *measles*, and *catarrh*; in *pulmonary consumption*; in fact, in all cases of *subacute or chronic disease of the chest* in which there is want of due nervous energy, asafetida may be occasionally prescribed with advantage. In the form of enema, it is useful in cases of *inordinate accumulation of air in the bowels*, and also in the *hysteric paroxysm* and

other functional convulsions. Its laxative tendency is often advantageous, and it may be usefully combined with cathartics in *flatulent constipation*.

It appears to have been known in the East from very early ages, and, notwithstanding its repulsive odor, is at present much used in India and Persia as a condiment. Persons soon habituate themselves to its odor, which they even learn to associate pleasantly with the agreeable effects experienced from its internal use. Children with whooping cough sometimes become fond of it.

Asafetida may be given in pill or emulsion. The tincture is official, and is much used. When given by injection, the gum-resin should be triturated with warm water. From half a drachm to two drachms (2 to 7.7 Gm.) may be administered at once in this way. It may also sometimes be conveniently used in the form of a suppository, or plaster. (See *Emplastrum Asafetide*, 18th ed. U. S. D., p. 238.) A syrup has been recommended in which the fetid odor of the drug is disguised by the use of the infusion of wild cherry bark.¹ (See *A. J. P.*, 1871, p. 397.)

Dose, of asafetida, five to ten grains (0.32 to 0.65 Gm.).

ASPIDIUM [Male Fern]

(as-pid'i-um)

"The dried rhizome of *Dryopteris Filix-mas* (Linné) Schott, or of *Dryopteris marginalis* (Linné) Asa Gray (Fam. *Filices*)."
"The rhizome of *Aspidium Filix-mas*, Swartz. Collected late in the autumn, divested of its roots, leaves, and dead portions, and carefully dried. Male Fern should not be kept more than a year." *Br.*

Filix Mas, *Br.*, and *U. S.* 1870; *Stipites aspidii*, *Radix Filicis maris*, Male Shield Fern, Knotty or Sweet Brake, Basket Fern, Bear's-paw Root; *Fougère Mâle*, *Fr.*; *Rhizoma Filicis*, *P. G.*; *Wurmfarnwurz*, *Waldfarne*, *Johanniswurz*, *Farnwurz*, *G.*; *Felce maschio*, *It.*; *Helecho macho* (*Rhizoma de*), *Sp.*

As the term *Dryopteris* was first used by Amman in 1739, and applied in 1763 by Adanson, as the name of the genus to which the *Aspidium* was applied in 1800 by Swartz, the use of the generic term *Dryopteris* would seem to be necessitated by the ordinary laws of

botanic nomenclature. The synonyms of the male fern are extraordinarily numerous. We append some of them: *Aspidium Filix-mas*, of many authors; *Polypodium Filix-mas*, Linn.; *Polystichum Filix-mas*, Roth.; *Nephrodium Filix-mas*, Rich.; *Lastrea Filix-mas*, Presl.; *Tectarea Filix-mas*, Cavan.; *Dryopteris Filix-mas* (L.), Schott; *Lophodium Filix-mas*, Newm.; *Polypodium nemorale*, Salisb.; *Polystichum durum et induratum*, Schur.; *Polystichum abbreviatum*, De Candolle; *Aspidium mildeanum*, Göppert; *Dryopteris affinis*; *Polypodium heleopteris*. Under the name of *inkomankomo* or *uncomocomo*, the rhizome of *Aspidium athamanticum* (Hook.), Kuntze, has long been used by the South African Kaffirs, and has entered European commerce as *pannum*. The male fern has a perennial, horizontal root or rhizome, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe, or footstalk, and midrib are thickly beset with brown, tough, transparent scales; the frond itself is oval-lanceolate, acute, pinnate, and of a bright green color. The pinnæ or leaflets are remote below, approach more nearly as they ascend, and run together at the summit of the frond. They are deeply divided into lobes, which are of an oval shape, crenate at the edges, and gradually diminish from the base of the pinna to the apex. The fructification is in small dots on the back of each lobe, placed in two rows near the base, and distant from the edges. The plant is a native of Europe, Asia, and the north of Africa. It is also found in some of the Polynesian islands, and grows in British America, following the Rocky Mountain chain through Mexico, Venezuela, etc., as far south as Peru.

In the Eastern United States it is replaced by *D. marginalis* and *D. Goldieana* (Hook.), A. Gray. *D. marginalis* has an ovate oblong frond, one or two feet long, with lanceolate pinnæ, with broad almost sessile bases and oblong obtuse crowded pinnules. It differs from *D. Filix-mas* by having its fruit dots upon the margin of its evergreen fronds.

It is probable that most species of the genus, if not of the family, are medicinally active. J. L. Patterson (*A. J. P.*, 1875) found that the *D. marginale* contained all of the active principles of *D. Filix-mas*, and Chas. H. Cressler has demonstrated the activity of its oleoresin. (*Ibid.*, 1878.) According to V. Penndorf (*Ap. Ztg.*, 1903), in Germany the rhizomes of *D. spinulosum* and *Athyrium Filix-femina* are frequently found mixed with those of the true male fern, in quantities varying from five to ninety per cent. The rhizomes of *D. Filix-femina* are readily recognized by having only two large dumb-bell shaped steles. The rhizomes of *D. spinulosum* closely resemble those of the genuine drug, but it is stated that they can be distinguished by the numerous small glands found on the margin of their scales, the scales of *D. Filix-mas* having only two upon each. On account of this substitution, many

¹ J. W. Wood prepares syrup of asafetida by dissolving 256 grains of asafetida in two fluidounces of glycerin by the aid of a gentle heat, and straining. He then dissolves 15 drops oil of wintergreen, 5 drops oil of cinnamon, and 1 drop oil of bitter almond, in three fluidrachms of 95 per cent. alcohol, and adds to it the above, together with enough simple syrup to make one pint. Each fluidrachm represents two grains of asafetida. (*A. J. P.*, 1874.)

of the German extracts of the male fern are said to contain *aspidin*, a yellow crystalline substance having a melting point of 124° to 125° C., which is found only in *D. spinulosum*. (*Ap. Ztg.*, 1903.) Lauren of Helsingfors states that the extract of *A. spinulosum* is a very active tannicide, and is less apt to produce disagreeable sensations in the patient than is the official drug. He gives the dose as 60 grains (3.9 Gm.), followed by a laxative, and states that some Finnish apothecaries are especially noted for their fern extracts, because they use only the rhizome of *A. spinulosum*. (*Ap. Ztg.*, 1903.) On the Pacific slope the indigenous *A. rigida*, Underw., is locally used against the tapeworm, and W. J. Bowman has found in it filicic acid and resin. Popular belief has long ascribed tænicidal virtues to our native *Asplenium Filix-femina*. It occurs in conical pieces from 8 to 13 centimeters long, 2 to 5 centimeters in diameter, of a reddish-brown color, covered with root fibres and leaf scars. According to R. Kürsten (*P. J.*, xxii, 1891), its active principle is closely allied to filicic acid, differing in being especially soluble in strong alcohol, in subliming at 80° C., and in not yielding isobutyric acid when heated in a sealed tube with water. *Pannic acid* crystallizes in thin, shining, light yellow, rectangular prisms, melting at 187° C. (368.6° F.).

Heffter (*A. E. P. P.*, 1897, 458) finds three well characterized and crystallized principles in pannum: *flavopannin*, $\text{C}_{21}\text{H}_{28}\text{O}_7$, crystallizing in citron-yellow prisms, melting at 151° C., and soluble in ether, benzene, acetic ether, acetone, and boiling methyl and ethyl alcohols, insoluble in petroleum ether and water; *albo pannin*, $\text{C}_{21}\text{H}_{28}\text{O}_7$, crystallizing in silky-white needles, which melt at 147° C.; and *pannol* (pannic acid of Kürsten), $\text{C}_{21}\text{H}_{24}\text{O}_8$, fusing at 192° C., which is easily soluble in hot glacial acetic acid and acetone, more difficultly soluble in alcohol and ether, and very slightly soluble in petroleum benzin, benzene, and water. The alcoholic solution is colored intensely dark green with ferrie chloride. Heffter compares these three compounds with the three obtained from *D. Filix-mas*, and finds a close chemical and therapeutic correspondence between *aspidin* and *flavopannin*, between *albaspidin* and *albo pannin*, and between *aspidinol* and *pannol*. According to the experiments of A. Heffter, both *flavopannin* and *albo pannin* are powerful muscle poisons, directly affecting the heart. (*A. E. P. P.*, Bd. xxxviii.)

According to Peschier of Geneva, *Aspidium* deteriorates rapidly when kept, and in about two years becomes entirely inert. The rhizomes of other species of fern are frequently substituted for the official, and in the dried state it is difficult to distinguish them. The varying results reported by physicians when using this drug, can undoubtedly be ascribed to the employment of spurious male fern, or old brownish rhizomes which should have been thrown away.

Properties.—As taken from the ground, the rhizome consists of a long cylindrical cau-

dex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are an inch or two in length, from two to four lines thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the rhizome with thin silky scales of a light brown color. From between these remains of the footstalks emerge numerous small radical fibres. The whole rhizome, thus constituted, presents a somewhat flexible, cylindrical mass, one or two inches thick, and from three inches to a foot or more in length. In this form, however, it is not usually found in commerce. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the rhizome attached to their base, where they are surrounded by the silky scales. These fragments, as seen in commerce, often appear as if long kept, and are probably, in general, much deteriorated by time. The official description is as follows: "Before being peeled, 10 to 15 Cm. long by 5 to 7 Cm. thick, including the densely imbricated, dark brown, cylindrical, slightly curved stipe-bases and the dense mass of brownish, glossy, transparent, soft, chaffy scales; when peeled, 1 to 2 or 3 Cm. thick, cylindrical and nearly straight, or curved and tapering towards one end, roughly scarred with remains of the stipe-bases, or bearing several coarse longitudinal ridges and grooves; pale green when first peeled, becoming pale brown; fracture sharp, pale green, the texture rather spongy, exhibiting from 6 to 10 steles in a loose and interrupted circle; odor disagreeable; taste bitter-sweet, astringent, acid, and nauseous. The chaff, together with the dead portions of the rhizome and stipes, should be removed, and only such portions used as have retained their internal green color. Powdered *Aspidium* should be freshly prepared and have a bright green color." *U. S.* In collecting male fern, all the black discolored portions should be cut away, the fibres and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then pulverized; and the powder should be kept in small well-stoppered glass bottles.

Microscopic examination shows that it is composed of polyhedral, porous-walled cells and vascular bundles containing scalariform ducts; in *D. Filix-mas* ten of these bundles are larger than the others, and are arranged in an attempted circle near to the surface; while in *D. marginale* there are only six bundles in the circle. It has been analyzed by H. Boek, who gives as its constituents volatile oil, fixed oil, resin, starch, vegetable jelly, albumen, gum, sugar, tannic and gallic acids, pectin, lignin, and various salts. (*See A. J. P.*, xxiv 64.) Peschier ascertained that the active properties reside in the ethereal extract, which is the fixed oil is an impure mass, containing

volatile oil, resin, coloring matter, etc. It is a thick dark liquid, with the odor of the fern, and a nauseous, bitterish, somewhat acid taste. E. Luck found in it a peculiar acid, which he denominated *filicic acid*. Dacomo gives to filicic acid the formula $C_{14}H_{18}O_5$, and finds in addition a white waxy substance, melting at $80^\circ C.$, with the formula $(C_{13}H_{25}O)_n$, glucose, tannin, a red coloring matter (*filix red*), a green oil which he separated into several fractions, and two resins, one brick-red, melting at 85° to $93^\circ C.$, the other black and plastic. He considers that filicic acid is probably an isobutyric acid derivative of hydroxynaphthaquinone. Poulson (*A. E. P. P.*, 1891) states that, when pure, crystalline, inactive filicic acid is dissolved in alkalies and reprecipitated by an acid, the amorphous precipitate possesses the active properties of the extract. He thinks that the inactive crystalline body is an anhydride or lactone of the amorphous filicic acid, and should be called *filicin*. Böhm announced three additional substances which he named *flavaspidic acid*, *albaspidin* and *aspidinol*. Kraft (*Ph. Ztg.*, 1903, p. 275) confirms this and finds in addition, *flavaspidin*, and an amorphous acid which he names *filmaron*, which pharmacological examination has proven conclusively to be the true anthelmintic constituent of male fern. *Filmaron* is a bright yellowish-brown powder, insoluble in water, difficultly soluble in cold alcohol, but very soluble in other general solvents. The rhizome contains about 5 per cent. of *filmaron*. Its formula is $C_{47}H_{54}O_{16}$. The other different constituents seem to be largely decomposition products of *filmaron*. For an assay method for male fern extract, see *Am. Drug.*, 1897, 73.

Uses.—Male fern was used by the ancients, and is mentioned as a vermifuge in the works of Dioscorides, Theophrastus, Galen, and Pliny, and by some of the earlier modern writers. But it does not appear to have been generally known till about the year 1775, when the King of France purchased from Madame Nouffer, the widow of a Swiss surgeon, a secret remedy for *tape worm*, which proved to be the powdered root of the male fern. The oleoresin of male fern is a very efficient tænicide, and is also much used against the *anchylostoma*. According to the experiments of W. Straub (*A. E. P. P.*, xlviii, 1902), the active principles of male fern are violent muscular poisons, and probably kill the *tape worm* by acting directly upon their muscle cells. It is, however, in overdose a distinct poison, Katayama and Okamoto (*Sei-ikwai*, July, 1892) having collected from literature twenty-two cases of poisoning by it, of which five proved fatal. Six drachms have caused death. (*L. L.*, 1882.) The symptoms have been vomiting, diarrhoea, vertigo, headache, tremor, cold sweat, dyspnoea, cyanosis, mania, coma, convulsions. In nearly half of the cases there was amblyopia, or even amaurosis, with dilated, fixed pupils; the loss of sight is usually temporary, but has proved permanent. Kata-

yama and Okamoto succeeded in producing blindness in the lower animals. They believe that the use of castor oil with the male fern notably increases the absorption of the extract. Prevost and Binet have found that in the lower animals, given hypodermically, the oleoresin produces violent dyspnoea and death from arrest of the heart in systole, and Fröhner has found parenchymatous nephritis in animals fatally poisoned by it. For the expulsion of *tape worm*, the patient should live upon milk and a little bread for one day, and the following morning take a full dose, one-half to one fluidrachm (1.8 to 3.75 Cc.) of the oleoresin, fasting, and repeating it in two or three hours. At noon the patient may resume the use of food, and in the evening a brisk cathartic should be given. Male fern is said (with doubtful accuracy) to prove more effectual against the *tape worm* of the Swiss (*Bothriocephalus latus*) than against *Tænia solium*, which is more frequent in France and England. (Bremsler.)

Dose, one to two drachms (3.9 to 7.7 Gm.).

Off. Prep.—Oleoresina Aspidii, U. S. (Br.).

ATROPINA. U. S., Br.

ATROPINE

(ät-rō-pī'nä)

$C_{17}H_{23}NO_3 = 287.04$

"An alkaloid obtained from *Atropa Belladonna* Linné (Fam. *Solanaceæ*) and from other plants of the same family. As it occurs in commerce, it is usually accompanied by a small amount of hyoscyamine, from which it cannot be readily separated. It should be kept in amber-colored, well-stoppered vials." U. S. "An alkaloid, $C_{17}H_{23}NO_3$, obtained from *Belladonna Leaves* or *Root*." Br.

Atropia; Atropine, Fr. Cod.; Atropinum, P. G.; Atropin, G.; Atropina, It., Sp.

Because atropine cannot profitably be manufactured on a small scale, both Pharmacopœias have omitted the processes of preparation, and furnish only qualitative tests. For the U. S. process of 1870, see U. S. D., 14th edition.

Properties and Tests.—Atropine is in "white rhombic prisms, more or less elongated in the direction of the major axis as they contain more or less hyoscyamine; odorless; possessing a bitter, acid taste (*it should be tasted with the utmost caution and only in dilute solution*). Atropine shows an alkaline reaction with litmus, phenolphthalein, and hematoxylin T.S. Pure atropine chloraurate melts at $136^\circ C.$ ($276.8^\circ F.$). Pure hyoscyamine chloraurate melts at $160^\circ C.$ ($320^\circ F.$). Pure hyoscyne chloraurate melts at $197^\circ C.$ ($386.6^\circ F.$). Atropine chloraurate alone melts under boiling water. At about $113.8^\circ C.$ ($237^\circ F.$) Atropine melts, forming a colorless liquid; the melting point of Atropine free from hyoscyamine is about $115.8^\circ C.$ ($240.4^\circ F.$). When ignited, it is consumed without leaving a residue.

Soluble in 450 parts of water, 1.46 parts of alcohol, 16.6 parts of ether, and 1.56 parts of chloroform at 25° C. (77° F.); soluble in 86.7 parts of water at 80° C. (176° F.); and in 0.9 part of alcohol at 60° C. (140° F.). On adding sulphuric acid to Atropine, no color should be produced (absence of readily carbonizable organic impurities), nor should any color be developed upon the subsequent addition of nitric acid (absence of, and difference from, morphine). In a solution of Atropine in hydrochloric acid, platonic chloride T.S. produces no precipitate (difference from most other alkaloids). Gold chloride T.S. yields a yellow, lustreless precipitate in such a solution. If a few crystals of Atropine be placed in a porcelain dish on a water-bath with a few drops of nitric acid, and heated to dryness, a yellow residue will be produced; if on cooling a few drops of alcoholic potassium hydroxide T.S. and a fragment of potassium hydroxide be added, an intense violet color is produced; hyoscyamine and hyoscyne will produce the same color, but the presence of strychnine masks the reaction. If a crystal of Atropine be added to a few drops of sulphuric acid containing 1 drop of creosol, a pink color should be produced, which is not dissipated by the addition of 0.5 Gm. of hydrated chloral (distinction from other alkaloids, hyoscyamine producing a brown color and strychnine a black, hyoscyne remaining colorless). If a small quantity of Atropine, or one of its salts, be heated with a few Cc. of sulphuric acid, a peculiar odor, recalling that of a mixture of rose, orange flower, and melilot, will become noticeable. The addition of a few fragments of potassium dichromate will change this odor to that of bitter almond." *U. S.* The British Pharmacopœia states that atropine is "soluble in 300 parts of water, readily soluble in alcohol (90 per cent.), in chloroform, and in ether. . . . Melting point 239° to 240° F. (115° to 115.5° C.). . . . When moistened with fuming nitric acid and evaporated to dryness on a water-bath, the residue gives with freshly prepared alcoholic solution of potassium hydroxide a fugitive reddish-violet coloration. It leaves no ash when burned with free access of air (absence of mineral matter)." *Br.* For further information, see *Belladonna*; also *A. J. P.*, 1884, 206.

It is inflammable, giving off an odor like that of benzoic acid, and, when burned in the open air, leaves no residue. By distilling it with potassium dichromate and sulphuric acid, E. Pfeiffer succeeded in obtaining crystals of benzoic acid and propylamine. (*A. J. P.*, 1864, 226.) Kraut, by heating it with baryta water, succeeded in obtaining a peculiar acid and peculiar base, the former of which he calls *tropic acid*, $C_8H_{10}O_3$, melting at 117° C., and oxidizable by diluted potassium permanganate to bitter almond oil and benzoic acid, and the latter *tropine*,¹ $C_8H_{11}NO$, melting at 62° C.

(*Ibid.*, 232.) Ladenburg (*Ber. d. Chem. Ges.*, 12, 942, and 13, 104) has succeeded in effecting the synthesis of atropine from these two constituents, which, when heated over a water bath in the presence of diluted hydrochloric acid, unite to form the alkaloid; later (*Ph. Ztg.*, 1902, 355), he produced tropine by the direct action of hydrobromic acid on tropidine. Willstätter produced tropidine synthetically and the following synthetic chain was completed: Glycerin, glutaric acid, suberone, tropidine, tropine, tropic acid, and atropine. Ladenburg also succeeded in forming a series of compound esters of tropine with other organic acids to which the general name of *tropine*s has been given. Some of these have pronounced toxic effects, and one (homatropine) has found use as a valuable substitute for atropine. The list of artificial tropinees thus prepared includes:

Benzoyl-tropine, $C_{15}H_{19}NO_2 + 2H_2O$, not mydriatic; *salicyl-tropine*, $C_{15}H_{19}NO_3$, strong base, weak poisonous action; *m-oxybenzoyl-tropine*, $C_{15}H_{19}NO_3$; *p-oxybenzoyl-tropine*, $C_{15}H_{19}NO_3 + 2H_2O$; *phenylacet-tropine*, $C_{16}H_{21}NO_2 + H_2O$; *oxytoluyl-tropine* (homatropine), $C_{16}H_{21}NO_3$, has mydriatic action, and is less poisonous than atropine; *cinnamyl-tropine*, $C_{17}H_{23}NO_2$, strong base, but without mydriatic action; *atropyl-tropine*, $C_{17}H_{23}NO_2$; *atrolactyl-tropine*, $C_{17}H_{23}NO_3$, has similar action to atropine; *phthalyl-tropine*, $C_{21}H_{25}NO_4$; *lactyl-tropine*, $C_{18}H_{23}NO_3$.

Hinterberger states that an alcoholic solution of atropine, when cyanogen is passed through it, assumes a blood-red color, and, on spontaneous evaporation, deposits a red, syrupy liquid insoluble in water. (Gmelin.) The detection of atropine in small quantity is a matter of great difficulty; the best test is the physiological, which consists in placing the suspected liquid in the eye of a cat, or other animal, when, if the alkaloid be present, dilatation of the pupil will occur. According to Brunner, the best chemical test is the aromatic odor which is produced by adding the alkaloid and a little water to a hot mixture of sulphuric acid and potassium dichromate or ammonium molybdate. (*P. J.*, iv. 385.) Fabris believes that strychnine in the presence of atropine interferes with the toxicological identification of the latter by chemical tests, but a physiological test

rise to vasomotor constriction by exciting the vasomotor constrictors, and that it sometimes causes vasomotor dilatation by exciting vasomotor dilator nervous elements. As the result of an elaborate series of experiments, Gottlieb (*A. E. P. P.*, Bd. xxxii., 1896) has reached the conclusions: First, that some of the tropinees not only differ quantitatively in their action from atropine, but are wanting in the peripheral action of that alkaloid: such are *acetyl-tropine* and *succinyl-tropine*. Second, as far as our knowledge goes, there seems to be a complete parallelism in the action of the tropinees and the tropinees on the ends of the vagi in the heart and the pupils. (This influence can be seen in certain fatty acid esters, and may be wanting in some aromatic tropinees.) Third, the tropinees and the less poisonous tropinees are cardiac stimulants, an influence not shared by atropine. [This latter assertion is probably incorrect.] The influence upon the heart probably consists in an increasing of the excitability of the motor heart ganglia.

¹ The physiological action of tropine hydrochloride has been partially investigated by H. G. Beyer. (*Med. News*, Aug. 27, 1887.) He concludes that it gives

reveals the presence of both alkaloids. (*B. S. Ph. Br.*, 1894.) Wormley made comparative examinations of various tests for atropine, hyoscyamine, and hyoscyne. (*A. J. P.*, 1894, 513.)

Uses.—The local and general effects of atropine on the system are precisely those of belladonna. It is, however, more speedy in its operation, probably in consequence of its easier absorption. Thus, the poisonous action of belladonna is seldom experienced in less than half an hour, while that of atropine shows itself violently in fifteen or twenty minutes. The most prominent effects from small remedial doses are dryness and stricture of the throat, and slight uneasiness of the head, with confusion or giddiness; from somewhat larger doses, dilatation of the pupil, some dimness of vision, frontal headache, hurried respiration, slight delirium, flushed face, and sometimes a scarlet rash. After poisonous doses the above symptoms occur in a more aggravated form. Two distinct stages of the poisoning can usually be noted. At first there is great dimness or total temporary loss of vision, excessive dilatation of the pupil, headache, delirium, which is always talkative and may be violent, an enormous increase in the frequency of the pulse, which is also small and hard, an elevation of the bodily temperature, and decided increase of the rate of respiration. Subsequently the second stage develops, and paralytic symptoms set in; the delirium gives way to stupor, restlessness to paralytic weakness, the pulse becomes very feeble, the surface cold, the respirations grow more and more shallow, and death from failure of both respiration and circulation occurs.

In some instances violent convulsions have occurred; nausea and vomiting, and even diarrhoea, are occasionally produced. In a case recorded by J. Andrew two-thirds of a grain of atropine occasioned the most alarming symptoms, which continued for several days (*Ed. M. J.*, xiv. 34); and a lady under the care of Roux of Brignolles, took somewhat more than a grain, with the same alarming symptoms (*Ann. Thér.*, 1861, p. 14), though in both cases recovery took place under treatment. In a child three years old less than half a grain was followed by similar dangerous symptoms and the same favorable result. (*M. T. G.*, Dec. 1850, p. 601.)

The external use of atropine is not without danger, unless great caution be observed. A case is on record in which an ointment composed of three grains of the sulphate and two drachms of lard, applied upon a vesicated surface on the neck, produced in a few minutes the most violent symptoms of belladonna poisoning, ending in death in two hours. (*Ann. Thér.*, 1867, p. 9.) The alkaloid will produce its characteristic constitutional effects when applied to the skin denuded of the epidermis, or to a mucous membrane, as of the rectum, vagina, etc., and especially when injected into the subcutaneous areolar tissue.

The treatment for atropine poisoning is the same as that for belladonna, the most prominent measures being evacuation of the stomach, cold applications to the head, the preparations of opium internally, and stimulants when the strength is failing. As the value of atropine in opium poisoning, which seems unquestionable, is due to its influence on the respiratory centres, it is far from certain that opium is of any proportionate advantage in poisoning by belladonna, etc. Pilocarpine and physostigmine are also physiological antagonists to atropine and may be rationally used. The official compound solution of iodine has been given as a chemical antidote to atropine, and with asserted advantage. It acts by forming an insoluble compound with the alkaloid. (See *Belladonna*.)

Atropine is eliminated by the kidneys, and may produce increased diuresis but usually there is, in cases of poisoning, retention of urine from vesical paralysis. The increase of the heart's action by atropine is chiefly due to its paralyzing the peripheral vagi, the inhibitory nerves of the heart; the final cardiac failure which takes place when poisonous doses have been taken is apparently the result of a direct depressant action on the heart muscle. Upon the vasomotor centres atropine in a moderate dose acts as a stimulant, thereby causing a great rise of the arterial pressure. After poisonous doses the primary vasomotor spasm is followed by dilatation of the vessels and great fall of the arterial pressure. Paralysis of the motor nerves is one of the most marked effects of the poison; upon the afferent nerves the poison seems to have but little influence. On all non-striated muscle atropine exerts a very powerful influence, and it is probable, although not certain, that while in poisonous amount it lessens and finally paralyzes intestinal movements by a direct action upon the muscular coats, in small doses it increases peristalsis by paralyzing the inhibitory nerves which control this intestinal function. The action of the drug upon the respiratory centres is a very important one, atropine being in moderate doses one of the most powerful and persistent stimulants to the respiratory centres known. The asphyxia of belladonna poisoning is certainly in large measure due to the paralysis of the nerve-trunks which the poison produces, although it is also probable that the first period of excitation of the respiratory centres is followed by one of depression.

Atropine chiefly depends for its therapeutic powers upon—1st, its sedative action upon the peripheral nerves; 2d, its stimulant action on the respiratory centres; 3d, its influence upon the heart and vasomotor centres; 4th, its effects upon glandular structures. By virtue of its first-mentioned power it is useful in *spasmodic diseases*, such as *whooping cough*, *dysmenorrhœa*, *local spasm*, etc. As the action is upon the nerve trunks, the remedy is much more effective when it can be applied locally, as by

atomization in *whooping cough* and *asthma*, or by hypodermic injection in *wry neck*. As atropine has some influence upon the afferent nerves, it has some power of relieving *pain*; but for this action to be marked, direct application is necessary. On account of its influence upon respiration, it is invaluable in *narcotic poisonings* and other bodily conditions with failure of this function. In *shock* and other similar states in which vasomotor paralysis is an important part of the morbid condition, it is a very useful stimulant. On account of the paralyzing influence which it has upon the inhibitory intestinal nerves, atropine may be used as an adjuvant to more decided laxatives.

On the glandular system atropine exerts a decided influence, its effect upon the salivary and perspiratory glands being at present best understood. The remarkable action which it has in checking the functional activity of these glands is probably exerted through the nervous system, for in Keuchel's experiments it was distinctly proved that the chorda tympani nerve, excitation of which normally provokes salivation, is paralyzed in atropine poisoning. In *ptyalism* and in *colliquative sweats* the most prompt effects can be obtained from the hypodermic use of atropine. The hypodermic dose of atropine may be set down as the one-hundredth of a grain (0.0006 Gm.), the dose by the mouth as the one-seventy-fifth of a grain (0.0008 Gm.), although in serious cases these amounts may be much exceeded. Thus in *ileus* German clinicians have given as high as the one-twentieth of a grain (0.003 Gm.) as a dose. On the other hand in susceptible persons, one-hundredth of a grain (0.0006 Gm.) will produce decided dryness of the throat, and one-fiftieth of a grain (0.0013 Gm.) is alleged to have caused toxic symptoms. As atropine itself is nearly insoluble, the sulphate should always be preferred. For application to the sound skin, the form of ointment or oleate is most convenient. The ointment may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. The oleate is now official. Glycerin has been recommended as a vehicle for atropine for external use, and may be incorporated with it in the same proportion.

A solution of atropine upon being dropped into the eye produces dilatation of the pupil after ten or fifteen minutes, without causing congestion or inflammation; and the dilatation will usually continue for three or four days. It is said that the dilatation is sometimes followed by contraction of the pupil, especially when the dose is large. When solution of atropine sulphate is used for *dilating the pupil*, it may be either dropped into the eye within the lower lid, or introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular disks of gelatin, made by mixing the solution with gelatin and evaporating so as to produce a thin film, which is to be cut into circular pieces. (See *Lamellæ Atropinæ*.) These

have the advantage over paper that they do not require to be subsequently removed from the eye.

Atropine may be administered internally for all the purposes for which belladonna is given; and it is very largely used as a local remedy, for application to the eye, or to the surface of the body, or for subcutaneous injection; and for these purposes it has the advantage over the ordinary preparations of belladonna of greater precision of dose, quickness of action, and neatness and cleanliness.

The solution of atropine or its salts¹ is very prone to have developed in it a fungous growth with consequent decomposition of the alkaloid.

Dose, of atropine, one two-hundredth to one one-hundredth of a grain (0.0003 to 0.0006 Gm.).

ATROPINÆ SULPHAS. *U. S.*, *Br.*

ATROPINE SULPHATE

(āt-rō-pī'næ sŭl'phās)

$(C_{17}H_{23}NO_3)_2 \cdot H_2SO_4 = 671.43$

"The sulphate $[SO_2(OH)_2 \cdot (C_{17}H_{23}NO_3)_2]$ of an alkaloid obtained from *Atropa Belladonna* Linné (Fam. *Solanaceæ*), and from other plants of the same family. As it occurs in commerce, it usually contains a small amount of hyoscyamine sulphate, from which it cannot be readily separated." *U. S.* "Atropine Sulphate, $(C_{17}H_{23}NO_3)_2 \cdot H_2SO_4$, may be obtained by neutralizing Atropine with Diluted Sulphuric Acid." *Br.*

Sulphate of Atropia; Sulfate d'Atropine, *Fr. Cod.*; Atropinum Sulfuricum, *P. G.*; Schwefelsaures Atropin, Atropinsulfat, *G.*; Solfato di atropina, *It.*; Sulfato de atropina, *Sp.*

Neither the *U. S.* nor *Br.* Pharmacopœias give a process for preparing this salt. The official formula of 1870 is essentially the process of Ch. Maitre, which is as follows: "Take of Atropia, *sixty grains*; Stronger Ether, *four fluidounces* and a half; Sulphuric Acid, *six*

¹ *Atropine Salicylate*.—This salt is alleged to have advantages over the sulphate, mainly because of its more rapid and efficient action, provided it be pure and perfectly neutral. It may be prepared by Frederick's process, which is to dissolve 23 parts of atropine in pure alcohol by a gentle heat, and to add enough salicylic acid (about 18 parts) to render the solution neutral, which is determined by the use of litmus paper. The solution is carefully evaporated, and finally dried in a drying oven. It is deliquescent, and should be kept in securely stoppered vials. The dose is the same as that of the sulphate.

Atropinum Santonicum, a compound of atropine and santonic acid, is described by Bombelon (*Ph. Ztg.*, April, 1886) as an amorphous non-hygroscopic powder, readily soluble in water, which presents advantages over all other atropine salts in being non-irritating, and also in affording a solution which is stable if kept in yellow glass bottles to avoid the formation of photo-santonin acid. One drop of a solution of 0.01 Gm. in 20 Gm. of water is sufficient to dilate the pupil, the dilatation disappearing in from twelve to twenty-four hours. The powder should be kept in amber-colored vials to protect it from the light.

grains; Stronger Alcohol, a *fluidrachm.* Dissolve the Atropia in the Ether; then mix the Acid and Alcohol, and add the mixture, drop by drop, to the ethereal solution until the Atropia is saturated. Allow the liquid to stand until the precipitate formed is deposited. Then decant the ether, and expose the residue to spontaneous evaporation until the salt is dry." *U. S.* 1870. Atropine being soluble in ether, while its sulphate is insoluble in that fluid, a convenient method is afforded for preparing the sulphate with little evaporation. By adding the mixed acid and alcohol to the ethereal solution, the sulphate is formed, and, being insoluble in the ether, is deposited, while the little left dissolved in the alcohol is obtained by spontaneous evaporation. The quantity of acid added is intended to be just sufficient to saturate the alkaloid; but if the saturation should not be exact, it would be easy to render it so by the addition of a little more alkaloid or a little more acid, as required.

From the great facility with which atropine undergoes change, much caution is necessary in preparing its salts, and the process was arranged in reference to this caution. Upon the addition of the mixed acid and alcohol to the ethereal solution, the liquid becomes milky, and deposits on the sides of the vessel a copious precipitate of a viscid appearance, which soon dries upon the decantation of the ether and the placing of the vessel in a drying-room. To succeed with this process it is necessary that the liquids employed should be carefully freed from water, the sulphuric acid being monohydrated, and that the temperature should be kept as low as possible. There should be no excess of acid; and, if such an excess should be found upon applying the test of litmus paper, the solution should be neutralized by a portion of reserved solution of atropine. (*A. J. P.*, xxviii. 361; from *Répert. de Pharm.*)

Properties.—"A white crystalline powder or microscopical needles and prisms (the form of the latter being probably due to the hyoscyamine present); odorless, having a very bitter, nauseating taste, and permanent in the air. It should be tasted with the utmost caution, and only in dilute solution. Soluble in 0.38 part of water, 3.7 parts of alcohol, 2140 parts of ether, and in 620 parts of chloroform at 25° C. (77° F.); soluble in 0.22 part of water at 80° C. (176° F.), and in 1.9 parts of alcohol at 60° C. (140° F.). At about 189.9° C. (373.8° F.) Atropine Sulphate melts; when free from hyoscyamine it melts at about 188° C. (370.4° F.). When ignited it chars, emits acrid vapors, and is rapidly and completely consumed. On adding potassium hydroxide T.S. to a solution of Atropine Sulphate, a white precipitate of atropine is obtained, which should respond to the reactions and tests given under *Atropina*." *U. S.* "Soluble in 10 parts of alcohol (90 per cent.) and in 1 part of cold water, forming solutions which are neutral to litmus, and which, even when considerably diluted, if

applied to the eye will dilate the pupil. It is insoluble in ether and in chloroform. It yields the characteristic reactions with the tests for sulphates. Melting point 361.4° F. (183° C.)." *Br.*

If it be required to procure the sulphate in the form of crystals, which may sometimes be desirable to avoid adulteration, the process of Laneau may be employed. A solution of crystallized atropine in absolute alcohol, in the proportion of 2.89 parts of the former to 4 parts of the latter by weight, having been made with the assistance of a gentle heat, 0.4 part of sulphuric acid of the sp. gr. 1.85, diluted with 3 parts of absolute alcohol, is to be gradually added, and stirred with a glass rod, until saturation, as shown by test paper, is effected. The solution is then allowed to evaporate spontaneously, and the thinner the stratum the sooner will the process be completed. The crystals are in colorless needles more or less interlaced. (See *A. J. P.*, 1863, p. 315.)

Uses.—The effects of the salt on the system are precisely the same as those of atropine, and it may be used in the same dose. Its great advantage over the alkaloid is its solubility in water. A one per cent. solution is said to be instantaneously efficacious in *toothache*, applied to the denuded dental pulp, and also to produce complete insensibility of the dental nerves, in cases in which an artificial tooth is inserted in a living root. (*Ann. Thér.*, 1861, p. 19.)

Dose, one two-hundredth to one one-hundredth of a grain (0.0003 to 0.0006 Gm.).

SWEET ORANGE PEEL

(au-răn'ti-i dŭl'cis cŏrtĕx)

"The recently separated outer rind of the ripe fruit of *Citrus Aurantium* Linné (Fam. Rutaceæ)." U. S.

Cortex Aurantiorum Dulcium; Ecorce (Zestes) d'Oranges douces, Fr.; Apfelsinenschalen, G.; Scorze del frutto dell' arancio, It.; Corteza de naraja dulce, Sp.

The U. S. Pharmacopœia includes two kinds of orange peel, bitter and sweet, the former obtained from *Citrus vulgaris*, Risso (*C. amara* (L.), Lyons, *C. Bigaradia*, Loisel.); the latter from *Citrus Aurantium*, L. (*Aurantium olysiponense*, Tourne; *Citrus dulcis*, Pers.); on the other hand, the British Pharmacopœia recognizes bitter orange peel in two forms, the fresh and the dried, under the respective names of Aurantii Cortex Recens, fresh bitter orange peel, and Aurantii Cortex Siccatus, dried bitter orange peel; but the orange peel which is called sweet by the U. S. Pharmacopœia—i.e., *Citrus Aurantium*—is termed *C. Aurantium* var. *Bigaradia*, bitter orange peel, by the British authority.

This very interesting genus is composed of small evergreen trees, with ovate or oval-lanceolate and shining leaves, odoriferous flowers, and fruits which usually combine beauty of color with a fragrant odor and grateful taste. They are all natives of warm climates. Though the species are not numerous, great diversity exists in the character of the fruit; and many varieties, founded upon this circumstance, are noticed by writers. In the splendid work on the natural history of the *Citrus* by Risso and Poiteau, 169 varieties are described under the eight following heads: 1, sweet oranges, 2, bitter and sour oranges, 3, bergamots, 4, limes, 5, shaddocks, 6, lumes, 7, lemons, and 8, citrons. Of these it is difficult to decide which have just claims to the rank of distinct species and which must be considered merely as varieties. Those employed in medicine may be arranged in two sets, of which the orange, *C. Aurantium*, and the lemon, *C. medica*, are respectively the types, the former characterized by a winged, the latter by a naked or nearly naked petiole. The form and character of the fruit, though not entirely constant, serve as the basis of subdivisions. *C. Decumana*, which yields the shaddock, agrees with *C. Aurantium* in the form of its petiole.

Citrus Aurantium, Willd., *Sp. Plant.* iii. 1427; B. & T. 51.—The orange tree grows to the height of about thirty feet. Its stem is rounded, much branched, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green color. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with volatile oil, and, when rubbed between the fingers, are highly fragrant.

Their footstalks are about an inch long, and have wings or lateral appendages. The flowers, which have a delightful odor, are large, white, and attached by short peduncles, singly or in clusters, to the smallest branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct groups, and support yellow anthers. The germen is roundish, and bears a cylindrical style, terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange color, and divided internally into a number of vertical cells, each containing from two to four seeds, surrounded by a pulp. The rind of the fruit consists of a thin exterior layer, abounding in vesicles filled with a fragrant volatile oil, and of an interior one, which is thick, white, spongy, insipid, and inodorous. There are two varieties of *C. Aurantium*, considered by some as distinct species. They differ chiefly in the fruit, which in one is sweet, in the other is sour and bitterish and often has a darker and rougher rind. The first retains the original title, the second (the Seville orange) is called *Citrus vulgaris* by De Candolle, and *C. Bigaradia* by Risso. A variety of the orange, called the Mandarin Orange (*Citrus Bigaradia sinensis* or *C. Bigaradia myrtifolia*), which is probably a native of China, but cultivated in Sicily, the south of Italy, and Florida, bears a fruit much smaller than the common orange, round, but flattened above and below, with a smooth, thin, delicate rind, and a very sweet delicious pulp. A volatile oil is obtained from the rind by expression, of a yellow color, a very bland agreeable odor, different from that of the orange or lemon, and a not unpleasant taste, like that of the rind. When freed from coloring matter by distillation, it was found by M. S. de Luca to be a pure hydrocarbon, with the formula C₁₀H₁₆. (*J. P. C.*, 3e sér., xxxiii. 52.) This constituent is now recognized as *d-limonene*.

This beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage, has been applied to numerous purposes of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after its first settlement, and is now found in every civilized country where the climate is favorable. The fruit is brought to us chiefly from California, Florida, Southern Europe, and the West Indies. The Florida and Havana oranges are the sweetest. A seedless variety termed the *navel orange* is rapidly replacing all others in cultivation.

Various parts of the plant are used medicinally. The leaves, which are bitter and aromatic, are employed in some places in the form of infusion as a gently stimulant diaphoretic. They yield by distillation with water a volatile

oil, which is said to be often mixed by the distillers with the oils obtained from the flowers and unripe fruit. In regard to polarized light it has a rotary power to the left, which is considerably weakened by the prolonged action of heat. (Chautard, *J. P. C.*, 3e sér., xlv, 28.) The fresh flowers may be kept for some time by mixing them well with half their weight of sodium chloride, pressing the mixture in a suitable jar, and keeping it well closed in a cool place. They were formerly recognized by the U. S. P. under the name of *Aurantii Flores*, and were officially described as "about half an inch (12 mm.) long; calyx small, cup-shaped, five-toothed; petals five, oblong, obtuse, rather fleshy, white and glandular-punctate; stamens numerous, in about three sets; ovary globular, upon a small disk, with a cylindrical style, and a globular stigma; odor very fragrant; taste aromatic and somewhat bitter." *U. S.* 1880. The dried flowers are used on the continent of Europe as a gentle nervous stimulant, in the form of infusion, two drachms to the pint of boiling water, taken in the dose of a teacupful. The flowers should be dried in the shade, at a temperature between 24° C. (75° F.) and 35° C. (95° F.).

An oil is obtained also from the flowers by distillation, which is called *oil of neroli*, and is much used in perfumery, and in the composition of *liqueurs*. It is an ingredient of the famous Cologne water. That obtained from the flowers of the Seville or bitter orange (*C. vulgaris*) is deemed the sweetest. It was introduced into the Edinburgh Pharmacopœia, with the title of *Aurantii Oleum*, to serve for the preparation of orange flower water. Soubeiran considers this oil rather as a product of the distillation than as pre-existing in the flowers. The fact may thus be explained that orange flower water made by dissolving even the finest neroli in water has not the precise odor of that procured by distillation from the flowers.

The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning-lathe, are sometimes employed to maintain the discharge from issues. They are preferred to peas on account of their agreeable odor, and by some are thought to swell less with the moisture; but this is denied by others, and it is asserted that they require to be renewed at the end of twenty-four hours. These fruits are sometimes found in commerce under the name of *orange berries*. They are of a grayish or greenish-brown color, fragrant odor, and bitter taste, and are said to be used for flavoring cordials. A volatile oil is obtained from them by distillation, known to the French by the name of *essence de petit grain*, and employed for similar purposes with that of the flowers. The oil, however, which now goes by this name is said to be distilled from the leaves, and those of the bitter orange yield the best. The oils from the unripe and the ripe fruit have a rotating power to the right, the latter much

greater than the former; and this property might serve to distinguish them from the oil of the leaves. Several of the oils from the *Rutaceæ* deposit a crystalline substance, differing from camphor. (Chautard.) The juice of the Seville orange is sour and bitterish, and forms with water a refreshing and grateful drink in febrile diseases. It is employed in the same manner as lemon juice, which it resembles in containing citric acid, though in much smaller proportion. The sweet orange is more pleasant to the taste, and is extensively used as a light refrigerant article of diet in inflammatory diseases, care being taken to reject the membranous portion. The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, as we pare an apple. When the object is to use the fresh rind for certain pharmaceutical purposes, as for the preparation of the *confection of orange peel*, it is best separated by a grater, carefully avoiding the grating of the white portion which contains the bitter principle. The dried peel sold in the shops is usually that of the Seville orange, and is brought chiefly from countries adjacent to the Mediterranean.

Properties.—Orange peel has a grateful aromatic odor, which depends upon the volatile oil contained in its vesicles, and a warm bitter taste. Bitter orange peel occurs "in narrow, thin bands, or in quarters; epidermis of a brownish-green color; outer layer with numerous oil reservoirs; inner layer spongy, light yellowish-brown; odor fragrant; taste aromatic and bitter." *U. S.* The Br. Pharmacopœia requires that the outer surface both of the fresh and of the dried bitter orange peel shall be of a deep orange-red color, and rough and glandular. As lemon peel is sometimes substituted for orange peel, a means of distinguishing between them has been devised by E. G. Clayton (*An.*, xix, 134), which is to touch small fragments of peel with a glass rod dipped in hydrochloric acid. Orange peel is colored a rich, dark green; the color of lemon peel is unaffected. The sweet peel is described officially as having the "outer surface orange-yellow, with numerous oil reservoirs; odor highly fragrant; taste pungently aromatic." *U. S.* Both orange peels yield their sensible properties to water and alcohol. The bitter principle, *hesperidin*, $C_{22}H_{32}O_{12}$, was discovered by Lebreton in 1828, but its character as a glucoside was first established by Hilger and Hoffmann. (*Ber. d. Chem. Ges.*, 9, 26, 685.) Treated with diluted acids it yields *hesperetin*, $C_{16}H_{14}O_6$, and glucose. It is crystalline (fusing point 250° to 251° C.), and may be prepared by Paterno and Briosi's process, as follows: The cut and bruised oranges are covered with diluted alcohol, solution of potassium hydroxide added in excess, the liquor filtered after two days, an impure hesperidin precipitated by hydrochloric acid; the precipitate is boiled with acetic acid for ten minutes, and, after cooling, filtered from the resinous mass

left. The hesperidin gradually separates from the filtrate upon standing, in white fine needles. From 4000 oranges about 6 ounces av. of the principle were obtained. (*Ber. d. Chem. Ges.*, 1876, 250-252.) Tanret found in the rind of the bitter orange, 1, a crystalline acid, $C_{44}H_{72}O_{14}$; 2, a non-crystalline resinous body; 3, *hesperidin*; 4, *isohesperidin*, a crystalline glucoside isomeric with hesperidin; 5, *aurantiamarin*, another glucoside to which, in part, the bitterness of the peel is due. (*P. J.*, 1886, 839.) Orange peel contains also albumen, gum, resin, a trace of fixed oil, volatile oil, and a principle resembling tannin in its action on salts of iron. The bitter principles are much more abundant in the white spongy inner portion of the peel than in the outer yellowish layer. The volatile oil, *Oleum Aurantii Corticis*, U. S., may be obtained by expression from the fresh grated rind, or by distillation with water. It is imported into the United States in tinned copper cans. It has properties resembling those of the oil of lemons, but spoils more rapidly on exposure to the air, acquiring a terebinthinate odor. The perfumers use it in the preparation of Cologne water, and for other purposes; and it is also employed by the confectioners. According to Imbert-Gourbeyre, persons who are much exposed to the inhalation of the oil of bitter oranges are apt to be affected with cutaneous eruptions, and various nervous disorders, as headache, tinnitus aurium, oppression of the chest, gastralgia, want of sleep, and even muscular spasm. (*Ph. Ch.*, Feb. 1854, 128.)

Uses.—Bitter orange peel is a mild tonic, carminative, and stomachic; the sweet is simply aromatic; but neither is much used alone. They are chiefly employed to communicate a pleasant flavor to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. They are a frequent and useful addition to bitter infusions and decoctions, such as those of gentian, quassia, calumba, and Peruvian bark. It is obviously improper to subject orange peel to the action of heat, as the volatile oil is thus driven off. Violent colics, convulsions, and even death have been caused in children by eating large quantities of the rind. When orange peel is used simply for its agreeable flavor, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

Dose, from half a drachm to a drachm (2 to 3.9 Gm.).

AURI ET SODII CHLORIDUM. U. S.

GOLD AND SODIUM CHLORIDE

(ău'ri ět sô'di-i chlô'rj-dŭm)

"A mixture of equal parts, by weight, of anhydrous Gold Chloride [$AuCl_3 = 301.24$] and anhydrous Sodium Chloride [$NaCl =$

58.06], representing not less than 30 percent. of metallic gold. It should be kept in well-stoppered, amber-colored vials." U. S.

Chlorure d'Or et de Sodium, *Fr. Cod.*; Chloraurate de Soude, *Fr.*; Natriumgoldchlorid, *G.*; Cloruro di oro e sodio, *It.*

Gold and sodium chloride may be prepared by dissolving gold in nitrohydrochloric acid, evaporating the solution to dryness, weighing, and dissolving the dry mass in eight times its weight of distilled water. To this solution a weight of pure decrepitated common salt equaling that of the dry gold chloride is added, previously dissolved in four parts of water. The mixed solutions are then evaporated to dryness, being in the meantime constantly stirred with a glass rod. A process for making this salt from gold coin without requiring the preliminary purification necessary in the above process may be found in *Proc. A. Ph. A.*, 1882, p. 311. (See Kebler's paper, *A. J. P.*, 1900, 325; and one by Averkief, *Chem. News*, 1903, 84.)

Properties.—The pure crystallized salt, $AuCl_3 \cdot NaCl \cdot 2H_2O$, is of a golden-yellow color, and is in the form of prismatic crystals. The mixture of the U. S. P. is described as "an orange-yellow powder, odorless, having a saline and metallic taste, and deliquescent when exposed to damp air. The compound is very soluble in water, and at least one-half of it should be soluble in cold alcohol. When exposed to a red heat, it is decomposed, and metallic gold is separated. A fragment of the compound imparts a persistent, intensely yellow color to a non-luminous flame. Its aqueous solution has a slightly acid reaction, and yields with silver nitrate T.S. a white precipitate insoluble in nitric acid and soluble in ammonia water. On bringing a glass rod moistened with ammonia water close to a portion of Gold and Sodium Chloride, no white fumes should make their appearance (absence of *free hydrochloric acid*). If 0.5 Gm. of Gold and Sodium Chloride be dissolved in 25 Cc. of water, in a porcelain dish, the solution made alkaline by the addition of 5 Cc. of potassium hydroxide T.S., and, after the addition of 5 Cc. of solution of hydrogen dioxide, heated for about one hour on a water-bath, a precipitate of metallic gold will be obtained, which, when washed with water slightly acidulated with hydrochloric acid, dried, and ignited, should weigh not less than 0.15 Gm. (corresponding to at least 30 percent. of metallic gold). The filtrate from the precipitated gold should not be affected by hydrogen sulphide T.S., nor, after being supersaturated with ammonia water, by ammonium sulphide T.S. (absence of *metallic impurities*)." U. S.

Uses.—The precise action of this salt upon the system is not known, but it is thought to affect the general nutrition, and to be therefore alterative. By many gynæcologists it is believed to have a specific direction to the genital organs, and it is used in *hysteria*, *ovarian irritation* and *neuralgia*, *chronic ovaritis*, and even *chronic uterine inflammation*. It has also been

commended in *syphilis*, *chronic rheumatism*, *diabetes mellitus*, and other chronic disorders affecting nutrition. The double salt of gold and sodium chloride has recently been very largely used in the treatment of the *alcoholic habit*. It is believed to be the basis of the notorious "*Keeley cure*," which, according to the best information obtainable, seemingly reliable, consists in chief part of the administration of ascending doses of the double chloride, with hypodermic injections in the interim (one every three hours) of very minute doses of atropine and strychnine. It would seem certain that no medication can suffice for moral reformation, but there is considerable evidence to show that the treatment just spoken of, by toning up the nervous system and bringing about a general increase of nutritive tone, may aid those who are determined upon reform.

Dose, one-twelfth to one-quarter of a grain. (0.005 to 0.016 Gm.).

AURUM

GOLD

(äur'üm)

Or, *Fr.*; Gold, *G.*; Oro, *It.*, *Sp.*

The preparations of gold were introduced into medical practice in 1810 by Chrestien of Montpellier. They have been especially recommended in various chronic diseases of the nervous system and skin, also in inveterate constitutional syphilis and allied disorders. The U. S. Pharmacopœia recognizes one preparation (see p. 219). For a discussion of the various non-official preparations which have been used in medicine, see *Gold*, PART II.

BALSAMUM PERUVIANUM. U. S., Br.

BALSAM OF PERU

(bäl'sä-müm pë-rü-vi-ä'nüm)

"A balsam obtained from *Toluifera Pereira* (Royle) Baillon (Fam. *Leguminosæ*)."
"A balsam exuded from the trunk of *Myroxylon Pereira*, *Klotzsch*, after the bark has been beaten and scorched." *Br.*

Balsamum Peruvianum Nigrum, Balsamum Indicum; Baume des Indes, Baume de Pérou noir, Baume de Sonsonate, *Fr.*; Balsamum peruvianum, *P. G.*; Peruvianischer Balsam, Indischer Balsam, Perubalsam, *G.*; Balsamo peruviano, Balsamo del Peru, *It.*; Balsamo del Peru liquido, Balsamo de San Salvador, Balsamo negro, *Sp.*

De Candolle and other botanists considered that the genera *Myroxylon* and *Toluifera* of Linnæus are not distinct from *Myrospermum* of Jacquin, but it is now generally recognized that the two Linnæan genera are, taken together, entitled to rank as a single genus. To this the title of *Myroxylon* has been generally applied by botanists following Bentham and Hooker, but Baillon (*Natural History of Plants*, vol. ii. 366) seems to be in accord with the generally accepted rules of botanical nomenclature in preferring the name *Toluifera*. In regard to the

species now under consideration there has been much discussion, and although the plant is now well known botanically, botanists are not agreed as to its specific distinctness, Ruiz (*Flora Peruviana*), Carson (*A. J. P.*, 1860, p. 297), Baillon, and others believing it to be identical with the tree which yields balsam of Tolu. Flickiger and Hanbury (*Pharmacographia*, 2d ed., 205) give the following points of difference: in *M. Pereira* the branches come off near the ground, the calyx is widely cup-shaped, and shallow, the racemes loose, 6 to 8 inches long, and the legume much narrowed at its base; while in *M. toluifera* the trunk does not branch for 30 or 40 feet, the calyx is rather tubular, the racemes dense and 3 to 4½ inches long, the legume scarcely narrowed at the base. Besides the official species, there are others of the genus which possess medicinal virtues, and have been more or less employed. (See 14th ed. U. S. D.) The pod of *M. frutescens*, Jacq., growing in Trinidad, is popularly used in that island as a carminative, and externally, in the form of a tincture, as a lotion in rheumatic pains, and by incisions in the stem a small quantity of balsamic juice is obtained not distinguishable from balsam of Tolu. (*P. J.*, Sept. 1862, p. 108.) Another species is known in Paraguay under the name of *quino-quino*, the bark of which is used, in powder and decoction, as a remedy in wounds and ulcers, and from the trunk of which a juice is obtained which in its concrete state closely resembles dried balsam of Peru. (*P. J.*, Oct. 1862, p. 183.) A product of *T. peruvianum*, sometimes known as *Brazilian balsam* or as *Oleo-balsam* has been offered for sale as genuine Peru balsam. In bulk it is of a dark brown color, but in thin layers it is dark red. Its odor is smoky, feebly fragrant; its taste slightly pungent, leaving a choking, disagreeable, persistent feeling. It is entirely soluble in ether and in rectified spirits. It also mixes with castor oil in all proportions, and forms with carbon disulphide a clear light brown solution with residue, also a deposit, in its chloroform solution, which becomes a powdery precipitate upon standing. At 17° C. its specific gravity is 1.031. Its general constitution is very similar to that of balsam of Peru, containing volatile oil, myroxylon, cinnamic and tannic acids, and resin. (*P. J.*, 3d ser., xi. 818.) It is especially to be distinguished from Peru balsam by its behavior with sulphuric acid. When Peru balsam is treated with sulphuric acid, and cold water poured upon it, a beautiful violet color is imparted to the surface, and the whole mass has a bright shade. The same procedure yields with the oleo-balsam a gray mass. For further information see *P. J.*, xv. 771.

Toluifera Pereira; *Myroxylon Pereira*, *Klotzsch*; *Myrospermum Pereira*, *Royle et Auctores*; and "*Myrospermum of Sonsonate*," *Periera*. This is a handsome tree, with a straight, round, lofty stem, a smooth ash-colored bark, and spreading branches at the top. The leaves are alternate, petiolate, and unequally pinnate.

The leaflets are from five to eleven, shortly petiolate, oblong, oval-oblong, or ovate, about three inches long by somewhat less than an inch and a half in breadth, rounded at the base, and contracting abruptly at top into an emarginate point. When held up to the light they exhibit, in lines parallel with the primary veins, beautiful rounded and linear pellucid spots. The common and partial petioles and midribs are smooth to the naked eye, but when examined with a microscope are found to be furnished with short hairs. The fruit, including the winged footstalks, varies from two to four inches in length. At its peduncular extremity it is rounded or slightly tapering; at the top enlarged, rounded, and swollen, with a small point at the side. The mesocarp, or main investment of the fruit, is fibrous, and contains in distinct receptacles a balsamic juice, which is most abundant in two long receptacles or vittæ, one upon each side. The yellowish-white beans yielded to Rother (*P. J.*, xv. 244) two per cent. of coumarin; the husks, a brown, extremely bitter, somewhat acrid resin. A gum-resin exudes in small quantities from the trunk of the tree, which, though containing, besides gum and resin, a small proportion of volatile oil, is distinct from the proper balsam, and yields no cinnamic acid. (Attfeld, *P. J.*, Dec. 1863.) The valuable wood of the tree resembles mahogany.

This tree grows in Central America, in the State of San Salvador, upon the Pacific coast. It is found in the wild forests, singly or in groups, but the trees are owned by individuals. Charles Dorat states that it is never found at a greater height on the mountains than one thousand feet, that it begins to be productive after five years, and continues to yield for thirty years or more, and that the aroma of its flower is perceived at the distance of one hundred yards. (*A. J. P.*, xxxii.) The balsam is collected by the aborigines, on lands reserved to them, within a small district denominated the Balsam Coast, extending from Acajutla to La Libertad. Early in November or December the bark is beaten on four sides of the trunk, so as to separate it from the wood without breaking it, intermediate strips being left sound, in order not to destroy the life of the tree. The bruised bark soon splits, or cuts are made in it. Five or six days after the beating the injured surface is set on fire, and about a week later the bark, if it has not fallen off spontaneously, is removed. The juice now begins to exude freely from the exposed wood, which the natives cover with rags. The latter, when saturated, are boiled in water in large jars, and the liquid allowed to stand, whereupon the water rises to the top, and is poured off, leaving the balsam, which is put into calabashes or bladders. Seven to ten days later a second flow of balsam occurs, and is secured as before. Subsequently the exposed parts are scraped or otherwise wounded, and a third balsam is obtained. These three grades of balsam are said to be known re-

spectively as *Tagauzonte*, *balsam de trapo*, *balsamo de contrapique*. The balsam is then taken for sale to the neighboring towns, where it is purified by subsidence and straining and put into jars or metallic drums for exportation. The destroyed bark is said to renew itself in two years, so that by care a tree can be worked for a long time; two pounds is stated to be the average yearly yield. In 1861 the tree was introduced in Ceylon with complete success.

A substance called *white balsam* (*Balsamo blanco*) is procured from the fruit. This has been confounded with the balsam of Tolu, but is wholly distinct. It is of a semi-fluid or soft-fluid consistence, somewhat granular, and, on standing separates into a white, resinous, crystalline deposit, and a superior, translucent more fluid portion. The odor, though quite distinct from that of the balsams of Tolu and Peru, is not disagreeable. Stenhouse has obtained from it a peculiar resinous body, readily crystallizable, and remarkably indifferent in its chemical affinities, which he denominated *myroxocarpin*. (*P. J.*, x. 290.) Tschirch (*Harze und Harzbehälter*, 1900, p. 166) gives the compound the name *myroxoresene*, and the formula, $C_7H_{10}O$. Dorat, however, denies that the white balsam is produced by the same tree, or in the same vicinity.

Another substance obtained from the same tree, and much used in Central America, is a tincture of the fruit made by digesting it in rum. It is called *balsamito* by the inhabitants, and is said to be stimulant, anthelmintic, and diuretic. It is also used as an external application to gangrenous or indolent ulcers, and as a wash to the face to remove freckles. According to Dorat, the balsamito is not the tincture, but an alcoholic extract of the young fruit. Neither this nor the white balsam reaches the markets of this country.

Balsam of Peru was named from its place of exportation, and it was long thought to be a product of Peru. It is now shipped partly from the Pacific coast, and partly from the Balize or other Atlantic ports, whither it is brought across the country. It was Guibourt who first made known the fact of its exclusive production in Central America. As imported, it is usually in tin canisters, with a whitish scum on its surface, and more or less deposit, which is dissolved with the aid of heat.

Properties.—Balsam of Peru is viscid like syrup or honey, of a dark reddish-brown color, a fragrant odor, and a warm bitterish taste, leaving, when swallowed, a burning or pricking sensation in the throat. When exposed to flame it takes fire, diffusing a white smoke and fragrant odor. Containing resin, volatile oil, and both benzoic and cinnamic acids, it is properly considered a balsam, though probably somewhat altered by heat. "A viscid liquid of a dark brown color; free from stringiness or stickiness; transparent and reddish-brown in thin layers; of an agreeable vanilla-like odor and

a bitter, acrid taste, with a persistent after-taste. When swallowed, it leaves a burning sensation in the throat. It does not harden on exposure to the air. Specific gravity: 1.140 to 1.150 at 25° C. (77° F.). Completely soluble in absolute alcohol, chloroform, and glacial acetic acid; only partially soluble in ether and petroleum benzin; soluble in 5 parts of alcohol, with not more than a slight opalescence." *U. S.* Boiling water extracts the acid. The oily liquid which separates on agitating Peru balsam with potassium or sodium hydroxide, called *Peru balsam oil* by Stolze, and *cinnamein* by Frémy, may be separated by fractional distillation into three portions,—viz., *benzyl alcohol*, C_7H_8O , passing over at about 200° C. (392° F.); *benzyl benzoate*, $C_7H_5O_2.C_7H_7$, the principal portion boiling at 303° to 304° C. (577.5° to 579° F.); and *benzyl cinnamate*, $C_9H_7O_2.C_7H_7$, passing over at about the boiling point of mercury. The crude oil likewise contains small quantities of free cinnamic and benzoic acids, resulting from the decomposition of the benzylic ether by the alkali used in separating it. According to Kraut (*Ann. Ch. Ph.*, 153, p. 129), the benzyl cinnamate constitutes nearly 60 per cent. of the balsam; but Trog (*A. Pharm.*, 1894, 70-98) states that it is the benzyl benzoate which makes up the bulk of the oily portion and amounts to from 63 to 64 per cent. Tschirch (*loc. cit.*) states that in the sample of Peru balsam investigated by him benzyl benzoate was the main constituent, but small amounts of benzyl cinnamate were also present, and he considers that the relative proportions of the two esters may vary greatly in different samples of the balsam. The odor of the balsam Tschirch considers to be due to the *peruvial*, $C_{13}H_{22}O$, discovered by Thoms.

Peru balsam appears to contain only a single resin, yielding, by analysis, 66.3 to 67.25 per cent. of carbon, and 6.22 to 6.32 per cent. of hydrogen (Kraut, *loc. cit.*). This resin separated from the alkaline solution of the balsam by hydrochloric acid is brown, has a faint odor of vanilla, and when fused with potash yields protocatechuic acid, together with a little benzoic acid. Tschirch has studied this resin and finds it to be the *cinnamic ester* of an alcoholic body called *peru-resino-tannol*, with the formula $C_8H_5.CH.COOC_{16}H_{33}O_4$. The tree also exudes a gum-resin, which, according to Attfield (*P. J.*, 1864, p. 248), contains 77.4 per cent. of a resin, and is non-aromatic, devoid of cinnamic acid, and entirely distinct from balsam of Peru. The leaves of the tree contain a fragrant oil. Like benzoin, balsam of Peru appears to be a pathological product.

The balsam is said to be adulterated in Europe (especially at Bremen) with castor oil, copaiba, Canada turpentine, etc. (*P. J.*, xii. 549), and a factitious substance has been sold in this country for the genuine balsam, prepared by dissolving balsam of Tolu in alcohol. This may be distinguished by its taking fire readily and burning with a blue flame. (*N. Y. J.*

Pharm., i. 133.) The British Pharmacopœia gives the following tests. "1 volume is soluble in 1 volume of *alcohol* (90 per cent.), but on the further addition of 2 or more volumes of the *alcohol*, the mixture becomes turbid. Specific gravity between 1.137 and 1.150. 10 drops triturated with 0.4 gramme of *lime* produce a permanently soft mixture (absence of copaiba and resins); and this, on being warmed until all volatile matter is given off and until charring commences, gives no fatty odor (absence of castor oil and other fatty oils). It should not diminish in volume when shaken with an equal bulk of *water* (absence of ethylic alcohol). About 40 per cent. of resin should separate when one part of the Balsam is treated with three parts of *carbon bisulphide*; and the clear supernatant liquid should be of a pale brown color with only a slight fluorescence (absence of gurjun balsam). If 5 grammes of the Balsam be shaken with 5 cubic centimetres of a solution of *sodium hydroxide* of specific gravity 1.16, and then washed with three successive quantities, each of 15 cubic centimetres, of Purified Ether, and the Ether removed, the residue (after cautious drying until the loss, in two weighings at 5 minutes' interval, does not exceed one centigramme) should weigh between 2.85 and 3 grammes. To this weighed residue 20 cubic centimetres of *normal volumetric alcoholic solution of potassium hydroxide* and 40 cubic centimetres of *alcohol* (90 per cent.) are to be added and the whole saponified under a reflux condenser for one hour. Thus treated, the residue above specified should combine with from 11.9 to 12.8 cubic centimetres of the *normal volumetric alcoholic solution of potassium hydroxide* (presence of a sufficient proportion of cinnamein). The amount of uncombined alkali may be determined in the usual way by means of titration with the *volumetric solution of sulphuric acid*." *Br.* For additional tests, see *Proc. A. Ph. A.*, 1894, 903; also 1895, 866, and *D. C.*, 1898, 60. A method of detecting castor oil, proposed by Wagner, is to expose a small portion of the suspected balsam to distillation until somewhat more than one-half has passed, to shake the distillate with baryta water, to remove by means of a pipette the layer of oil floating on the surface, and to shake this with a concentrated solution of sodium bisulphite. If castor oil be present, the liquid will immediately become a crystalline mass. (*A. J. P.*, xxx. 570.) The official tests of purity are as follows: "Water, when agitated with the Balsam, shows an acid reaction to blue litmus paper. If 10 drops of the Balsam be triturated with 20 drops of sulphuric acid, a tough, homogeneous, brownish-red mass should result, which, when washed with cold water, should develop a violet color upon its surface, and, when drained, be converted into a brittle resinous mass (absence of *fixed oils*). If 1 Gm. of the Balsam be shaken with 5 Cc. of petroleum benzin, the mixture warmed on a water-bath for ten minutes, and a sufficient quantity

of the solvent added to replace loss by evaporation, then if 2 Cc. of the benzin solution be evaporated, and treated with a drop of nitric acid (sp. gr. 1.42), a permanent green or bluish-green color should not be produced (absence of *rosin*). The remaining 3 Cc. of the benzin solution when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000) should not be colored green or bluish-green (absence of *rosin*, *turpentine*, *storax*, *fatty oils*, etc.). On mixing the Balsam with half its volume of calcium hydroxide and heating for half an hour on a water-bath, a solid mass should not be formed (absence of *rosin*, *storax*, or *copaiba*). If 1 Gm. of the Balsam be dissolved in 100 Cc. of alcohol and 1 Cc. of phenolphthalein T.S. be added, not more than 2 Cc. of half-normal alcoholic potassium hydroxide should be required to produce a pink color (limit of *acid resins*). Mix 3 Gm. of the Balsam with 30 Cc. of sodium hydroxide T.S. and shake the mixture for a few minutes with 60 Gm. of ether. Transfer 51.5 Gm. of the ether-solution to a flask and evaporate to dryness. The residue, when dried to constant weight by a gentle heat, should weigh not less than 1.4 Gm. (presence of at least 56 percent. of *cinnamein*). If this residue be dissolved in 25 Cc. of alcohol, then mixed with 25 Cc. of half-normal alcoholic potassium hydroxide V.S., and heated carefully during half an hour on a water-bath, it should require not more than 13.2 Cc. of half-normal hydrochloric acid V.S. to exactly neutralize the liquid, 1 Cc. of phenolphthalein T.S. being used as indicator." U. S. Flückiger relies upon the specific gravity, which should be between 1.140 and 1.145, and the *lime test*, in which 10 drops of the balsam are shaken with 6 grains (0.4 Gm.) of slaked lime, forming, if there be no adulteration, a soft mixture, which does not harden. *Grote's test* consists in shaking 3 drops of balsam with 2 Cc. of official ammonia water; if, after standing, the mixture solidifies, *rosin* or other adulterant is present; *benzoin*, *storax*, and certain other substances cannot be detected by this test. (*A. J. P.*, 1881, 302, 361.)

As stated by Trog and others, the percentage of *cinnamein* should approximate 60. The saponification number should be between 235 and 238.

Uses.—This balsam is a warm stimulating stomachic and expectorant, and has been recommended in *chronic catarrhs*, certain forms of *asthma*, *phthisis*, and other *pectoral complaints* attended with debility. As an external application it has been found beneficial in *chronic indolent ulcers* and in *local tuberculosis of skin*, *bone*, *larynx*, etc. It is best administered diffused in water with sugar and the yolk of egg or gum arabic, or in smaller doses dropped on a lump of sugar. When prescribed¹ as an

addition to expectorant mixtures, sufficient mucilage of acacia should be ordered with it to suspend it properly.

Dose, from five to fifteen minims (0.3 to 0.9 Cc.).

BALSAMUM TOLUTANUM. U. S., Br.

BALSAM OF TOLU

(bāl'sa-mūm tō-lū-tā'nūm)

"A balsam obtained from *Toluifera Balsamum* Linné (Fam. *Leguminosæ*)." U. S. "A balsam obtained by making incisions in the trunk of *Myroxylon Toluifera*." Br.

Balsamum Americanum; Baume de Tolu. Baume de Carthagène, Fr.; Balsamum Tolutanum, P. G.; Tolu-balsam, G.; Balsamo Tolutano, Balsamo del Tolu, It.; Bálsamo de Tolu, Sp.

Although Linnæus described this tree as a distinct species, Ruiz, one of the authors of the *Flora Peruviana*, considered it identical with *Myroxylon peruiferum*; but Achille Richard determined that it was distinct, and gave it the specific name of *toluiferum*, which was formerly adopted in both the Br. and U. S. Pharmacopœias. Very properly, however, the revisers of the U. S. P. have returned to the Linnæan name.

The balsam is said to be produced normally in the tree only in young growing tissues such as the young twigs and leaves, and to be formed in the older tissues only as the result of injuries received. It is procured by making V-shaped incisions in the trunk quite through the bark. The juice is received in small calabash cups, which are inserted in slight excavations beneath the point of the two vertical incisions meeting at the lower end; and Weir has seen as many as twenty cups at a time on one tree. The collectors go from tree to tree, emptying the cups into flasks of raw hide. In these skin vessels the juice is taken to the different ports on the river, where it is transferred to tin cans. It is brought from Carthagena in calabashes or baked earthen jars, or in tin or glass vessels.

Properties.—As first imported, balsam of Tolu has a soft tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like *rosin*. It is shining, translucent, of a reddish or yellowish brown color, a highly fragrant odor, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odor while burning. It is entirely soluble in volatile oils. The official description is as follows: "A yellowish-brown, plastic solid, becoming brittle when old, dried, or exposed to cold. It is transparent in thin layers, has a pleasant, aromatic odor, recalling that of vanilla, and a mild, aromatic taste." U. S. "When pressed between pieces of glass with the aid of heat, it exhibits, when examined with a lens, an abundance of crystals." Br. The U. S. Pharmacopœia gives the following tests of purity. "Readily soluble in alcohol, the solution showing an acid reaction

¹ In the case of alleged fatal poisoning in a child six days old, reported by Lohaus (*Th. M.*, March, 1892), it does not seem probable that the Peru balsam was the cause of the symptoms.

to blue litmus paper; also soluble in chloroform and the solutions of the fixed alkalies; almost completely soluble in ether, but nearly insoluble in water and petroleum benzine; partially soluble in carbon disulphide. If 0.5 Gm. of the Balsam be shaken with 25 Cc. of carbon disulphide and allowed to stand for thirty minutes, and the liquid then filtered, the residue obtained by evaporating the filtrate to dryness, when dissolved in glacial acetic acid, should not yield a green color on the addition of a few drops of sulphuric acid (absence of *rosin*). If 1 Gm. of the Balsam be shaken with 8 Cc. of petroleum benzine for five minutes, the supernatant liquid should not be colored green when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000) (absence of *rosin* and *copaiba*). If to 1 Gm. of the Balsam dissolved in 50 Cc. of alcohol, 1 Cc. of phenolphthalein T.S. be added, not less than 4 Cc. nor more than 6 Cc. of half-normal alcoholic potassium hydroxide V.S. should be required to produce a red color (limit of *acidity*); if to this liquid more half-normal alcoholic potassium hydroxide V.S. be added, until the total amount has reached exactly 20 Cc., and the liquid heated in a water-bath for half an hour, and allowed to cool, then not less than 13.2 Cc. nor more than 14.5 Cc. of half-normal sulphuric acid V.S. should be required to neutralize the excess of potassium hydroxide V.S., phenolphthalein T.S. being used as indicator (limit of *saponifiable substances*). U. S. "It is soluble in alcohol (90 per cent.) and the solution has an acid reaction. If 5 grammes are gently warmed with two successive portions of 25 and 10 cubic centimetres of carbon bisulphide, the solution should yield, when evaporated to dryness, a distinctly crystalline residue which should require not less than one-third of its weight of potassium hydroxide for its saponification (presence of a sufficient proportion of benzoates and cinnamates)." Br. The carbon disulphide test is based upon Braithwaite's researches upon spurious balsams of Tolu. (See P. J., 1895, 145; also 1897, 307.)

Boiling water extracts its acid. Distilled with water it affords a small proportion of volatile oil, and, if the heat be continued, an acid matter sublimes. Hatchett states that when dissolved in the smallest quantity of solution of potassium hydroxide it loses its own characteristic odor and acquires that of the clove pink. G. L. Ulex gives as a test of the purity of the balsam, that if heated in sulphuric acid it dissolves without disengagement of sulphurous acid, and yields a cherry-red liquid. (A. Pharm., Jan. 1853.) A modification of this test is that of R. A. Cripps (P. J., xix. 1888) who states that by a comparative test of the suspected balsam with a pure specimen 1 per cent. of storax or other resinous adulterant can be detected. Thirty grammes of the sample are digested in carbon disulphide for fifteen minutes with gentle warmth, the clear liquid decanted, evaporated to dryness, and dissolved in sulphuric acid. A

bright red rose color is produced, remaining rose for a length of time if the balsam be pure, rapidly becoming brown if the balsam has been adulterated. The balsam is a mixture of volatile oil, free acid, and resin. The volatile oil is obtained by distilling the balsam with water, and may amount to a little over 1 per cent. This oil is chiefly *tolene*, $C_{10}H_{16}$, boiling at 170° C. (338° F.), and rapidly hardening by absorption of oxygen from the air. The free acid, according to Deville and Scharling, consists of benzoic and cinnamic acids, which statement has been confirmed by Flückiger (*Pharmacographia*, 2d ed., 204). Buse (*Ber. d. Chem. Ges.*, 1876, 833) has shown that the benzylic esters of these two acids are present in the balsam, the benzyl cinnamate in larger amount.

Tschirch (*Harze und Harzbehälter*, 1900, p. 173) found that the ester mixture in Tolu balsam amounted to 7.5 per cent. against 62 to 64 per cent. in Peru balsam. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0.2 of volatile oil. According to Heaver, the balsam yields by distillation about one-eighth of its weight of pure cinnamic acid. The acid distils over in the form of a heavy oil, which condenses into a white crystalline mass. It may be freed from empyreumatic oil by pressure in bibulous paper, and subsequent solution in boiling water, which deposits it in minute colorless crystals upon cooling. (A. J. P., xv. 77.) A later investigation by Tschirch and Oberländer shows that the resinous portion of the balsam consists of *tolu-resino-tannol* in combination with cinnamic and benzoic acids, the latter in small proportions only. It contains, in addition, 7.5 per cent. of an aromatic, acid, oily liquid, composed mainly of benzyl benzoate, with a little benzyl cinnamate and a trace of vanillin. (A. Pharm., 1894, 599.) A factitious balsam described by R. V. Mattison (A. J. P., 1876, 51) contained 63 per cent. of storax.

Uses.—Balsam of Tolu is a feeble stimulant expectorant; the syrup of Tolu is much used, on account of its agreeable flavor, as the basis of cough mixtures. Old and obstinate *catarrhs* are said to be sometimes greatly relieved by the inhalation of the vapor proceeding from an ethereal solution of this balsam. The best form of administration is that of emulsion, made by triturating the balsam with mucilage and loaf sugar, and afterwards with water.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

Off. Prep.—Syrupus Tolutanus, U. S. (from the tincture), Br.; Tinctura Benzoini Composita, U. S., Br.; Tinctura Tolutana, U. S., Br.

BARIUM

BARIUM

(bār'ŭm)

Ba = 136.04

Baryum, Fr., G.

This is the metal present in the earth baryta. It was first obtained in 1808 by Sir H. Davy,

who described it as a difficultly fusible metal, of a silvery-gray color, decomposing water readily, and considerably heavier than sulphuric acid. When exposed to the air, it instantly becomes covered with a crust of barium oxide. Barium chloride, barium dioxide, and barium carbonate were formerly official.

Barium oxide or *baryta* may be obtained from the native carbonate by intense ignition with carbonaceous matter, or from the native sulphate by ignition with charcoal, which converts it into barium sulphide, subsequent solution of the sulphide in nitric acid, and strong ignition of the nitrate formed, to dissipate the acid. As thus obtained, it is an anhydrous solid, caustic, alkaline, difficultly fusible, and of a grayish-white color. Recently it has been obtained at Niagara Falls by a reaction in which, at the temperature of the electric arc, a small amount of the sulphide obtained by the reducing action of charcoal is made to react with an excess of unchanged sulphate,

Its sp. gr. is about 4. It acts on the animal economy as a poison. When sprinkled with water it slakes like lime, becomes hot, and is reduced to the state of a white pulverulent hydroxide. The same hydroxide is formed in mass when the anhydrous earth is made into a paste with water and exposed to a red heat in a platinum crucible. The excess of water is expelled, and the hydroxide undergoing fusion, may be poured out and allowed to congeal. Barium hydroxide dissolves in water, and forms the reagent called *baryta water*. A boiling saturated solution, as it cools, yields crystals of barium hydroxide containing eight molecules of water of crystallization.

Baryta consists of one atom of barium and one of oxygen. Its chemical formula, is, therefore, BaO . When barium oxide is heated in a current of oxygen or air, it takes up an atom of oxygen and is changed into barium dioxide, BaO_2 . When this is heated somewhat higher, it gives off the extra atom of oxygen and becomes BaO again. This power of taking up oxygen from the air and giving it up at a somewhat higher heat is now utilized on a commercial scale in the Brin process for making oxygen, and it is found that this change from BaO to BaO_2 and back again can be effected at one and the same temperature by simply heating first under pressure and then by exhausting and reducing below the normal atmospheric pressure. Barium dioxide is also of growing importance as the material from which hydrogen dioxide, H_2O_2 is made.¹ *Barium car-*

bonate, BaCO_3 , is the native carbonate, a rare mineral, discovered in 1783 by Withering, in honor of whom it is called *witherite*. It is found in Sweden and Scotland, but most abundantly in the lead mines of Northern England. It occurs usually in grayish, or pale yellowish-gray, fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4.2 to 4.4. It is generally translucent, but sometimes opaque. It effervesces with acids, and, before the blow-pipe, melts into a white enamel without losing its carbon dioxide. It is distinguished from strontium carbonate, with which it is most liable to be confounded, by its greater specific gravity, and by its yielding a light greenish and not a reddish flame upon the burning of alcohol impregnated with its solution in hydrochloric acid. The presence of strontium is indicated by a reddish flame.

When pure, barium carbonate is entirely soluble in hydrochloric acid. Any barium sulphate present is left undissolved. If neither ammonia nor hydrogen sulphide produces discoloration or a precipitate in the hydrochloric acid solution, the absence of aluminum, iron, copper and lead is shown. Lime may be detected by adding an excess of sulphuric acid, which will throw down the *baryta* as a sulphate, and afterwards testing the clear liquid with sodium carbonate, which, if lime be present, will produce a precipitate of calcium carbonate.

Barium carbonate acts as a poison on the animal economy. Its only pharmaceutical use is to prepare barium chloride. (For *Barium Chloride* and *Barium Sulphate*, see PART II.)

drogen dioxide, which remains in solution for a considerable time, if the reaction has taken place in the cold, and an excess of the acid be present. When heated to a bright red heat, Barium Dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium Dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue. If 2.11 Gm. of Barium Dioxide be dissolved, as completely as possible, in ice-cold water to the volume of 25 Cc., with the aid of 7.5 Cc. of phosphoric acid, and 5 Cc. of this solution (corresponding to 0.422 Gm. of the Dioxide), be measured off for assay, it should require not less than 40 Cc. of potassium permanganate decinormal volumetric solution to impart to the liquid a permanent pink tint, corresponding to not less than 80 per cent. of pure Barium Dioxide (each Cc. of the volumetric solution indicating 2 per cent. of the latter)." *U. S.* 1890. Barium dioxide is not used in the practice of medicine.

¹ *Barium Dioxide* or *Peroxide* (BaO_2) was recognized by the U. S. P. of 1890 but was dropped in the 8th decennial revision. It was officially described as "a heavy, grayish-white, or pale yellowish-white, amorphous coarse powder, odorless and tasteless. When exposed to the air, it slowly attracts moisture and carbon dioxide, and is gradually decomposed. Almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hy-

Atropa Belladonna, Willd., *Sp. Plant.* i. 1017; Carson, *Illustr. of Med. Bot.* ii. 19, pl. lxx.; *B. & T.* 193.—The belladonna, or *deadly nightshade*, is an herbaceous perennial, with a fleshy, creeping root, from which rise several erect, round, purplish, branching stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendant, of a dull reddish color, with solitary peduncles, rising from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately deep purple and containing, in two cells, numerous seeds and a sweetish violet colored juice. The calyx adheres to the base of the fruit.

The plant is a native of Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. It grows vigorously under cultivation in this country, and retains all its activity, according to the observations of Alfred Jones. (*A. J. P.*, xxiv. 106.) All parts of it are active. The leaves and roots are directed by the United States and British Pharmacopœias, the latter including the branches, *whitened*, if young, are probably not less efficient. The leaves should be collected in June or July, when the plant is in flower, the roots in the autumn or early in the spring, and from plants three years old or more. Leaves which have been kept long should not be used, as they undergo change through absorption of atmospheric moisture, emitting ammonia, and probably losing a portion of their active nitrogenous matter. It has been affirmed that the finest

looking leaves are to be rejected, as probably being those of cultivated plants, and inferior in strength to the smaller and less sightly leaves of the wild plant. (*A. J. P.*, xxvii. 455.) This is, however, probably an error, as the analyses made by A. W. Gerrard (*P. J.*, xv. 153) show that while the wild belladonna plant contains a little more alkaloid than the cultivated, the difference is not sufficient to be of material consequence. The same investigator found that the leaf yields the alkaloid most abundantly, the root, fruit, and stem being the next in order, and that the period of flowering (between two and four years of age), is the best time for collecting the plant. The dried leaves as they occur in the American market vary remarkably in the percentage of alkaloid; the best are fully equal to the finest English leaves. Specimens which contain much stem or are musty should always be rejected, as weak in active principle. Holmes has found in the English market the root of *Medicago sativa* used as an adulterant. (*P. J.*, 1882.)

Properties.—Officially the leaves are described as "usually of a dull brownish-green color, the leaves much wrinkled and matted together, frequently with the flowering tops intermixed; leaves from 6 to 20 Cm. long, 4 to 12 Cm. broad, broadly ovate, apex acute, margin entire, narrowed into the petiole, upper surface brownish-green, lower surface grayish-green, epidermis more or less papillose, particularly on the under surface; odor distinctly narcotic, especially on moistening; taste somewhat bitter and acrid. The powder is characterized by few hairs and numerous, small, arrow-shaped crystals of calcium oxalate." *U. S.* "The transverse section of the leaf exhibits bi-collateral vascular bundles; the mesophyll contains numerous cells filled with very minute crystals of calcium oxalate." *Br.* The roots occur "in cylindrical or somewhat tapering, longitudinally wrinkled pieces, 1 to 2.5 Cm. thick, the bark somewhat incurved at the edges of roots which have been split before drying; externally pale brownish-gray, dusty or mealy, outer layers of the periderm rather soft, frequently abraded, and thus showing lighter patches; fracture nearly smooth, mealy, and emitting a characteristic puff of dust; internally whitish, the older roots showing medullary rays near the bark; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid. The powder contains relatively few sclerenchymatous fibres and numerous starch grains which are single or 2- to 3-compound, somewhat spherical, and 0.005 to 0.010 Mm. in diameter." *U. S.* The bark of the belladonna root is thick, presenting immediately under the epidermis a dark line composed of from six to eight layers of tubular cells. The bark itself is composed entirely of parenchymatous cells, more or less filled with muller shaped starch grains, which are often united in the cells into compound grains. Bundles of raphides, probably of calcium oxalate, are usually very evident. In va-

rious parts of Europe both the leaves and the root of belladonna are adulterated with the similar products of a *Phytolacca*, which has been variously supposed to be the *Phytolacca decandra* of North America which has become naturalized in Southern Europe; the *P. violacea* of Southwestern Europe, and the *P. abyssinica* which is said to grow on the Riviera. The leaves and general appearance resemble those of belladonna but are to be recognized by their upper surfaces being without hairs and brighter than in the official plant. Moreover, according to E. M. Holmes, the epidermal cells of the true belladonna leaves are irregular, with sinuate walls, and the stomata are rounded; while epidermal cells in the *phytolacca* are polygonal and the stomata elliptical. The dried *phytolacca* root resembles superficially that of belladonna, but according to E. M. Holmes may readily be distinguished by the epidermis not being easily abraded with the finger nail, by the general concentric structure, and by the fact that the rings readily separate into fibrous laminae when the root is broken, the true belladonna root having a short, not at all fibrous, fracture, and even in the oldest roots not separating into laminae. The histology of the *phytolacca* root is also, according to Greenish, characteristic; the raphides are acicular instead of being, as in belladonna, sandy crystals, and the root itself is generally characterized by the alternating distinctly separate rings of wood and bast tissue. *Scopola* root, which is now official, has been largely used by manufacturers of belladonna plasters in the place of belladonna root (see *Scopola*.) Hirtz of Strasburg, inferred from his experiments that the root yields an extract five times stronger than that obtained from the leaves, but did not determine the relative yield of extract, while Lefort obtained from young roots 0.6, from old roots 0.25, and from dried leaves 0.44 per cent. of atropine; Dragendorff obtained 0.66 from dried leaves, and 0.4 per cent. from the roots. (*Jahresb.*, 1874, p. 96.) Both the leaves and root, as well as all other parts of the plant, impart their active properties to water and alcohol. Brandes rendered it probable that these properties reside in a peculiar alkaline principle which he supposed to exist in the plant combined with an excess of malic acid and appropriately named *atropine*. Besides atropine malate, Brandes found in the dried herb two principles, a green resin (chlorophyll), wax, gum, starch, albumen, lignin, and various salts. The alkaloidal principle was first, however, procured in a state of purity by Mein, a German apothecary, who extracted it from the root. Ladenburg (1879 to 1884) exhaustively studied the several sources of atropine and the allied alkaloids that exert a mydriatic action. It is now recognized that there are two alkaloids, *atropine* and *hyoscyamine*, which possess the common formula $C_{17}H_{23}NO_3$, *hyoscyne* or *scopolamine*, $C_{17}H_{21}NO_4$, and in belladonna root, *belladonnine*, $C_{17}H_{21}NO_2$. Of these, atropine occurs in the

Atropa Belladonna and in *Datura Stramonium*, hyoscyamine in these plants and also in *Hyoscyamus niger* and *Duboisia myoporoides*; hyoscyne is found in *Hyoscyamus niger* (and under the name of scopolamine in *Scopola carnolica*), and belladonnine in belladonna root alone. The first of the alkaloids of the formula $C_{17}H_{23}NO_3$, *atropine*, fuses when pure at $115.8^{\circ} C.$ ($240.4^{\circ} F.$), and forms a double gold chloride, fusing at $135^{\circ} C.$ to $137^{\circ} C.$ ($275^{\circ} F.$ to $278.6^{\circ} F.$); the second, the alkaloid known under the several names of *hyoscyamine* and *daturine*, fuses at $108.5^{\circ} C.$ ($227.5^{\circ} F.$), and yields a gold salt fusing at $160^{\circ} C.$ to $162^{\circ} C.$ ($320^{\circ} F.$ to $323.6^{\circ} F.$); on the other hand *hyoscyne* $C_{17}H_{21}NO_4$ has been obtained as yet only in the form of a syrup, but forms a crystalline gold salt, which fuses at $198^{\circ} C.$ to $200^{\circ} C.$ ($388.4^{\circ} F.$ to $392^{\circ} F.$), and is less soluble than the hyoscyamine gold salt; hyoscyne forms readily crystallizable salts, especially the hydrobromide. In *Duboisia myoporoides* (see PART II) the chief alkaloid present seems to be the second of these, and the complete identity of it with the purified alkaloid of hyoscyamus has been established by Ladenburg, both by analysis of the free alkaloid and its salts, and by study of the action of different reagents upon it. Hyoscyamine is more soluble in water and diluted alcohol than is atropine, and, as already stated, forms a gold salt of different fusing point. Its decomposition products under the influence of caustic baryta or hydrochloric acid are the same as those of atropine,—viz., *tropine* and *tropic acid*. Hübshmann (*Schweiz. Zeits. Pharm.*, 1858, 123) and Kraut (*Ann. Ch. Ph.*, 148, 236) both described, under the name of *belladonnine*, a second alkaloid extracted from belladonna root. This *belladonnine* and another alkaloid, *atropamine*, found at times in belladonna root, and obtained from the by-products of the manufacture of atropine, possess the formula $C_{17}H_{21}NO_2$, and are considered as anhydro-atropines. Both bases form varnish-like masses. Merck has isolated a base isomeric with Hesse's atropamine, which has been termed *apootropine*, the salts of which are easily crystallizable. He asserts that atropamine and apootropine are identical. Hesse, on the other hand, denies this assertion. (*Ann. Ch. Ph.*, 271, 10.) For the mode of preparing atropine, and its properties, see *Atropina*, page 212. Dunstan and Ransom have devised processes for isolating the alkaloids from the root and leaves which they assert are simple and accurate. (See *A. J. P.*, 1884, 277; *Proc. A. Ph. A.*, 1886, 392.) A. W. Adams states that only 53 per cent. of the atropine in belladonna leaves can be separated by these processes. (*Am. Drug.*, 1891, 328.) For other assays of belladonna leaves and root, and comments, see Schwickerath (*Ph. Rund.*, 1893, 282); Keller (*Ph. Ztg.*, 1894, 345); Moerk (*A. J. P.*, 1899, 105); La Wall and Pursell (*A. J. P.*, 1899, 394); Puckner (*Ph. Rev.*, 1898, 180, 324; 1902, 457); Bird, (*P. J.*, 1900, 195); Keb-

ler (*Am. Drug.*, 1902, 215); Schmidt (*Ap. Ztg.*, 1900, 13.) The British Pharmacopœia has adopted a process of assay for these alkaloids. (See *Extractum Belladonnæ Liquidum*.) The U. S. P. (8th Rev.) adopted assays for both belladonna leaves and the root which are as follows:

Assay of Belladonna Leaves.—"Belladonna Leaves, in No. 60 powder, *ten grammes*, Chloroform, Ether, Normal Sulphuric Acid V.S., Ammonia Water, Distilled Water, Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., or Iodoeosin T.S., each, *a sufficient quantity*. Place the Belladonna Leaves in an Erlenmeyer flask, and add 50 Cc. of a mixture of chloroform 1 part and ether 4 parts (both by volume). After inserting the stopper securely allow the flask to stand ten minutes, then add 2 Cc. of ammonia water mixed with 3 Cc. of distilled water, and shake the flask well at frequent intervals during one hour. Then transfer as much as possible of the contents of the flask to a small percolator which has been provided with a pledget of cotton packed firmly in the neck and inserted in a separator containing 6 Cc. of normal sulphuric acid V.S. diluted with 20 Cc. of distilled water. When the liquid has passed through the cotton, pack the Belladonna Leaves firmly in the percolator with the aid of a glass rod, and having rinsed the flask with 10 Cc. of the chloroform-ether mixture, transfer the remaining contents of the flask to the percolator, by the aid of several portions (5 Cc.) of the chloroform-ether mixture, and continue the percolation with successive small portions of the same liquid (using in all 50 Cc.). Next, shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid solution into another separator. Add to the chloroform-ether mixture 10 Cc. of sulphuric acid mixture of the same strength as that previously used, agitate well, and again draw off the acid solution into the second separator; repeat this operation once more, drawing off the acid solution as before; introduce into the acid solutions contained in the second separator a small piece of red litmus paper, then add ammonia water until the liquid is distinctly alkaline, and shake out with three successive portions of chloroform 15, 15, and 5 Cc.; collect the chloroform solutions in a beaker, place it on a water-bath containing warm water, and allow the chloroform to entirely evaporate. Dissolve the residue in 3 Cc. of ether, and let this also evaporate completely. To the alkaloidal residue add 3 Cc. of tenth-normal sulphuric acid V.S. and 5 drops of hematoxylin T.S. (or iodoeosin T.S.), then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 3 (the 3 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0287

and this product by 10; the result will be the percentage of total mydriatic alkaloids contained in the Belladonna Leaves." U. S.

Assay of Belladonna Root.—"The method to be employed is identical with that given under Belladonna Leaves, using *ten grammes* of Belladonna Root in No. 60 powder." U. S. W. Will published (*A. Phys.*) in 1888 the results of an investigation undertaken at the request of the Schering manufactory to determine why the proportion of hyoscyamine and atropine in a root seems to vary with the method of working, and reached the surprising conclusion that hyoscyamine can be changed into atropine under a variety of circumstances, such as fusion, action of weak soda solution (even at ordinary temperature), and of ammonia. The conversion of the optically active hyoscyamine into the optically inactive atropine, the alteration of fusing point in the two alkaloids, and of their double gold chloride salts, all confirm the results of the investigation. (*Ber. d. Chem. Ges.*, 1888, p. 1717.) The results were also confirmed by Schmidt. They were at first doubted by Ladenburg, but seem now to be admitted, the two alkaloids being stereo-isomeric, and capable of such change.

Uses.—The action of belladonna upon the system is that of atropine. (See p. 214.) All parts of the plant are poisonous. It is not uncommon, in countries where it grows wild, for children to pick and eat the berries, allured by their fine color and sweet taste. Soon after the poison has been swallowed, its peculiar influence is experienced in dryness of the mouth and fauces, burning in the throat and stomach, great thirst, difficult deglutition, loss of vision, vertigo, and intoxication or delirium, with violent gestures and sometimes fits of laughter, followed by coma. A feeble pulse, cold extremities, subsultus tendinum, deep coma or delirium, and sometimes convulsions, precede death. To obviate the poisonous influence of the belladonna the most effectual method is to evacuate the stomach as speedily as possible, by means of emetics or the stomach tube, and afterwards to cleanse the bowels by purgatives and enemata. The infusion of galls and compound solution of iodine have been recommended as antidotes. Both morphine and pilocarpine are to some extent physiologically antagonistic to atropine, and have been found very useful in belladonna poisoning. (See *B. M. J.*, Feb. 1890.) They should be given hypodermically.

Belladonna has been used as a medicine from early times. The leaves were first employed externally to discuss *scirrhus tumors* and heal *cancerous* and other *ill-conditioned ulcers*, and were afterwards administered internally for the same purpose. Belladonna has acquired considerable credit as a preventive of *scarlatina*,—an application of the remedy first suggested by the author of the homœopathic doctrine,—but it is absolutely devoid of any such power. For further information, see *Atropina*.

The extract is much used locally. Rubbed upon the areola of the breast, it has been found to arrest the *secretion of milk*; upon the abdomen, to relieve the *vomiting of pregnancy*, and other irritations sympathetic with the gravid uterus. In *cardiac diseases* the plaster is often applied with advantage over the heart. The decoction or extract, applied to the neck of the uterus, is asserted to have hastened *tedious labor* dependent on rigidity of the os cervicis; and spasmodic stricture of the urethra, neck of the bladder, and sphincter ani, anal fissures, and painful uterine affections, have been relieved by the local use of the extract, either smeared upon bougies or administered by injection. In the latter mode it has relieved *strangulated hernia*. It is asserted also to be useful in *paraphimosis*. The inhalation of the vapor from a decoction of the leaves or extract has been recommended in *spasmodic asthma*. For this purpose, two drachms of the leaves, or fifteen grains of the aqueous extract, are employed to the pint of water. A much better plan is to smoke the dried leaves in the form of a cigarette or in a pipe. Relief is said to have been obtained in *phthisis* by smoking the leaves, infused when fresh in a strong solution of opium, and then dried.

Belladonna should never be given in substance, but in the form of extract or tincture, or, when accuracy or quickness of action is desired, of atropine. (See *Atropina*.)

Dose, one grain (0.065 Gm.).

BENZALDEHYDUM. U. S.

BENZALDEHYDE

(bên-zāl-đê-hỹ-dũm)

$C_7H_6O = 105.25$

"An aldehyde, produced artificially, or obtained from natural oil of bitter almond or other oils, and containing not less than 85 percent. of pure Benzaldehyde [$C_6H_5.CO.H$]. It should be kept in small amber-colored, well-stoppered bottles." U. S.

Benzol aldehyde; Oleum Amygdalarum Æthereum Sine Acido Prussico; Oleum Amygdalarum Æthereum Artificiale; Aldéhyde Benzolique, Fr.; Benzaldehyd, Künstliches Bittermandelöl, G.

Preparation.—Benzaldehyde is the first in the series of aromatic aldehydes, being the first oxidation product of benzyl alcohol, $C_6H_5.CH_2OH$, and going in turn into the fuller oxidation product, benzoic acid, $C_6H_5.COOH$. It is mainly produced artificially from toluene by the following reactions:

Exposed to the air, benzaldehyde tends to pass by oxidation into benzoic acid, which latter is therefore liable to be found as a contamination of the sample of benzaldehyde if not freshly rectified. Benzaldehyde is officially described as "a colorless, strongly refractive liquid, having a bitter-almond-like odor, and a burning, aromatic taste. Specific gravity: about 1.045 at 25° C. (77° F.). Sparingly soluble in water (1 in 300); soluble, in all proportions, in alcohol, ether, and fixed and volatile oils. Boiling point: 179° to 180° C. (354.2° to 356° F.); optically inactive. If 10 drops of Benzaldehyde, dissolved in a little alcohol, be shaken with a few drops of a strong solution of sodium hydroxide, then with a little ferrous sulphate T.S., and finally mixed with a slight excess of hydrochloric acid, a blue precipitate should not be produced (absence of *hydrocyanic acid*). If the looped end of a piece of clean copper wire be held in a non-luminous flame until it glows, then cooled, and the loop dipped into Benzaldehyde, ignited, and held so that the liquid burns outside of the flame, then if the loop be slowly brought in contact with the lower outer edge of the flame, no green tinge should be discernible (absence of *chlorinated products*). If a small strip of filter paper folded in the form of a taper and saturated with Benzaldehyde be placed in a small porcelain dish, and a clean beaker, moistened on the inner surface with distilled water, be inverted over the smaller dish immediately after igniting the taper, a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate T.S. (absence of *chlorinated products*)." U. S.

Assay.—"Introduce into a tared 150 Cc. flask 10 Cc. of purified kerosene, note the exact weight, add 12 drops of Benzaldehyde, and again note the weight; add 20 Cc. of distilled water with 6 drops of phenolphthalein T.S., and then neutralize the solution exactly by the addition of tenth-normal sodium hydroxide V.S., agitating the flask thoroughly. Add from a burette, gradually, a solution of sodium sulphite (1 in 5), alternating with half-normal hydrochloric acid V.S. from a second burette, until 10 Cc. of the sodium sulphite solution have been added, and enough half-normal hydrochloric acid V.S. to maintain the neutrality of the mixture; after adding a few drops of phenolphthalein T.S., and agitating the flask frequently, allow it to stand two hours to insure a permanent condition of neutrality, and then note the number of cubic centimeters of the half-normal hydrochloric acid V.S. used. Carry out a blank test, identical with the foregoing, except that the Benzaldehyde is omitted, and note the amount of half-normal hydrochloric acid V.S. consumed. Subtract the number of cubic centimeters required in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.0526

Gm. of Benzaldehyde. To find the percentage, multiply the above difference by 0.0526, and this product by 100, and divide by the weight of the Benzaldehyde taken." *U. S.*

Uses.—Benzaldehyde is used as a flavoring agent, in place of the oil of bitter almond, from which it differs in containing no hydrocyanic acid; it is often called artificial or synthetic oil of bitter almond. (See *Oleum Amygdalæ Amaræ*.) It is not poisonous if pure.

Dose, half to one minim (0.03 to 0.06 Cc.).

BENZINUM. U. S.

PETROLEUM BENZIN

(bĕn-zĭ'nŭm)

"A distillate from American petroleum consisting of hydrocarbons, chiefly of the marsh-gas series [C_5H_{12} , C_6H_{14} , and homologous compounds]. It should be carefully kept in well-stoppered bottles or tin cans, in a cool place, remote from lights or fire." *U. S.*

Benzin, Petroleum Ether; Æther Petrolei; Esprit (naphte, Ether) de Pétrole; *Fr.*; Benzinum Petrolei; *P. G.*; Petroleumbenzin, Petroläther, *G.*; Benzina del petrolio, *It.*

This useful product of petroleum was first introduced into the U. S. Pharmacopœia 1880; it is obtained in the process of purifying petroleum by fractional distillation (see *Petroleum*, PART II), and it is defined in the Pharmacopœia as "a transparent, colorless, diffusive liquid, of a strong, characteristic odor, slightly resembling that of petroleum, but much less disagreeable, and having a neutral reaction. Petroleum benzin is highly inflammable, and its vapor, when mixed with air and ignited, explodes violently. Specific gravity: 0.638 to 0.660 at 25° C. (77° F.). Insoluble in water; soluble in about 6 parts of alcohol, and readily soluble in ether, chloroform, benzene, volatile oils, and fixed oils with the exception of castor oil. Boiling point; 45° to 60° C. (113° to 140° F.). If 5 drops of Petroleum Benzin be added to a mixture of 40 drops of sulphuric acid and 10 drops of nitric acid, in a test-tube, the liquid warmed for about ten minutes, and then set aside for half an hour, on diluting it, in a shallow dish, with water, it should not evolve the bitter-almond-like odor of nitro-benzene (difference from, and absence of, *benzene*)." *U. S.* Petroleum benzin must be carefully distinguished from benzene (official in the British Pharmacopœia under the name of *Benzol* and a reagent in the U. S. P.), a product derived from coal tar. Although the U. S. Pharm. gives a test to distinguish an admixture with benzene, this adulteration of petroleum benzin is hardly likely to take place here in the near future, because of the great difference in price. The principal consumption of petroleum benzin at present is in the arts as a solvent, especially as a substitute for oil of turpentine, which it resembles very much in its solvent properties.

In pharmacy it has been used to deprive powdered drugs of their fixed oil by percolation (see *Charta Sinapis*); to obtain volatile oils by percolating the oily drug with the benzin and subsequently evaporating the mixture spontaneously; as a substitute for ether in making oleoresins; and for many other purposes to which it is adapted on account of its powers as a solvent. Petroleum benzin is a good solvent for fats, resins, rubber, and some of the alkaloids.

Dragendorff recommends the rectification of benzin by fractional distillation from lard, collecting the portion which distils below 45° C. We have found petrolatum to be efficient in retaining the impurities in the still. A process is now official for its purification, based upon a method proposed by Geo. M. Beringer (see *Benzinum Purificatum*.)

BENZINUM PURIFICATUM. U. S.

PURIFIED PETROLEUM BENZIN

(bĕn-zĭ'nŭm pŭ-rĭ-fĭ-cā'tŭm)

* "Potassium Permanganate, *ten grammes* [or 154 grains]; Sodium Hydroxide, *two grammes* [or 31 grains]; Sulphuric Acid, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Petroleum Benzin, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]; Water, *a sufficient quantity*.

Add the Acid to *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims] of Water, and when the mixture has become cold, pour it into a bottle having the capacity of about two liters. Add *eight grammes* [or 123 grains] of Potassium Permanganate and agitate until it is dissolved, then add the Petroleum Benzin, in four portions, shaking the liquid after each addition. Allow the liquids to remain in contact for twenty-four hours, shaking the bottle at frequent intervals; then decant the Petroleum Benzin into another bottle of the same capacity, and having dissolved *two grammes* [or 31 grains] of Potassium Permanganate in *two hundred and forty cubic centimeters* [or 8 fluidounces, 55 minims] of Water, in which the Sodium Hydroxide has previously been dissolved, mix the liquids and agitate the mixture frequently during several hours, then decant, repeat the washing with Water, and again decant the Purified Petroleum Benzin." *U. S.*

Purified petroleum benzin was introduced into the U. S. Pharmacopœia (8th Rev.), and is used mainly as a solvent. The official method of purification is based upon the process suggested by Geo. M. Beringer (*A. J. P.*, 1890, 6), and is intended to remove sulphur compounds and other impurities. The official tests are as follows: "On evaporating 10 Cc. of Purified Petroleum Benzin from a piece of clean filtering paper, no greasy stain should remain, and the odor should not be disagreeable or notably sul-

phuretted; no residue should be left upon evaporating Purified Petroleum Benzin from a warmed dish (absence of *heavy hydrocarbons*). When it is boiled for a few minutes with one-fourth its volume of spirit of ammonia and a few drops of silver nitrate T.S., the liquid should not turn brown (absence of *pyrogenous products* and *sulphur compounds*). Purified Petroleum Benzin should have an ethereal or faint petroleum-like odor, and should respond to the tests given under *Benzinum*." U. S.

Uses.—Benzin is not used in practical medicine but has produced in a number of cases sub-acute or chronic poisoning. In the latter class the symptoms have been headache, giddiness, numbness and paræsthesia of the extremities, vomiting, loss of memory, general weakness, especially in the legs, tenderness and pain along the nerve trunks, and progressive anæmia. In acute cases it causes a peculiar intoxication having the appearance at the onset of an attack of hysteria with laughing, tremors, mydriasis, nystagmus, loss of power in the legs and bladder, failing heart action, delirium, coma and death. In nine fatal cases of chronic poisoning by petroleum benzin, Santesson found a wide-spread fatty degeneration affecting especially the liver, kidneys and cardiac muscles.

BENZOINUM. U. S., Br.

BENZOI

(bēn-zō-ī-nŭm)

"A balsamic resin obtained from *Styrax Benzoin* Dryander, and another unidentified species of *Styrax* (Fam. *Styracæ*)." U. S. "A balsamic resin obtained from *Styrax Benzoin*, *Dryand.*; and probably from other species of *Styrax*, *Linn.* Known in commerce as Siam and Sumatra benzoin." Br.

Resina Benzoe, Asa Dulcis; Gum Benjamin; Benjoin, Fr.; Benzoe, P. G.; Benzoëharz, G.; Benzoino, It.; Benjol, Sp.

The botanical source of benzoin was long uncertain. At one time it was generally supposed in Europe to be derived from the *Laurus benzoin* of this country. This error was corrected by Linnæus, who, however, committed another in ascribing the drug to *Croton Benzoë*, a shrub which he afterwards described under the name of *Terminalia Benzoin*. Dryander was the first who ascertained the true benzoin tree to be a *Styrax*. (Lond. Phil. Tran., lxxvii.)

Styrax Benzoin, Willd., Sp. Plant. ii. 623; B. & T. 169.—This is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above, and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang, all on the same side, upon short slender pedicels.

S. Benzoin, Dryand., or *Benjamin-tree*, is a native of Sumatra, Java, Borneo, and other islands in the vicinity. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure and forms the *Sumatra benzoin* of commerce. According to the researches of A. Tschirch (*Journ. Roy. Microscop. Soc.*, 1890), the exudation is purely the result of pathological processes, the plant containing no resin receptacles. The trees, which are either wild or cultivated, are deemed of a proper age to be wounded at six years, when the trunks are usually about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin.

The tree which yields the Siam benzoin is a native of the mainland, and resembles, though specifically distinct from, *Styrax Benzoin*. It is stated to grow in an extremely circumscribed locality, on the bank of the river Mekong, occurring on high ground in clusters of from fifty to sixty trees. According to E. M. Holmes, its leaves are thinner and less distinctly venated than are those of the true *Styrax Benzoin*. In July and August the Siam trees are notched, and from these notches three months later the hardened benzoin is picked out. (See *Kew Bulletin*, 1895.)

Siam benzoin is usually imported in cubical blocks, which take their form from the wooden boxes in which the soft resin has been packed. It is brittle, with a peculiar, vanilla-like fragrance, but bitter taste. It may be a compact mass, containing more or less numerous opaque white tears embedded in a rich amber-colored translucent resin, mixed to a greater or less extent with bits of bark, wood, etc. In some specimens these tears are exceedingly small, in others almost wanting. The finest variety is composed almost entirely of these tears, loosely agglutinated together. *Sumatra benzoin* is sent into commerce chiefly from Acheen in Sumatra. It differs from the Siam varieties in having a much grayer color; the resin is grayish brown, the tears are usually fewer than in the finer variety, and the bits of wood, etc., more abundant. The odor differs from, and is less agreeable than, that of Siam benzoin. *Palembang benzoin* resembles Sumatra benzoin, but is somewhat more transparent, and is stated to yield a larger percentage of benzoic acid. It is also asserted that it can be distinguished by its tincture, when dropped into water, not producing milkiness, but a flocculent deposit. *Penang benzoin* also resembles Sumatra benzoin, but has an odor which is more like that of storax, and it is probably not yielded by the *Styrax Benzoin*; possibly it is the product of one of the Sumatran species, *S. subdenticulata* and *S. Porteriaum*. For an account of the cultivation and collection of benzoin in Sumatra, by L. M. Vonck, see C. D., 1891, 486-488; also D. C., 1891, 258. Lüdy made an investigation of the

bark and wood of a benzoin tree which was brought from Java by Tschirch. He reached the conclusion that benzoin balsam was produced from the tannin of the bark. (*A. Pharm.*, 1893, 43, 95.)

Properties.—Benzoin has a fragrant odor, with very little taste, but when chewed for some time leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds the white spots are very few, or entirely wanting. Benzoin is easily pulverized, and, in the process of being powdered, is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. "In pebble-like bodies or tears, mostly 0.5 to 5 Cm. long and about one-fourth as thick, slightly flattened, straight or curved, yellowish to rusty-brown externally, milky-white on fresh fracture, separate or very slightly agglutinated (Siam Benzoin), or embedded in a dry resinous mass, which varies from reddish-brown to reddish-gray or grayish-brown; opaque or slightly translucent and more or less lustrous (Sumatra Benzoin); brittle, becoming soft on warming, and yielding benzoic acid on sublimation; odor agreeable, balsamic (vanilla-like in the Siam variety); taste slightly acrid. Benzoin is almost wholly soluble in 5 parts of warm alcohol, the solution showing an acid reaction to blue litmus paper; soluble in solutions of sodium or potassium hydroxide. It should not, on incineration, yield more than 2 percent. of ash." *U. S.* "It is almost entirely soluble in alcohol (90 per cent.) and in solution of potassium hydroxide." *Br.* When heated it melts, and emits thick, white, pungent fumes, which excite coughing when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol, and is precipitated by water from the solution, rendering the liquid milky. It yields to boiling water a notable proportion of benzoic acid. Lime water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of other acids. Its chief constituents are resin and benzoic acid, and it therefore belongs to the balsams. The white tears and the brownish connecting medium are said by Stolze to contain nearly the same proportion of acid, which, according to Bucholz, is 12.5 per cent., to Stolze, 19.8 per cent. In a more recent examination by Kopp, the white tears were found to contain from 8 to 10 per cent. of acid, and the brown 15 per cent. (*J. P. C.*, 3e sér., iv. 46.) The resin is of three kinds, one extracted with the benzoic acid by a boiling solution of potassium carbonate in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a little extractive

and traces of volatile oil. Benzoin retards the oxidation of fatty matters, and thus tends to prevent rancidity.

The percentage of soluble matter required to be present by the U. S. Pharm. in benzoin is very high, and if rigidly enforced by the customs would exclude Sumatra benzoin in all but its very finest varieties. Robt. C. Pursel and Willard Graham obtained from 5 commercial varieties of Sumatra benzoin, in the American market, an average of 86 per cent. of soluble matter. (*Proc. Pennsylvania Pharm. Assoc.*, 1902.) John Barclay in England found the average of ten samples to be 69.9 per cent. (*P. J.*, Jan. 1903).

It appears from various researches that benzoin, besides its own characteristic acid, often contains also cinnamic acid, which is found more especially in the white tears. Indeed, Hermann Aschoff obtained from some benzoin of Sumatra a pure cinnamic acid, without any benzoic; and Kolbe and Lautermann, upon examining a specimen of the tears, discovered what they at first supposed to be a peculiar acid, but which on further investigation proved to be a mixture of cinnamic and benzoic acids. H. Beckurts and W. Brueche confirm the statement that Siam benzoin contains no cinnamic acid, which is usually present in Sumatra benzoin. They found the specific gravity from 1.120 to 1.171; ash from 0.05 to 2.38 per cent.; portion insoluble in alcohol from 2.1 to 9 per cent. On the other hand, Tschirch and Lüdy (*A. Pharm.*, 1893, 500) extracted benzoic acid from Siam benzoin by the wet process. They found Sumatra benzoin to contain esters which yielded by saponification 32.9 per cent. of cinnamic acid, the proportion of esters being *benzoeresinol cinnamate*, 7.4 per cent., and *resinotannol cinnamate*, 92.6 per cent., at least 75 per cent. of Sumatra benzoin consisting of cinnamates yielding from 20 to 24 per cent. of cinnamic acid. (See also *A. Pharm.*, 1893, 461; *A. J. P.*, 1893, 223; and *J. P. C.*, 1894, 172). In a later research they found that Siam benzoin did not contain cinnamic acid, either free or in combination as ester. Besides some free benzoic acid and vanillin it contains only esters of benzoic acid. These, on saponification, yielded 38.2 per cent. of benzoic acid, 56.7 per cent. of *isoresinotannol*, and 5.1 per cent. of *benzoeresinol* (Tschirch, *Harze und Harzbehälter*, 1900, p. 155). Benzoin may be rapidly tested for cinnamic acid by heating a small quantity with a little soda and water and warming the filtrate with potassium permanganate, when the odor of bitter almond will be developed. (*A. Pharm.*, 1892, cccxxx.)

Aschoff recommends the following method of detecting cinnamic acid. Boil the benzoin with milk of lime, filter, decompose with hydrochloric acid, and add either potassium dichromate with sulphuric acid, or potassium permanganate, when, if cinnamic acid be present, the odor of oil of bitter almond will be perceived.

Rump (1878) treated Siam benzoin with caustic lime, precipitated the benzoic acid with hydrochloric acid, and agitated the liquid with ether. The latter on evaporating afforded a mixture of benzoic acid and *vanillin*, $C_8H_8O_3$. Subjected to dry distillation, benzoin affords as the chief product benzoic acid, together with empyreumatic products, among which Berthelot has proved the presence (in Siam benzoin) of *styrol*, C_8H_8 . The latter was also obtained in 1874 by Theegarten from Sumatra benzoin by distilling it with water. (*Ber. d. Chem. Ges.*, 1874, p. 727.)

Uses.—Benzoin is stimulant and expectorant, and was formerly employed in pectoral affections; but, except as an ingredient of the compound tincture of benzoin, it has fallen into disuse. Trousseau and Pidoux recommend strongly its inhalation in *chronic laryngitis*. Either the air of the chamber may be impregnated with its vapor by placing a small portion upon some live coals, or the patient may inhale the vapor of boiling water to which the balsam has been added. It is occasionally employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); the milky liquor resulting from the addition of water to its alcoholic solution is sometimes used as a cosmetic, under the impression that it renders the skin soft. A tincture has been strongly recommended in *anal fissure*. In the East Indies, the balsam is burnt by the Hindus as a perfume in their temples of worship.

Dose, fifteen to thirty grains (1 to 2 Gm.).

BENZOL. Br.

BENZOL

(bēn'zōl)

$C_6H_6 = 77.46$

"A mixture of homologous hydrocarbons obtained from light coal-tar oil. It contains about 70 per cent. of benzene, C_6H_6 , and 20 to 30 per cent. of toluene, $C_6H_5CH_3$." Br.

Benzene, Benzole, Phenyl Hydride, Benzen; Benzene, Fr.; Phenylwasserstoff, Steinkohlenbenzol, G.; Benzolo, It.

Benzol (Benzene, U. S. P. reagent) must not be confounded with the commercial article *benzin*, which is a mixture of various hydrocarbons of light specific gravity, obtained in the distillation of petroleum. (See *Benzinum*.) Originally the two names benzol and benzin were applied to the same substance, but after the discovery of petroleum it was found that the liquid obtained by distillation from coal tar was quite different from that obtained from petroleum. In the United States it has become the custom to call the liquid obtained by the fractional distillation of petroleum having the specific gravity 0.638 to 0.660, *benzin*. It is unfortunate that in Europe, and on the Continent especially, the

term *benzin* is used for both liquids. The two substances are essentially different, although resembling each other somewhat in their solvent powers. Benzol is a definite hydrocarbon of fixed constitution, petroleum benzin a complex body of varying constitution. Benzol can be frozen; petroleum benzin has never yet been congealed. Petroleum benzin boils at from 45° to 60° C. (113° to 140° F.), while benzol boils at 79° to 80° C. Benzol can be converted into nitrobenzol, and by further treatment into aniline colors; petroleum benzin cannot. When petroleum benzin is shaken in the cold with one-third of its volume of fused crystals of absolute phenol, the latter remains undissolved, while benzol is miscible with absolute phenol in all proportions. (Allen.) According to Pusch, benzol can be distinguished from petroleum benzin by the fact that benzol forms a violet-red and petroleum benzin a raspberry-colored solution with iodine. (*A. J. P.*, xlvii. 268.) Although the term *Benzene* is given above as one of the synonyms of *Benzol*, its use abroad is gradually becoming limited to the pure hydrocarbon, C_6H_6 , while *Benzol* is applied to the mixture of benzene with its homologues *toluene*, *paraxylene*, *metaxylene*, *mesitylene*, *pseudo-cumene*, etc., as in the Br. Pharm.

Benzol was discovered by Faraday in the condensed liquid from oil gas, and was next obtained by Mitscherlich by distilling benzoic acid with lime. It was afterwards discovered by Hofmann as a constituent of coal gas tar. This tar, when distilled, furnishes *coal naphtha* or light oil of tar, a complex substance, containing a number of hydrocarbons, among which is benzol. Upon distilling this naphtha from a metallic still, surmounted by an open vessel filled with water, and containing a worm terminating in a refrigerated receiver, the benzol will pass over and condense in the receiver; while the other substances associated with it, having higher boiling points, will condense in the worm and fall back into the still. The benzol is then purified by distillation at a heat between 80° C. and 90° C. (176° F. and 194° F.), and by subjecting the product to a new distillation from one-fourth of its volume of sulphuric acid. E. Kopp purifies benzol by taking advantage of its high congealing point. He exposes the impure mixture containing it to a degree of cold sufficient to solidify it (-15° C. or 5° F.), presses the congealed mass to separate the liquid hydrocarbons, allows it to become fluid, then again freezes and presses it, and thus obtains it almost entirely pure, when it is known as "crystallizable benzene." He obtains the impure mixture containing the benzol by decomposing the heavier tar oils by a high degree of heat. (*Chem. News*, May 14, 1864, p. 229.)

Calvert of Manchester, purifies coal naphtha, so as to render it a sufficiently pure benzol to be usefully applied to the purpose of removing fatty and oily matters from animal and vegetable substances, by subjecting it to the action

of sulphuric acid, added in small quantities, so long as coloration is produced, then washing it with pure water, and afterwards subjecting it to distillation in an ordinary still. The sulphuric acid combines with the less volatile hydrocarbons present, which interfere with the solvent power of the benzol.

Prolonged treatment with sulphuric acid is also necessary to free the benzol from *thiophene*, C_4H_4S , an impurity which to the extent of about 0.6 per cent. is always present in commercial benzol. Its complete removal from the benzol is to be tested for by the *indophenin reaction* (blue coloration in presence of concentrated sulphuric acid and a small quantity of isatine). (See *Benzene*, PART III.)

In consequence of the great volatility and extreme inflammability of benzol and its attendant hydrocarbons, much care is necessary both in their preparation and in their subsequent use in order to avoid any possible exposure to flame. Very serious accidents have taken place from want of the proper caution in this respect.

Properties.—Benzol or benzene is a colorless limpid liquid, possessing an agreeable odor. Its sp. gr. is 0.85, congealing point $0^\circ C.$ ($32^\circ F.$), and boiling point $80^\circ C.$ ($176^\circ F.$). The British Pharmacopœia describes it as "a colorless volatile liquid free from opalescence, with a strong characteristic odor. Specific gravity from 0.880 to 0.888. It should begin to distil at $176^\circ F.$ ($80^\circ C.$), and about 90 per cent. of the whole should pass over at a temperature below $212^\circ F.$ ($100^\circ C.$). It should wholly distil below $248^\circ F.$ ($120^\circ C.$)."
Br. Its powers as a solvent are very extensive. Among the substances soluble in it are sulphur, phosphorus, and iodine, and most resins and fats. It dissolves quinine, but not cinchonine, with which it forms a bulky gelatinous mass. Morphine and strychnine are sparingly soluble. Its solvent power over some of the organic alkaloids led John Williams of London, to employ it in extracting them. Dragendorff has corroborated and extended this use of benzol for obtaining the alkaloids, whose salts are, however, not usually soluble in the menstruum. Benzol is also a solvent of many of the resins, of mastic, camphor, wax, fatty and oily substances, essential oils, caoutchouc, and gutta-percha. It often becomes a matter of great importance commercially to test the purity of commercial benzol, and a very thorough method of assay based on fractional distillation is proposed by A. H. Allen, in his *Commercial Organic Analysis*, 1882. The following method, originating with Schorlemmer, is based on the conversion of this hydrocarbon into aniline, and of that into one of the characteristic colors derived from it. That part of the mixture which volatilizes at $150^\circ C.$ ($302^\circ F.$) is operated on. This is treated with fuming nitric acid, which, if benzol be present, gives rise to a nitrobenzol with its bitter-almond odor. The nitrobenzol is then converted by the action of

granulated tin and hydrochloric acid into aniline, which is isolated by distilling the product with potassium hydroxide. The aniline floats on the top of the liquid that passes. A little of this gives with sodium hypochlorite a fine purple color; and a drop of it, if heated with a little corrosive sublimate, will yield the beautiful color of rosaniline. (*J. P. C.*, 4e sér., ii. 177.) According to Balls, magnesium ribbon, with the addition of a few drops of solution of platonic chloride, rapidly and completely reduces nitrobenzene in alcoholic solution to aniline, giving a solution which can be at once decanted and tested with bleaching powder. (Allen.)

Uses.—It has been asserted by Naunyn, Wiederhold, and Possolz that benzol is an active germicide; but A. Chassevant found that it has no power of destroying the vitality of spores. (*Archiv. d. Pharmacodyn.*, vol. ii., 1896.) In Chassevant's experiments it rapidly produced complete coma in the lower animals, with muscular relaxation and greatly lowered temperature ($10^\circ C.$ without death). In the early stages of the poisoning, convulsions and very rapid breathing were noticed. From one to two fluid-ounces of it are stated to have caused in man exhilaration and vertigo, followed by sleep and delirium (*J. P. C.* 1861), but it is of little value in practical medicine. In the attempt to use it as an anæsthetic, Simpson of Edinburgh, found that it caused violent constrictive headache and was scarcely capable of producing insensibility. According to Chassevant, it depresses arterial pressure by dilating the vessels, and acts most unfavorably on persons suffering from arterio-sclerosis or heart disease. According to Reynal, a mixture of ten parts of benzol, five of soap, and eighty-five of water is very destructive to parasites, and does not affect the skin or the general system. Guyot states (*B. M. J.*, 1897) that the habitual exposure to the fumes of benzol during its manufacture produces a chronic poisoning, characterized by uncertainty of gait, mental disturbance, wandering delirium, loss of sexual power, and epileptiform convulsions. According to Chassevant, *toluene* acts like *benzene*, but *xylene* is much more toxic, rapidly producing coma.

Dose, from ten minims to half a fluidrachm (0.6 to 1.8 Cc.).

BENZOSULPHINIDUM. U. S. (Br.)

BENZOSULPHINIDE SACCHARIN

(bën-zô-sûl-phī-nī'dūm)

"The anhydride of ortho-sulphamide-benzoic acid (benzoyl sulphonimide)."
U. S. "Glu-
side, or benzoyl sulphonimide, is a sweet imide

derivable from toluene. Its constitution is represented by the formula $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO} \\ \text{SO} \end{smallmatrix} > \text{NH}.$ Br.

Glusidum, Br.; Gluside, Saccharin, Neo-Saccharin; Glucosimide; Benzoyl-Sulphonicimide, $\text{C}_6\text{H}_5\text{COSO}_2\text{N}$; H; Anhydro-orthosulphamidebenzoic Acid; Glukugin; Acide Anhydro-orthosulfamide-benzoïque, *Fr. Cod.*; Sulfimide-benzoïque, Sucre de Houllie, *Fr.*; Benzoesauresulfimid, Syucose, Saccharol, Toluolsüss, Zuckerin, G.; Sacarina, *Sp.*

Preparation.—This artificial sweetening substance, which is known commonly as "saccharin," is made from toluene by first forming the ortho-sulphonic acid $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{SO}_3\text{H} \\ \text{CH}_3 \end{smallmatrix}$; from this the sulphamide $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{SO}_2\text{NH}_2 \\ \text{CH}_3 \end{smallmatrix}$; from this, by oxidation, the sulphamide-benzoic acid $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{SO}_2\text{NH}_2 \\ \text{COOH} \end{smallmatrix}$, of which the anhydride is the official compound. When dissolved in alkaline hydroxide solutions the salt of the sulphamide-benzoic acid is formed as $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{SO}_2\text{NH}_2 \\ \text{COONa} \end{smallmatrix}$. (The reader is referred to *Soluble Saccharin, PART II.*)

Properties.—A white powder, melting at 200°C . with partial decomposition, evolving the odor of bitter almonds. It is soluble in water, from which it can be crystallized; also in alcohol, ether, glycerin, and glucose. Its taste in diluted solutions is intensely sweet, so that 1 part of saccharin will sweeten quite strongly 10,000 parts of water. Saccharin may be detected in sugar solutions by extracting with ether, evaporating, and fusing the residue, which, if saccharin, will melt at about 220°C ., and fused with potassium nitrate and sodium carbonate will show sulphuric acid. The weight of BaSO_4 obtained in this way from 100 Gm. of sugar multiplied by 0.785 will give the weight of saccharin extracted.

The aqueous solution of saccharin has a distinctly acid reaction and forms salts. Its most remarkable property is its sweet taste, which is said to be three hundred times more intense than that of sugar. The commercial product, according to Pope, frequently contains para-sulphamide-benzoic acid, from which impurity it can be freed by recrystallization, acetone being used as the solvent. Hefelman has furnished a process for assaying saccharin. (See *Proc. A. Ph. A.*, 1895, 701.) The difference in melting points of pure saccharin and para-sulphamide-benzoic acid is also used for distinguishing them; the former melts at 220°C . and the latter at 286.5°C . (*Ph. Cb.*, 1896, 279.)

Saccharin is officially described as "a white crystalline powder, nearly odorless, having an intensely sweet taste even in dilute solutions. Soluble in 250 parts of water, and in 25 parts of alcohol, and but slightly soluble in ether or chloroform at 25°C . (77°F .); soluble in 24 parts of water at 100°C . (212°F .). It is easily soluble in ammonia water, in alkali hy-

droxide solutions, and in a solution of sodium bicarbonate, with the evolution of carbon dioxide. Heated between 219° and 220°C . (426.2° and 428°F .) it melts, and at higher temperatures burns with an odor of oil of bitter almond, without leaving a weighable residue (absence of *inorganic impurities*). If 0.2 Gm. of Benzosulphinide be dissolved with agitation in 10 Cc. of pure sulphuric acid, and the solution kept at a temperature of from 48° to 50°C . (118.4° to 122°F .), on a water-bath, it should not, within ten minutes, show a brown color (absence of *carbohydrates*). If 0.2 Gm. of Benzosulphinide be dissolved in 5 Cc. of potassium hydroxide T.S., the solution should be clear, and not become colored, even on prolonged heating (absence of *glucose*). A similar solution mixed with 5 Cc. of alkaline cupric tartrate V.S. should not, on heating, deposit any red cuprous oxide (absence of *glucose* or *milk-sugar*). If to a hot aqueous solution of Benzosulphinide, ferric chloride T.S. be added, drop by drop, no precipitation or violet color should appear (absence of *benzoic* or *salicylic acids*)." *U. S.*

The British Pharmacopœia furnishes the following characters and tests: "A light, white, minutely crystalline powder, having an intensely sweet taste in dilute solutions. When heated it fuses, and then sublimes with partial decomposition. It is soluble in 400 parts of cold water, in 24 parts of boiling water, in 25 parts of alcohol (90 per cent.), and but slightly in ether or chloroform. It is very soluble in diluted solution of ammonia; also in solution of sodium bicarbonate, with evolution of carbonic anhydride. A warm solution of sodium bicarbonate, when neutralized with Gluside and evaporated to dryness, yields 'soluble gluside' or 'soluble saccharin,' which is very soluble in water, 100 parts of Gluside yielding nearly 113 parts of neutral 'soluble gluside.' Neither Gluside nor soluble gluside is blackened by sulphuric acid, even when the mixture is gently warmed for a short time (absence of sugar, etc.). On evaporating either variety with excess of solution of potassium hydroxide, maintaining the residue in a state of semi-fusion for a few minutes, cooling, dissolving in water, faintly acidulating with hydrochloric acid, and adding a few drops of test-solution of ferric chloride, a reddish-brown or purplish color is produced. A solution of 0.5 gramme of Gluside in 80 cubic centimetres of warm water, set aside for 12 hours, deposits tabular crystals which melt between 426°F . and 428°F . (218.8°C . and 220°C .); and it should not, even when briskly shaken, deposit crystals melting at a higher temperature (absence of sulphamido-benzoic acid)." *Br.*

Uses.—Taken internally, saccharin is rapidly absorbed and eliminated unchanged through the kidneys. It is almost free from general physiological activities, Mosso and Aducco having given 75 grains to a man without sensible effect. It is a very feeble antiseptic but appears to

have no action upon gastric digestion. On account of its lack of active properties and its sweet taste it affords a valuable substitute for sugar in *diabetes*, *obesity*, and other diseases in which that food is contra-indicated. Saccharin may either be administered in the form of solution in glycerin, or its salt may be employed.

Dose, three to five grains (0.2 to 0.32 Gm.).

BERBERIS. U. S.

BERBERIS [*Berberis Aquifolium*, Oregon Grape Root]
(bēr'be-ris)

"The rhizome and roots of *Berberis Aquifolium* Pursh, and other species of *Berberis* (Fam. *Berberidaceæ*)." U. S.

Rocky Mountain Grape; California Barberry; Holly-leaf Barberry.

The *Oregon grape* is a tall shrub, about 6 to 7 feet high, with evergreen, coriaceous, bright and shining leaves, and having numerous small, yellowish-green flowers in the early Spring, and later clusters of purple berries containing an acid pulp. It is a native of the mountain-states on both the east and west sides of the Rockies. (See *Berberis*, PART II.) For a description of the bark of *B. aristata*, D. C. (*Nepaul barberry*), by Hartwick, see *Ph. Rev.*, 1896, 232.

The root of berberis occurs in pieces about a foot long, one-fourth of an inch thick, of a brownish exterior, but yellowish within, yielding a bright lemon-colored bitter powder. It is officially described as "in more or less knotty, irregular pieces of varying length and from 3 to 20 Mm. in diameter; bark from $\frac{1}{2}$ to 2 Mm. thick; wood yellowish, distinctly radiate with narrow medullary rays, hard and tough; rhizome with a small pith; odor distinct; taste strongly bitter. Pieces without the bark should be rejected." U. S.

Berberis contains the alkaloids *berberine*, $C_{20}H_{17}NO_4$; *oxyacanthine*, $C_{18}H_{15}NO_3$; and *berbamine*, $C_{18}H_{15}NO_3$, together with phytosterin, gum, fat, resin and wax. Berberine and oxyacanthine were isolated by H. B. Parsons (*N. R.*, 1882, 83), the percentage of the former is said to be 2.35 and of the latter 2.82. Jungk and Stubbe investigated the alkaloids from berberis, and found that the three alkaloids in *B. Aquifolium* are identical with those found in *B. vulgaris*. Rüdel examined and described these alkaloids (*J. C. S.*, 1892, 641). Gordin and Merrell (*Proc. A. Ph. A.*, 1901, 228), objected to the method of Gaze (*Chem. Ch.*, 1890, 590) for making berberine from acetone-berberine (see *Hydrastis*).

Uses.—Both the berries and the roots of the *Berberis Aquifolium* have been strongly recommended by various clinicians as alterative, laxative, tonic, and diuretic; very useful in chronic *syphilitic* and *scrofulous cachexias*, in *chronic skin diseases*, especially of the scaly type, in the convalescence from *malarial* and other *fevers*, and in *chronic uterine disease*. By

some they are believed to have a distinct action upon the liver, and to be valuable in *chronic hepatitis*.

Dose, twenty to thirty grains (1.3 to 2 Gm.), of the fluidextract, ten to thirty minims (0.6 to 1.8 Cc.).

Off. Prep.—Fluidextractum Berberidis, U. S.

BETANAPHTHOL. U. S. (Br.)

BETANAPHTHOL [Naphtol, Pharm. 1890, Naphthol]

(bē-tā-nāph'thōl)

$C_{10}H_7OH = 142.98$

"A monatomic phenol occurring in coal-tar, but usually prepared from naphthalene. Betanaphthol should be kept in dark amber-colored, well-stoppered bottles." U. S. "Beta-naphthol, or beta-mono-hydroxy-naphthalene, $C_{10}H_7OH$, is usually prepared from naphthalene-sulphonic acid." Br.

Naphthol, Br.; β -Naphthol, Beta-mono-hydroxy-naphthalene, Iso-naphthol; Naphtol β , Fr. *Cod.*; Naphtholum, P. G.; Beta-Naphtholum, G.; Nafтол β , It.

Preparation.—On digesting four parts of naphthalene with three parts of sulphuric acid at 80° C. there is formed α - and β -naphthalene sulphonic acids, $C_{10}H_7SO_3H$, which may be separated by means of the barium or lead salts. When heated with sulphuric acid, the α acid passes into the β variety; therefore the latter acid is exclusively produced at higher temperatures (160° C.). Both of the naphthalene sulphonic acids, when fused with alkaline hydroxides, yield the corresponding naphthols, which are designated as α - and β -naphthol, respectively. The second of these, beta naphthol, is the official naphthol, $C_{10}H_7OH$. It bears to naphthalene the same relation that phenol does to benzene. It is officially described as in "colorless or pale buff-colored, shining crystalline laminae or a white or yellowish-white crystalline powder, having a faint phenol-like odor and a sharp and pungent but not persistent taste. Permanent in the air. Soluble in about 950 parts of water, and in 0.61 part of alcohol at 25° C. (77° F.); in about 75 parts of boiling water, and very soluble in boiling alcohol; easily soluble in ether, chloroform, or solutions of alkali hydroxides. Betanaphthol melts at 122° C. (251.6° F.) and boils at 286° C. (546.8° F.). It sublimes readily when heated; when in alcoholic or aqueous solution, it is volatilized with the vapor of alcohol or water. On ignition it leaves no residue. It is neutral to litmus paper which has been moistened with alcohol. A cold saturated aqueous solution of Betanaphthol when mixed with ammonia water exhibits a faint bluish fluorescence. On adding about 0.1 Gm. of Betanaphthol to about 5 Cc. of an aqueous solution of potassium hydroxide (1 in 4), then about 1 Cc. of chloroform, and gently warming the mixture, the aqueous layer will acquire a blue tint, changing afterwards to green and brown. Ferric chloride T.S. colors an aqueous solution greenish, and after some

time causes the separation of white flakes, which turn brown upon the application of heat. Betanaphthol should dissolve in 50 parts of ammonia water without leaving a residue (absence of *naphthalene*), and the solution should not have a deeper color than pale yellow (absence of *other organic impurities*). An aqueous solution of Betanaphthol on the addition of chlorinated lime should show a pale yellow color and not a dark violet (distinction from, and absence of, *alphanaphthol*). An aqueous solution of Betanaphthol on the addition of a few drops of iodine T.S., followed by sodium hydroxide T.S. in excess, should show no color (distinction from, and absence of, *alphanaphthol*, which produces an intensely violet color.)" *U. S.*

The British Pharmacopœia describes it as "in white or nearly white crystalline laminae, or in powder. It has a sharp, pungent taste, and an odor resembling phenol. Soluble in about 1000 parts of cold water, in 75 parts of boiling water, in less than 2 parts of cold alcohol (90 per cent.), and very soluble in boiling alcohol (90 per cent.), ether, chloroform or solution of sodium hydroxide. Melting point 251.6° F. (122° C.). On the addition of 1 drop of solution of ammonia to a hot saturated aqueous solution of Beta-naphthol a blue fluorescence is developed. A cold saturated aqueous solution gives a white turbidity with solution of chlorine, which, on the addition of excess of solution of ammonia, gives place to a green or brown coloration. 0.1 gramme of Beta-naphthol dissolved in 10 cubic centimetres of boiling water, and treated with 10 drops of a 3 per cent. aqueous solution of ferric chloride, gives a white precipitate becoming brown, but not violet (absence of *alphanaphthol*). Beta-naphthol should be neutral to *litmus paper* moistened with alcohol (90 per cent.), and should leave no residue on heating to redness (absence of mineral impurities)." *Br.* For Yvon's tests to distinguish between alpha and betanaphthol, see *Proc. A. Ph. A.*, 1892, 955; see also *Chem. News*, 1892, 18. For Liebman's test for the presence of alphanaphthol, see *M. R.*, 1897, 281.¹

¹ *Alphanaphthol*.—According to Maximovitch, *alphanaphthol* has the same action upon pathogenetic germs and upon the higher animals as has *betanaphthol*, having the superiority over the other compound, however, of being less poisonous to the higher animals in proportion to its germicidal power. It may be used in the same strength of solution and the same dose as *Betanaphthol*. *Alphanaphthol* has been proposed as a test for sugar in urine. Posner and Epenstein have studied the action of the test, and considered it to be free from many of the objections raised against other tests for sugar. The test depends upon the fact that a solution of sugar, in the presence of pure concentrated sulphuric acid and a solution of *alphanaphthol*, gives a violet-colored reaction, due, according to Udransky, to the separation of furfural. This reaction occurs not only with sugars, but with all carbohydrates and with certain albuminoids; hence the urine must be free from albumin. The test is said to be extremely sensitive, showing one-hundredth of one per cent. of sugar. The urine must always be previously diluted. Winkler's test for hydrochloric acid in the stomach is performed as follows: 5 Gm. of *alphanaphthol* are dissolved in 100 Cc. of alcohol, to which is added from 0.5 to 1.0 Gm. of grape sugar. A mixture of the filtered gastric

Uses.—It was claimed by Bouchard and Maximovitch for *betanaphthol*, that it is an active germicide, practically non-toxic to the human being. More recent researches seem, however, to show that while it is extraordinarily free from poisonous effects upon the higher animals, its influence on pathogenetic germs is also feeble. In internal medicine it has been used—in *dilatation of the stomach* and in *intestinal diseases* of all kinds—for the purpose of checking fermentative changes in the alimentary canal, and has maintained itself as one of the best of this unsatisfactory class of remedies. In *typhoid fever* it is alleged to be especially serviceable. Externally, it has been used dissolved in oil or alcohol by Kaposi and later dermatologists in the treatment of *eczema*, *ichthyosis*, *favus*, and other skin diseases. Its solution has also been employed largely by surgeons for the washing out of pathological cavities. The employment of it intravenously or by the mouth, for the purpose of destroying germs in the blood in zymotic diseases, has established its non-utility in these affections. Large doses of it are likely to disturb the stomach. The following formulas may be used in making the solutions: 1. *Weak solution*, for parts in which mucous membranes are exposed: β -naphthol, 5 grammes; alcohol at 60° F., 1 liter. 2. *Ordinary solution*: β -naphthol, 15 grammes; alcohol at 60° F., 1 liter. 3. *Strong solution*, for touching diseased portions of the skin, or septic excoriations: β -naphthol, 15 to 500 grammes per liter. 4. *Solution for interstitial injections, or closed septic cavities*: β -naphthol, 5 grammes; alcohol at 90° F., 33 grammes; hot distilled water, to make 100 cubic centimeters; filter, and use warm. A few drops may be injected into indurated glands or abscesses.

Dose, two to five grains (0.13 to 0.32 Gm.) best administered in capsule.

BISMUTHI CITRAS. U. S.

BISMUTH CITRATE

(biş-mū'thi cī'trās)

$\text{BiC}_6\text{H}_5\text{O}_7 = 394.52$

"Bismuth Citrate should yield not less than 58 percent., nor more than 60 percent., of pure bismuth oxide." *U. S.*

Citrate of Bismuth; Bismuthum Citricum; Citrate de Bismuth, *Fr.*; Citronensaures Wismuth, Wismut-citrat, Citronensaures Wismutoxyd, *G.*

juice is then evaporated with a few drops of the reagent in a porcelain dish on a water bath; if free hydrochloric acid be present, a bluish-violet marginal zone will appear and rapidly become inky black. Various compounds of naphthol have been proposed in medicine. The substance recommended by Pollalion, under the name of *microcidin*, as being ten times more powerful than phenol and less toxic than *betanaphthol*, is said to be *sodium naphthol*. (*Helbing's Med. Mat. Med.*, 79.)

Betol (or β -naphthyl salicylate) is specially treated under PART II.

Benzonaphthol; or β -naphthyl benzoate, is a compound of benzoyl and β -naphthol, which in the intestinal tract, theoretically at least, is split up into these constituents. It has been given in doses of from ten or fifteen grains up to ninety grains a day. (See *Benzonaphthol*, PART II.)

* "Bismuth Subnitrate, *one hundred grammes* [or 3 ounces av., 231 grains]; Citric Acid, *seventy-five grammes* [or 2 ounces av., 282 grains]; Distilled Water, *a sufficient quantity*. Mix the Bismuth Subnitrate and the Citric Acid with *four hundred cubic centimeters* [or 13½ fluidounces] of Distilled Water, and heat on a bath of boiling water, with frequent stirring, until a drop of the mixture yields a clear solution with ammonia water. Then add *five thousand cubic centimeters* [about 11 pints] of Distilled Water, allow the suspended matter to deposit, wash the precipitate, first by decantation, and afterwards on a strainer, with Distilled Water, until the washings are tasteless, and dry the residue at a gentle heat." U. S.

As citric acid ($\text{H}_3\text{C}_6\text{H}_5\text{O}_7$) is tribasic, one atom of bismuth, being trivalent, will exactly replace the three hydrogen atoms of the citric acid and form a neutral bismuth citrate. When bismuth subnitrate is boiled with a solution of citric acid it is decomposed, the nitric acid is replaced by the citric acid, and the insoluble bismuth citrate is formed; the completion of the process is known by the mixture yielding a clear solution with ammonia water.

Properties.—It is officially described as "a white, amorphous or micro-crystalline powder, odorless and tasteless, and permanent in the air. Insoluble in water or alcohol, but soluble in ammonia water, and in solutions of alkali citrates. When strongly heated the salt chars, and, on ignition, leaves a more or less blackened residue having a yellow surface, and soluble in warm nitric acid; this solution, when dropped into a large excess of water, occasions a white turbidity. A solution of 1 Gm. of Bismuth Citrate in ammonia water, when treated with hydrogen sulphide in excess, yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it boiled with an excess of lime water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric acid, and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (limit of nitrate). Three Gm. of Bismuth Citrate, after ignition, should not respond to Bettendorf's Test for arsenic (see Part III, Test No. 16). If 3 Gm. of the salt be ignited, the residue dissolved in just a sufficient quantity of warm nitric acid, and the solution poured into 100 Cc. of water, a white precipitate is produced. If the filtrate separated from this precipitate be evaporated on a water-bath to 30 Cc., the liquid again filtered, and the new filtrate divided into portions of 5 Cc. each, these should respond to the tests for purity described under *Bismuthi Subcarbonas* (absence of lead, copper, silver, chlorides, and sulphates). If 1 Gm. of Bismuth Citrate be thoroughly ignited in a porcelain crucible, and, after cooling, 5 Cc. of nitric acid be added to the residue, drop by drop, warming until complete solution is

effected, then evaporating to dryness, and again igniting, a residue of bismuth oxide should be left weighing not less than 0.58 Gm. nor more than 0.6 Gm." U. S.

Uses.—This salt is employed solely for pharmaceutical purposes.

Off. Prep.—Bismuthi et Ammonii Citras, U. S.

BISMUTHI ET AMMONII CITRAS.

U. S.

BISMUTH AND AMMONIUM CITRATE

[Bismuth Ammonio-Citrate]

(biš-mū'thī ēt am-mō'nī-i cī'trās)

"Bismuth and Ammonium Citrate should yield not less than 48 percent. of pure bismuth oxide." U. S.

Bismuthi Ammonio-citras; Bismuthum Citricum Ammoniatum; Citrate of Bismuth and Ammonium; Citrate de Bismuth et d'Ammoniaque, Fr.; Citronensaures Wismutoxyd-Ammonium; Wismutammoncitrat, Citronensaures Wismutammonium, G.

* "Bismuth Citrate, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity*. Mix the Bismuth Citrate with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Distilled Water and rub it to a smooth paste, heat the mixture on a water-bath, and gradually add Ammonia Water until the salt is dissolved and the liquid is neutral or has only a faintly alkaline reaction. Then filter the solution, evaporate it on a water-bath to a syrupy consistence, and spread it upon plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in amber-colored, well-stoppered bottles, protected from light." U. S.

The British Pharmacopœia (1898) does not recognize this salt, which has been used quite extensively during the last twenty years, principally for preparing extemporaneously the London Liquor Bismuthi originally suggested by Schacht. (See *Liquor Bismuthi et Ammonia Citratis*.)

Properties.—The U. S. Pharmacopœia (8th Rev.) describes it as in "shining, pearly or translucent scales, odorless, having a metallic taste, and becoming opaque with loss of ammonia on exposure to the air. Very soluble in water, and sparingly soluble in alcohol. When strongly heated the salt fuses, and finally leaves a blackened residue, having a yellow surface, and soluble in warm nitric acid. The acid solution, when dropped into a large excess of water, occasions a white turbidity. The aqueous solution of the salt is neutral or faintly alkaline to litmus paper. When boiled with a slight excess of sodium hydroxide T.S. it evolves ammonia, and its aqueous solution, when treated with hydrogen sulphide, yields a black precipitate. If the filtrate from the latter be deprived by heat of the excess of hydrogen sulphide and cooled, a portion of it, boiled with an excess of lime water, yields a white precipitate. If another portion of the cooled filtrate be mixed with an equal volume of concentrated sulphuric

acid (free from nitrous compounds) and again cooled, no brown or brownish-black color should appear around a crystal of ferrous sulphate dropped into the liquid (absence of *nitrate*). If 3 Gm. of the salt be ignited and the residue dissolved in just a sufficient quantity of warm nitric acid, and the solution poured into 100 Cc. of water, a white precipitate is produced. If the filtrate separated from this precipitate be evaporated on a water-bath to 30 Cc., the liquid again filtered, and the new filtrate divided into portions of 5 Cc. each, these should respond to the tests for purity described under *Bismuthi Subcarbonas*. Three Gm. of Bismuth and Ammonium Citrate, after ignition, should not respond to Bettendorf's Test for *arsenic* (see PART III, Test No. 16). If 1 Gm. of Bismuth and Ammonium Citrate be thoroughly ignited in a porcelain crucible, and if, after cooling, 5 Cc. of nitric acid be added to the residue, drop by drop, warmed until complete solution is effected, then evaporated to dryness, and again ignited, the residue of bismuth oxide should weigh not less than 0.48 Gm." *U. S.* As frequently seen in commerce it is not entirely soluble in water; this is due to the loss of ammonia through exposure, and a few drops of ammonia water added to the turbid solution are generally sufficient to restore its transparency. The Committee of Revision very properly omitted to give its chemical formula, as it is by no means proved that it has a definite composition. It is believed by some to be a true double citrate, $\text{BiC}_6\text{H}_5\text{O}_7(\text{NH}_4)_3\text{C}_6\text{H}_5\text{O}_7$. On the other hand, Bartlett (*Zeit. An. Chem.*, 1865, p. 305) obtained on evaporation of the ammoniacal solution $\text{BiC}_6\text{H}_5\text{O}_7\text{NH}_3 + 3\text{H}_2\text{O}$, and Rother (*Jahresb.*, 1876, p. 564) obtained on crystallizing from warm ammonia $\text{BiC}_6\text{H}_5\text{O}_7 \cdot 3\text{NH}_3 + 3\text{H}_2\text{O}$. "Ten grains dissolved in water, and treated with sulphuretted hydrogen in excess, yield a precipitate which, when washed and dried, weighs about six and a half grains." *Br.* (1885).

Uses.—This salt differs from the older preparations of bismuth in its solubility, and probably is for this reason more rapid, more astringent, and more irritant in its action. In cases of irritation or inflammation of the *gastro-intestinal mucous membrane* it is very much inferior to the insoluble preparations, but when there is relaxation with excessive discharges it may usefully be employed.

Dose, one to three grains (0.065 to 0.20 Gm.).

BISMUTHI OXIDUM. Br.

BISMUTH OXIDE

(bīs-mū'thī ōx'ī-dūm)

$\text{Bi}_2\text{O}_3 = 461.44$

"Bismuth Oxide, Bi_2O_3 , may be prepared by boiling bismuth oxynitrate with solution of sodium hydroxide." *Br.*

Bismuth Trioxide; Bismuthum Oxydatum, Oxydum Bismuthicum; Oxyde de Bismuth, *Fr.*; Wismutoxyd, *G.*

Bismuth subnitrate is decomposed by solution of sodium hydroxide in this process, bismuth hydroxide being formed, which is precipitated, while sodium nitrate remains in solution.

At the temperature of 100°C. (212°F.) the bismuth hydroxide is decomposed, water is liberated, and the anhydrous oxide is left.

Properties.—Bismuth oxide is a powder of a dull lemon-yellow color, insoluble in water, but soluble without effervescence in nitric acid, mixed with half its volume of water. The British Pharmacopœia 1898 describes it as "a slightly brownish-yellow powder. It should answer to the general characters and tests enumerated under 'Bismuth Oxycarbonate.' Each gramme should yield 1.1 grammes of bismuth sulphide. Heated to incipient redness it is scarcely diminished in weight (absence of bismuth oxycarbonate, bismuth oxynitrate, and moisture)." *Br.*

Uses.—Bismuth oxide resembles bismuth subnitrate in its medicinal properties, and may be administered in similar doses.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

BISMUTHI SUBCARBONAS. U. S. (Br.)

BISMUTH SUBCARBONATE

(bīs-mū'thī sūb-cār'bō-nās)

"Bismuth Subcarbonate should yield not less than 90 percent. of pure bismuth oxide." *U. S.* "Bismuth Oxycarbonate, $(\text{Bi}_2\text{O}_2\text{CO}_3)_2 \cdot \text{H}_2\text{O}$, may be prepared by the interaction of bismuth nitrate and ammonium carbonate." *Br.*

Bismuthi Carbonas, Br. Carbonate of Bismuth, Oxycarbonate of Bismuth, Bismuthyl carbonate; Bismuthum Subcarbonicum, Subcarbonas Bismuthicus; Souscarbonate de Bismuth, *Fr.*; Basisches Kohlen-saures Wismutoxyd, Wismutsulcarbonat, *G.*

A process for this salt is no longer official; that of the U. S. P. 1870 is given below.¹

¹ "Take of Bismuth, in pieces, two troyounces; Nitric Acid eight troyounces and a half; Water of Ammonia five fluidounces; Carbonate of Sodium ten troyounces; Distilled Water a sufficient quantity. Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. To the filtered liquid, previously diluted with an equal measure of Distilled Water, slowly add the Water of Ammonia, constantly stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with two pints of Distilled Water, and drain it again. Then place the precipitate in a proper vessel, add the remainder of the Nitric Acid, and afterwards four fluidounces of Distilled Water, and set the solution aside. At the end of twenty-four hours, filter through paper. Dissolve the Carbonate of Sodium in twelve fluidounces of Distilled Water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless. Lastly, press, dry it on bibulous paper with a gentle heat, and rub it into powder." *U. S.* 1870.

This preparation was first made official in the 1860 edition of the U. S. Pharmacopœia. As metallic bismuth generally contains arsenic, it is very important to provide that this should be left behind, in the processes for making its medicinal preparations. It is on this account that the formula of the U. S. P. 1870 was so elaborate. The bismuth is first dissolved in nitric acid, a portion of which oxidizes the metal, with the evolution of nitrous vapors, while another portion combines with the oxide produced to form bismuth nitrate. At the same time the arsenic is also oxidized at the expense of the nitric acid, and unites with a portion of the oxidized metal so as to produce bismuth arsenate. Both of these salts, therefore, are contained in the solution, which is very concentrated. Both have the property, when their solution is diluted with water, of separating into two salts, one an insoluble subsalt which is deposited, and the other a soluble acid salt which is held in solution. But the arsenate is more disposed to the change than the nitrate, and requires for the purpose a smaller amount of water of dilution. Hence the first direction, after the metal has been dissolved, is to add a moderate quantity of distilled water, insufficient to cause the decomposition of the nitrate. From this diluted solution the insoluble subarsenate is slowly deposited, so as, in the course of twenty-four hours, to free it almost if not entirely from the poisonous metal. This is separated by filtration, and the solution is now diluted with a much larger quantity of distilled water, which causes a copious deposition of bismuth subnitrate. But, in order not to waste the acid nitrate remaining in solution, this is decomposed by ammonia, which takes most of the nitric acid, and precipitates the bismuth combined with the remainder, in the form of subnitrate. The whole of the precipitated subnitrate, thus freed from arsenic, is redissolved in nitric acid, and the solution of the nitrate now obtained, being diluted with just so much water as to produce a commencing precipitation of subnitrate, is freed by filtering from the small quantity formed, and slowly added to a solution of sodium carbonate. An interchange takes place; sodium nitrate and bismuth carbonate are formed, the former of which remains in solution, and the latter is deposited. This part of the process tends still further to get rid of the arsenic, for if any of the arsenic acid or bismuth arsenate existed in the solution the poisonous acid would combine with the soda, and, thus forming a soluble salt, would be retained by the water. Nothing now remains but to wash, dry, and powder the precipitate.

The British (1885) process (see U. S. D., 17th ed., p. 265) is more simple, because, using bismuth already purified, it is without the preliminary measures taken in the U. S. process to separate the arsenic.

Properties.—Bismuth subcarbonate is “a white or pale yellowish-white powder, of somewhat varying chemical composition, odorless and

tasteless, and permanent in the air. Insoluble in water or alcohol, but completely soluble in nitric or hydrochloric acid, with copious effervescence. When heated to redness the salt loses water and carbon dioxide, and should leave not less than 90 percent. of a yellow residue, which is soluble in nitric or hydrochloric acid and blackened by hydrogen sulphide T.S.” U. S. Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9.5 per cent. of its weight (U. S. 1870) in consequence of the escape of carbon dioxide, and is converted into the anhydrous trioxide, of a light yellow color. When mixed with sulphuric acid, and subjected to Marsh’s test, it should yield no arsenic, or merely a trace.

Tests.—“If a solution of 0.3 Gm. of the salt in 10 Cc. of diluted nitric acid be treated with 0.1 Cc. of tenth-normal silver nitrate V.S., and the precipitate, if any, removed by filtration, the clear filtrate should remain unaffected by the further addition of the reagent (limit of *chlorides*). If 3 Gm. of the salt be dissolved in just a sufficient quantity (about 4 Cc.) of warm nitric acid, and the solution poured into 100 Cc. of water, a white precipitate is produced. After filtering, and evaporating the filtrate on a water-bath to 30 Cc., again filtering, and dividing this filtrate into portions of 5 Cc. each, these should respond to the following tests: On mixing one portion with an equal volume of diluted sulphuric acid, it should not become cloudy (absence of *lead*). If another portion be precipitated with a slight excess of ammonia water, the supernatant liquid should not exhibit a bluish tint (absence of *copper*). Other portions should not be affected by barium nitrate T.S. (*sulphate*), nor yield with hydrochloric acid a precipitate which is insoluble in a slight excess of the latter (*silver*). If 1 Gm. of the salt be boiled with 10 Cc. of a mixture of equal parts of acetic acid and water, the solution cooled and filtered, and the filtrate freed from bismuth by hydrogen sulphide, boiled, and again filtered, the last filtrate should leave no residue on evaporation (absence of *alkalies* and *alkali earths*). On boiling 1 Gm. of the salt with 10 Cc. of potassium hydroxide T.S., it should not evolve the odor of ammonia. If 0.05 Gm. of Bismuth Subcarbonate be agitated with 5 Cc. of a mixture of equal parts of water and ferrous sulphate T.S., and then cautiously poured over 5 Cc. of sulphuric acid (free from nitrous compounds), so as to form a layer above, no brownish-red zone should form at the line of contact of the two liquids (limit of *subnitrate*). Two Gm. of Bismuth Subcarbonate should not respond to Bettendorf’s Test for *arsenic* (see PART III, Test No. 16). If 1 Gm. of Bismuth Subcarbonate be thoroughly ignited at red heat in a porcelain crucible, the residue of bismuth oxide should weigh not less than 0.9 Gm.” U. S. The British Pharmacopœia describes it as follows: “A whitish powder, the general chemical characters and reactions of which are similar to those of Bis-

muth Oxide and Bismuth Oxynitrate. All three compounds are heavy powders insoluble in water, but soluble in nitric acid diluted with half its bulk of water. Each yields the reactions characteristic of bismuth. When either is dissolved in a little hydrochloric acid, the solution diluted with water slightly acidulated with the same acid, and then excess of hydrogen sulphide passed through the liquid, a brownish-black precipitate of bismuth sulphide falls. This precipitate, when rapidly washed on a counterpoised filter with water, and quickly dried at 212° F. (100° C.), serves for the estimation of the amount of bismuth present in the compound. These bismuth salts, when suitably treated, should yield no characteristic reaction with the tests for silver, lead, copper, arsenium, iron, zinc, calcium, magnesium, chlorides, or sulphates, nor with the tests for selenium or tellurium. Bismuth Oxycarbonate affords the reactions characteristic of carbonates, but not more than the slightest reactions with the tests for nitrates. Each gramme of it should yield 0.99 gramme of bismuth sulphide when treated as described above." *Br.*

Uses.—This salt was brought into notice by Hannon of Brussels (*Ann. Thér.*, 1857, 214), on the ground that it was more tonic than the subnitrate; it is, however, exactly equivalent to the latter salt in therapeutic action.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

Off. Prep.—Trochiscus Bismuthi Compositus, *Br.*

BISMUTHI SUBGALLAS. U. S.

BISMUTH SUBGALLATE

(bis-mū'thi sūb-gāl'lās)

"Bismuth Subgallate should yield not less than 52 percent., nor more than 57 percent., of pure bismuth oxide." *U. S.*

Dermatol; Bismuthyl Gallate; Gallate Basique de Bismuth, *Fr. Cod.*; Sousgallate de Bismuth, *Fr.*; Bismutum subgallicum, *P. G.*; Basisches Wismutgallat, *G.*; Gallato basico de bismuto, *Sp.*

Preparation.—Bismuth Subgallate was originally prepared by Bley in 1841; Fischer again prepared and described it in 1891. It was introduced to the medical profession under the proprietary name of "Dermatol," but as it was found to be bismuth monogallate, it is now known under its chemical name. Its composition has been stated to be $\text{C}_6\text{H}_2(\text{OH})_3\text{COOBi}(\text{O})_2$. F. T. Greene proposes the following process. Normal bismuth nitrate, 1 oz. av.; glacial acetic acid, 2 fl. oz. or q. s.; gallic acid, 250 grains. Dissolve the normal bismuth nitrate in the glacial acetic acid; add a pint of water. If bismuth salts should precipitate, add more glacial acetic acid until clear. Filter off impurities. Dissolve the gallic acid in a pint of warm water; mix the solutions; allow the precipitate to subside; decant; wash by decantation with warm water until washings no longer show acid reaction. Dry at 100° C.; rub to powder. See *Ph. Rund.*, 1896, 85; *Ph. Ztg.*, 1901, 1033.

Properties.—It is officially described as "an amorphous, bright yellow powder, somewhat variable in chemical composition, without odor or taste, and permanent in the air. Insoluble in water, alcohol, and ether; readily soluble with decomposition in hydrochloric, nitric, and sulphuric acids, if these be heated; insoluble in very dilute mineral acids; readily soluble in solutions of the alkali hydroxides, forming a clear yellow-colored solution, which rapidly changes to a deep red. When heated to 120° C. (248° F.) the salt loses from 5 to 7 percent. of water, and on subsequent heating to redness it at first chars, finally leaving a yellow residue, which is soluble in hydrochloric and nitric acids and is blackened by ammonium sulphide T.S. Upon thoroughly agitating 0.1 Gm. of Bismuth Subgallate with an excess of hydrogen sulphide T.S., a black precipitate results; upon filtering and then boiling the filtrate to remove the dissolved gas, the cold filtrate, after the addition of 1 drop of ferric chloride T.S., will assume a blue-black coloration. If 0.5 Gm. of the salt be well shaken with 5 Cc. of alcohol and filtered at once, the filtrate should not turn moistened blue litmus paper red (absence of free gallic acid). If 0.5 Gm. of Bismuth Subgallate be well mixed with 5 Cc. of diluted sulphuric acid, 5 Cc. of ferrous sulphate T.S. added, and this mixture cautiously poured, without shaking, over 5 Cc. of sulphuric acid (free from nitrous compounds) contained in a test-tube, no brown ring should form after standing for ten minutes (limit of nitrate). If 3 Gm. of Bismuth Subgallate be ignited in a porcelain crucible, and, after cooling, nitric acid be cautiously added to the residue drop by drop, warming until it is dissolved, then evaporating to dryness and again igniting and cooling, the residue, after cautiously dissolving in nitric acid by the aid of gentle heat, should, after concentrating to about 4 Cc., be poured into 100 Cc. of water, and after filtering and evaporating the filtrate on a water-bath to 30 Cc., again filtering, and dividing this filtrate into portions of 5 Cc., then each of these should respond to the tests for purity described under *Bismuthi Subcarbonas*. The residue resulting from the ignition and subsequent treatment of 2 Gm. of the salt, as described below, should not respond to Bettendorff's Test for arsenic (see PART III, Test No. 16). If 1 Gm. of Bismuth Subgallate be thoroughly ignited in a porcelain crucible, and, after cooling, 5 Cc. of nitric acid be added to the residue, drop by drop, warming until complete solution has been effected, this, upon evaporating to dryness and again igniting, should leave a residue of bismuth oxide weighing not less than 0.52 Gm. nor more than 0.57 Gm." *U. S.*

Uses.—Bismuth subgallate was originally introduced into medicine as a substitute for iodoform in the treatment of eczema and other skin diseases, and in surgical dressings. It does not, however, act like iodoform, and is only a feeble germicide which resembles closely in all its

medicinal activities the older insoluble preparations of bismuth, than which it is, however, thought by some practitioners to be more astringent, and therefore preferable in *diarrhœa*; otherwise its rank in internal medicine is precisely that of the subnitrate.

Dose, seven to thirty grains (0.45 to 2.0 Gm.).

A process for bismuth subnitrate is no longer official in the U. S. or Br. Pharmacopœias. The process of the U. S. P. (1870) is given in the foot-note.¹

The alterations from the old process in the U. S. P. formula of 1870 were based upon the wish to get rid of any arsenic that might be present in the bismuth used. This is accomplished by first preparing the carbonate, by adding the nitric acid solution of bismuth to a solution of sodium carbonate in excess, whereby most of the arsenic is retained in the solution, probably as sodium arsenate, while the insoluble carbonate is precipitated. This is dissolved, with the aid of heat, in nitric acid,

so as to make a very concentrated solution of the nitrate, to which, when cold, just enough water is added to begin to produce a permanent turbidity. The object of this is to allow any arsenic that may be still present to be deposited, which happens for reasons stated in explaining the process for procuring the subcarbonate. (See page 240.) The deposited matter having been precipitated, only the pure nitrate remains in solution, which is made to yield the subnitrate by large dilution with water, and still more completely by the addition of ammonia.

In the former British formula, the method pursued was that of dissolving the bismuth, which has been previously purified, in nitric acid somewhat diluted, concentrating the solution, and precipitating by adding it to a large quantity of water. When bismuth is added to diluted nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder so as to form a solution of bismuth trinitrate. It is unnecessary to have the metal in powder, as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, and not the water to the solution. In order to have a smooth light powder, which is most esteemed, the precipitate should be well washed to remove every trace of free nitric acid, and dried as speedily as possible. In the use of this formula it is taken for granted that the bismuth has been ascertained to be free from arsenic; and if it prove upon the application of Marsh's test to be otherwise, means should certainly be employed to purify it before using it. Methods for this purpose are mentioned under *Bismuthum*. Should the subnitrate or subcarbonate be ascertained to contain arsenic, it may, as suggested by Herapath, be purified by boiling it with solution of sodium hydroxide twice successively, then thoroughly washing the residue, which will be yellow oxide of bismuth, dissolving it again in nitric acid, and precipitating by water as before. (*Chem. News*, 1863, p. 77.) In the washing of bismuth subnitrate, the salt is asserted to lose a portion of its nitric acid; and the change may be considerable, if the washing be continued so long as the liquid comes away in any degree acidulous. It has been ascertained by Julius Löwe that this effect may be avoided by washing with a very diluted solution of ammonium nitrate, containing one part in 500 parts of water. (*Chem. Gaz.*, March 15, 1859, 119.)² A. de

¹ Take of Bismuth, in pieces, two troyounces; Nitric Acid eight troyounces and a half; Carbonate of Sodium ten troyounces; Water of Ammonia five fluidounces; Distilled Water a sufficient quantity. Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water, in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. Dissolve the Carbonate of Sodium in twenty fluidounces of Distilled Water with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless, and drain again as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the Nitric Acid, and afterwards four fluidounces of Distilled Water, and set the solution aside. At the end of twenty-four hours, filter through paper, and to the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia with constant stirring. Transfer the whole to a strainer, and after the precipitate has been drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Lastly, dry it upon bibulous paper with a gentle heat, and rub into powder." *U. S.* 1870.

² In order to avoid the handling of large volumes of liquid, as well as the loss of bismuth by the production of soluble salts, A. Lalleu proposes the following process, which, he says, yields a much larger, purer, and denser product: 200 grammes of bismuth are dissolved in a sufficient quantity of nitric acid; the clear solution is decanted and poured into about 8 liters of water containing 500 grammes of ammonia water. The precipitate is washed, transferred to a dish and 50 to 60 grammes of caustic soda, dissolved in a little water, are added to it. The dish is then exposed for 15 to 20 minutes to the heat of a water bath, and the contents stirred up several times. After having again become cold, the super-

Schulten obtained *crystallized bismuth subnitrate*, $5\text{Bi}_2\text{O}_3 \cdot 5\text{N}_2\text{O}_5 \cdot 9\text{H}_2\text{O}$, by dissolving 50 Gm. of bismuth subnitrate in 50 Cc. of nitric acid (sp. gr. 1.2) and adding 300 Cc. of water while stirring; the crystals which are produced are pressed between folds of filter paper and dried. (*Chem. News*, 1904, 87.) *Bismuth nitrate*, a crystalline salt ($\text{Bi}_3\text{NO}_5 \cdot 5\text{H}_2\text{O}$), is deposited from a solution of bismuth in nitric acid. Bismuth nitrate has been used by Balmanno Squire dissolved in glycerin, under the name of *Glycerole of Nitrate of Bismuth*. (P. J., Nov. 11, 1876.) W. W. Moorhead prepares it by taking two troyounces of crystalline bismuth nitrate and dissolving in sufficient glycerin to make eight fluidounces. No heat should be used. This preparation can be diluted with an equal bulk or less of water, or one part can be added to forty-eight of water without precipitation, but one part to twelve, eight, or six of water soon precipitates. (*A. J. P.*, 1877, p. 98; also pp. 23 and 89.)

Properties.—Bismuth subnitrate is “a white powder, of somewhat varying chemical composition,¹ odorless and almost tasteless, and permanent in the air. Almost insoluble in water, and insoluble in alcohol, but readily soluble in nitric or hydrochloric acid. When heated to 120°C . (248°F .) for twelve hours the salt loses not over 3 percent. of moisture; when subsequently heated to redness it evolves nitrous vapors, leaving not less than 80 percent. of its weight of a yellow residue, which is soluble in nitric or hydrochloric acid and blackened by hydrogen sulphide. When brought in contact with moistened blue litmus paper the salt shows a slightly acid reaction. On adding 3 Gm. of the salt to 3 Cc. of warm nitric acid no effervescence should occur (absence of carbonate), and no residue should be left (absence of *insoluble foreign salts*). If this solution be poured into 100 Cc. of water, a white precipitate is produced. If the filtrate separated from this precipitate be evaporated on a water-bath to 30 Cc., the liquid again filtered, and the new filtrate divided into portions of 5 Cc. each, these should respond to the tests for purity described under *Bismuthi Subcarbonas*. On boiling 0.1 Gm. of the salt with 5 Cc. of potassium hydroxide T.S., no odor of ammonia should be perceptible. If 2 Gm. of the salt be heated in a porcelain crucible until nitrous vapors cease to be evolved,

the residue of bismuth oxide, when cold, should weigh not less than 1.6 Gm., and should not respond to Bettendorf's Test for arsenic (see PART III, Test No. 16).” U. S. The British Pharmacopœia describes it as “a heavy white inodorous powder consisting of minute crystalline scales, with not more than a slight action on *litmus*. It should answer to the general characters and tests enumerated under ‘Bismuth Oxycarbonate.’ Each gramme should yield 0.84 gramme of bismuth sulphide. It should afford only the slightest reactions with the tests for carbonates. If 1 gramme be dissolved in *nitric acid* and the liquid mixed with a solution of about 2 grammes of *citric acid* and sufficient solution of *ammonia* to give decided alkalinity, no precipitate or opalescence should be produced by boiling the mixture while still faintly alkaline (absence of calcium phosphate).” Br. It is readily soluble in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrogen sulphide gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If the nitric solution is not precipitated by diluted sulphuric acid, it is free from lead. It sometimes contains arsenic, which may be detected by acting on it with pure sulphuric acid, evaporating to dryness, dissolving in hot distilled water, and testing a part of the solution by Marsh's apparatus. By this method Lassaigne detected one-sixth of 1 per cent. of arsenic in a sample of subnitrate sold in Paris. Glénard proposed two other methods of searching for arsenic in the subnitrate, one merely qualitative, the other quantitative. The first consists in strongly heating a mixture of the suspected salt with potassium acetate. The least trace of arsenic will be detected by the strong and offensive odor produced, owing to the formation of cacodyl. In the second, the bismuth subnitrate is heated with pure hydrochloric acid. If arsenic be present it will rise in vapors in the form of chloride. These should be carefully collected and condensed and then treated with an excess of hydrogen sulphide. The arsenic sulphide precipitated will be the measure of the metal. (*Ann. Thér.*, 1868, p. 176.) Lassaigne has found as much as 27 per cent. of bismuth chloride in this preparation, when obtained by precipitating, with water, a solution of bismuth in a mixture of nitric and hydrochloric acids. The same impurity is introduced, to a small extent, by using common water containing chlorides; and bismuth subsulphate renders the preparation impure, when the water used contains calcium sulphate. These facts show the necessity of using distilled water. As regards the origin of the chlorine sometimes existing in commercial bismuth subnitrate, it was asserted by R. C. Tiebhorne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother liquor after the deposition of the subnitrate, to precipitate

the residue of bismuth oxide, when cold, should weigh not less than 1.6 Gm., and should not respond to Bettendorf's Test for arsenic (see PART III, Test No. 16).” U. S. The British Pharmacopœia describes it as “a heavy white inodorous powder consisting of minute crystalline scales, with not more than a slight action on *litmus*. Tiebhorne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother liquor after the deposition of the subnitrate, to precipitate

¹The British Pharmacopœia gives the following chemical composition: $\text{BiONO}_3 \cdot \text{H}_2\text{O}$.

it with sodium chloride, thus obtaining an insoluble bismuth oxychloride, which is then added to the previous product. (*P. J.*, 1860, 413.) For the modes of detecting and separating it, the reader is referred to the *Chem. News* (1863, p. 109). The metal thallium is said to be present in some specimens of the pharmaceutical preparations of bismuth, while the fetid odor of the breath so often produced when the subnitrate is administered is believed to be due to traces of tellurium. (Brownen, *P. J.*, Oct. 16, 1875.) It has also been said that the arsenic usually present in minute quantities is the cause of the garlicky odor of the breath. E. R. Squibb (*Ephem.*, Sept. 1882) states, however, that the "bismuth breath" has been noticed in patients who were taking a preparation of bismuth in which the absence of both tellurium and arsenic was conclusively shown. The cause of the peculiar odor is, therefore, at present doubtful. Calcium phosphate has been ascertained to be an occasional adulteration of the subnitrate. A ready method of detecting it suggested by Roussin, has proved to be fallacious, and may lead to false decisions as to the presence of the phosphate. There can be no difficulty in detecting the adulteration by the U. S. P. tests. Bismuth subnitrate was called by the earlier chemists *magistery of bismuth*. It is incompatible with potassium iodide (slowly forming a brick-red bismuth iodide) and with alkaline bicarbonates. For examination of commercial bismuth subnitrate by Curtman, see *A. J. P.*, 1896, 422; *Ph. Era*, 1896, 43; also a paper by F. A. Upsher Smith (*P. J.*, 1900, 15).

Uses.—The great insolubility of bismuth subnitrate has led to the belief that it is not absorbed in the gastro-intestinal tract, but the finding of it by Orfila in the spleen and liver, by Lewald in the milk, by Bergeret and Mayençon and other chemists in the urine, proves that the slow absorption of the drug does take place. The largest doses, however, given internally, never produce any general sensible effect upon the system, the remedy being employed solely for its soothing, sedative, feebly astringent influence upon the mucous membrane. It is very useful in *subacute gastritis*, *gastralgia*, *pyrosis*, and allied *stomachic disease*, in which affections it should be given before or just after meals; when given one to two hours after meals, the subnitrate escapes with the contents of the stomach into the intestines, and is very useful in conditions of *irritation of the intestinal mucous membrane*. It may be employed in *diarrheas of irritation*, and even in *dysentery*, but in *diarrheas of relaxation* it is of little service. Its use produces dark green or blackish discoloration of the stools. Bismuth subnitrate is also a very useful topical application in various mucous inflammations, other than gastro-intestinal; thus, it is used with advantage by injection (5 to 20 gr. to 1 fl. oz. of mucilage) in the first stage of *gonorrhœa*, in *leucorrhœa*, in *dysentery*, and in *rectal irritation*, and by snuff-

ing in *coryza*, etc. The dose of bismuth subnitrate is from five to forty grains (0.32 to 2.6 Gm.), three or more times a day, the large dose being employed in *diarrhœa*. Even in much larger amounts than those mentioned the medicine is practically safe; the symptoms described by Orfila and other early toxicologists as produced by it having been undoubtedly due to irritant impurities which formerly existed in the drug.

As has been shown by Theodore Kocher, even the insoluble preparations of bismuth are active antiseptics, and they were for a time much used in Germany in the treatment of *wounds*. It was claimed for them that they acted like iodoform and were not capable of producing poisonous symptoms. Further experience has shown, however, that this is incorrect; that when applied in large quantities to extensive wounded surfaces they are capable of yielding so much bismuth to absorption as to produce a poisoning, which is characterized by acute stomatitis, with a peculiar black discoloration of the mucous membrane, usually beginning upon the borders of the teeth, but spreading over the whole mouth, followed by an intestinal catarrh, with pain and diarrhœa; in severe cases desquamative nephritis, as shown by albuminous urine and epithelial tube casts, may also occur.

Dose, five to thirty grains (0.32 to 2.0 Gm.).

BISMUTHI SUBSALICYLAS. U. S. (Br.)

BISMUTH SUBSALICYLATE

(biſ-mŭ'thī sŭb-sāl-i-cy'lās)

"Bismuth Subsaliolate should yield not less than 62 nor more than 64 percent. of pure bismuth oxide." *U. S.* "Bismuth Salicylate, or oxysaliolate, $C_6H_4.OH.CO.O.BiO$ may be prepared by the interaction of bismuth nitrate and sodium salicylate." *Br.*

Bismuthi Salicylas, *Br.*; Bismuth Salicylate; Bismuthyl Salicylate, Bismuth Oxysaliolate; Salicylate Basique de Bismuth, *Fr. Cod.*; Sous-saliolate de Bismuth, *Fr.*; Bismutum subsalicylicum, *P. G.*; Basisches Wismutsaliolat (salicylsaures Wismutoxyd), *Wismutsalsaliolat*, *G.*; Salicilato de bismuto, *Sp.*

Preparation.—This salt is a bismuthyl salicylate of definite composition, the bismuth oxide resulting from its ignition being about 64 percent. Samples which show a higher percentage than this either contain bismuth subnitrate or hydroxide. It may be made by Wolff's process, by diluting a glycerin solution of crystallized bismuthous nitrate with one or two parts of water, and decomposing this with a concentrated aqueous solution of sodium salicylate, then washing the precipitate well with hot water and carefully drying. Another method for its preparation will be found in *A. J. P.*, 1891, 401. Fischer and Grützner (*A. Pharm.*, 1894, 680) object to the variable composition of commer-

cial bismuth saliicylate, and recommend the following process for making a basic salt of constant composition. Crystallized bismuth nitrate is dissolved in four times its weight of diluted acetic acid, the solution diluted with about forty times its weight of water, and the bismuth precipitated as hydroxide by ammonia water. The precipitate is washed and mixed with the molecular proportion of saliicylic acid. After heating on a water bath, a magma of crystals of basic bismuth saliicylate is formed; these are drained and dried. B. Fischer recommended the following process: one molecule each of saliicylic acid and freshly precipitated bismuth hydroxide are heated together with the necessary amount of water on the water bath; filter, collect and dry the residue at 80° to 100° C. (176° to 212° F.) on porous tiling. (*Ph. Centralt.*, 1895, 92, 169.) Duyk prepares bismuth saliicylate as follows: 100 Gm. of pure bismuth subnitrate are treated for one or two days with one liter of water, to which 50 Gm. of ammonia water have been added. After shaking sufficiently the subnitrate is completely changed into an oxide, which is collected and carefully washed with water. This oxide, after expression, is heated, under constant stirring, with 25 Gm. powdered saliicylic acid on a water bath. After the union has been effected, the saliicylate is washed and dried at a gentle heat (*B. S. Ph. Br.*, 1891). Thibault prefers the use of crystallized bismuth nitrate and solution of sodium hydroxide to precipitate the bismuth hydroxide (*Bull. Soc. Chem.*, xxv. No. 16).

Properties.—Bismuth subsaliicylate, termed bismuth saliicylate in the British Pharmacopœia, was introduced into the U. S. Pharmacopœia (8th Rev.) for the first time and is officially described as "a white, or nearly white, amorphous or crystalline powder, odorless, tasteless, and permanent in the air. Almost insoluble in cold water; upon prolonged boiling with water a portion of the saliicylic acid passes into solution with the formation of a more basic bismuth saliicylate. It is partly soluble with decomposition in hydrochloric and nitric acids, a white, flocculent precipitate of saliicylic acid separating. When heated at 120° C. (248° F.) Bismuth Subsaliicylate should not lose more than 1 percent. of water, and on subsequently heating to redness it at first chars, finally leaving a yellow residue, which is soluble in hydrochloric or nitric acid and is blackened by ammonium sulphide T.S. When Bismuth Subsaliicylate is agitated with a solution of 5 drops of ferric chloride T.S. in 10 Cc. of water, a deep violet-blue coloration is produced. If 1 Gm. of Bismuth Subsaliicylate be thoroughly agitated with 10 Cc. of diluted hydrochloric acid and filtered, the residue, after washing and drying, should conform to the reactions and tests given under *Acidum Saliicylicum*. Upon pouring the filtrate into an excess of water, a heavy white precipitate of basic bismuth chloride should be obtained. If 1 Gm. of the salt be agitated with 5 Cc. of chloroform, and

the liquid filtered through a double filter of fine texture into 5 Cc. of water containing 3 drops of ferric chloride T.S., no violet zone should form within five minutes at the line of contact of the two liquids (absence of *free saliicylic acid*). If 3 Gm. of Bismuth Subsaliicylate be ignited in a porcelain crucible, and, after cooling, nitric acid be cautiously added to the residue, solution should be complete if gently heated; if this solution, after concentrating to about 4 Cc., be poured into 100 Cc. of water, and after filtering and evaporating the filtrate on a water-bath to 30 Cc., again filtering, and dividing this filtrate into portions of 5 Cc., then each of these should respond to the tests for purity described under *Bismuthi Subcarbonas*. If 0.2 Gm. of Bismuth Subsaliicylate be triturated with 0.3 Gm. of sodium saliicylate and 5 Cc. of distilled water, and carefully poured, without mixing, over 5 Cc. of sulphuric acid (free from nitrous compounds) contained in a test-tube, no pink to brownish-red zone should form immediately (limit of *nitrates*). The residue resulting from the ignition and subsequent treatment of 2 Gm. of the salt, as described below, should not respond to Bettendorf's Test for *arsenic* (see PART III, Test No. 16.). If 1 Gm. of Bismuth Subsaliicylate, dried at 120° C. (248° F.), be thoroughly ignited in a porcelain crucible, and, after cooling, 5 Cc. of nitric acid be added to the residue, drop by drop, warming until complete solution has been effected, this, upon evaporating to dryness and again igniting, should leave a residue of bismuth oxide weighing not less than 0.62 Gm. nor more than 0.64 Gm." *U. S.* The British Pharmacopœia describes this salt as "a white or nearly white amorphous powder, insoluble in water. It affords the reactions characteristic of bismuth. Diluted *test-solution of ferric chloride* is colored violet when Bismuth Saliicylate is introduced. It should yield only the faintest characteristic reaction with the copper test for nitrates. *Alcohol* (90 per cent.), with which Bismuth Saliicylate has been shaken, should not give a violet color with *test-solution of ferric chloride* (absence of free saliicylic acid). Decomposed by heating with *solution of sodium carbonate*, the liquid portion of the resulting mixture, if containing not less than 1 per cent. of saliicylate, affords a yellowish-brown precipitate on the addition of *solution of uranium nitrate* (distinction from carbonates and sulphocarbonates). Each gramme of Bismuth Saliicylate should yield 0.7 gramme of bismuth sulphide. When heated, saliicylic acid volatilizes and 62 to 64 per cent. of bismuth oxide remains. It should be free from the impurities indicated under 'Bismuth Oxycarbonate.'" *Br.*

Uses.—Bismuth subsaliicylate was originally proposed as an intestinal antiseptic and feeble astringent, and has been used to a considerable extent in the treatment of chronic *intestinal catarrhs* and subacute *diarrhœas* with marked tendency to intestinal fermentation; also as a

local antiseptic remedy for wounds and various inflammations of the mucous membrane. We have never been able to perceive that it is more effective or different in its action from the older preparations of the metal.

Dose, from ten to twenty grains (0.65 to 1.3 Gm.), every four to eight hours.

BISMUTHUM.

BISMUTH

(biş-mū'thūm)

Bi = 206.9

Etain de Glace, Bismuth, *Fr.*; Wismuth, Wismut, *G.*; Bismuto, *It.*, *Sp.*

Bismuth occurs usually in the metallic state, occasionally as a sulphide or a telluride, and rarely as an oxide. It is found largely in Saxony, Schneeberg being the chief point of production. It has been found, mainly as telluride of bismuth, in Colorado with gold and silver ores. Small quantities have been found in Utah and Wyoming. It has also been discovered in Southern Australia, from whence a quantity of it has been sent into commerce. It is obtained almost entirely from native bismuth, which is heated by means of wood or charcoal, whereby the metal is fused, and separated from its gangue. Most of the bismuth of commerce comes from Saxony, although it is now also largely mined in Bolivia. The bismuth ore from South America is said to be naturally free from arsenic, and to be therefore preferable for pharmaceutical purposes.

As the production of bismuth in the world far exceeds the demand, there is no regular American production, much of that which accompanies the gold and silver in the ore being allowed to go to waste in the slag.

Bismuth was first recognized as a metal by Agricola in 1520. Before that period it was confounded with lead. It is a brittle, pulverizable, brilliant metal, of a crystalline texture, and of a white color with a slight reddish tint. Its crystals are rhombohedral, but with an angle of $87^{\circ} 40'$, which makes it difficult to distinguish them from cubes, in which the angle would be 90° . Indeed, many books still refer to it as cubical in form. It undergoes but a slight tarnish in the air. Its sp. gr. is 9.8 (B. P. 1885, purified 9.83), melting point 264° C. (507° F.). When impure bismuth solidifies after fusion, globules of the metal, nearly pure, are thrown up from the mass. This takes place when the metal contains as much as 50 per cent. of impurity. The same phenomenon does not occur when pure bismuth is melted. (R. Schneider.) At a high temperature, in close vessels, bismuth volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a faint blue flame, forming an oxide of a yellow color. This is the *trioxide*, and consists of two atoms of bismuth and three of oxygen. There is another compound of bismuth and oxygen consisting of

two atoms of the former and five atoms of the latter, which is called *bismuthic oxide*, Bi_2O_5 . It is obtained in the form of a hydroxide by boiling bismuth nitrate in solution of potassium hydroxide, washing the precipitate, and mixing it while moist with solution of potassium hydroxide into which chlorine is passed. A mixture of bismuthous and bismuthic oxides is precipitated, from which the former is separated by digestion with nitric acid. The hydroxide remaining, when washed and dried, is in the form of a red powder, which gives up its water at 130° C. (266° F.), and at a higher heat loses oxygen. Bismuth is acted on feebly by hydrochloric acid, but violently by nitric acid, which dissolves it with a copious liberation of red fumes. Sulphuric acid, when cold, has no action on it, but at a boiling heat effects its solution with the liberation of sulphurous acid. As it occurs in commerce, it is generally contaminated with other metals, among which are arsenic in minute quantity, traces of silver, cadmium, nickel, lead and iron, and sometimes a very small proportion of thallium. Claassen has found in so-called "purissimus" bismuth, lead, copper, and iron, and in one sample of bismuth, sold as suitable for scientific purposes, he obtained from 500 grammes 10 grammes of lead chloride. (*Ap. Ztg.*, 1891, p. 121; see also *Chem. News*, 1892, lxx. 28.) It may be purified from all contaminating metals by dissolving the bismuth of commerce in diluted nitric acid, precipitating the clear solution by adding it to water, and reducing the white powder thus obtained with black flux. The same precipitate is obtained by adding ammonia to the nitric solution; if the supernatant liquid is blue, the presence of copper is indicated; if the precipitate is yellowish, iron is present. The British Pharmacopœia (1885) contained a process for purifying bismuth which was not introduced in the 1898 edition of the same authority. (See U. S. D., 17th ed., p. 270.)

Uses.—Bismuth is not used in medicine in an uncombined state, but is employed pharmaceutically to obtain bismuth subcarbonate, subnitrate, subgallate, subsalicylate and other medicinal preparations formed from this metal. In the arts its oxychloride is used to form a cosmetic for the complexion, called *pearl white*, and the metal as an ingredient of the best pewter.

BROMOFORMUM. U. S.

BROMOFORM

(brō-mō-fōr'mūm)

"A liquid consisting of 99 percent., by weight, of absolute Bromoform [$\text{CHBr}_3 = 250.99$], and 1 percent. of absolute alcohol. It should be kept in dark amber-colored, glass-stoppered bottles, in a cool place, protected from light." U. S.

Tribrommethane, Formyl Tribromide; Bromoformum, *P. G.*; Bromoform, Tribrommethan, *G.*; Bromoformo, *Sp.*

This compound, the analogue of chloroform, is prepared by methods similar to those used for the manufacture of chloroform. It is made, for instance, by the action of bromine in the presence of calcium hydroxide upon alcohol or acetone, or by the decomposition of bromal (the analogue of chloral) by alkalies. It is found as an impurity, at times, in commercial bromine.

Bromoform is officially described as "a heavy, transparent, colorless, mobile liquid, with an ethereal odor, and a penetrating, sweet taste resembling that of chloroform. Specific gravity: 2.808 at 25° C. (77° F.). Very slightly soluble in water, but soluble in all proportions in alcohol, ether, benzene, petroleum benzin, and in the fixed and volatile oils. Bromoform is slightly volatile at ordinary temperatures, boils at 148° C. (298.4° F.), and solidifies at 6° C. (42.8° F.). It is not inflammable, but when vaporized by the application of heat, its vapor may be burned. If 10 Cc. of Bromoform be evaporated in a dish over a naked flame, no solid residue should remain. If 10 Cc. of Bromoform be well shaken with 10 Cc. of distilled water, and the liquids, upon standing, be allowed to separate completely, the water removed from the layer of Bromoform should be neutral to blue litmus paper (absence of free acid), and a portion should not produce a turbidity when treated with silver nitrate T.S. (absence of bromides and brominated compounds), and another portion treated with potassium iodide T.S. should not be tinted blue upon the addition of starch T.S. (absence of free bromine). If 10 Cc. of Bromoform be well shaken with 10 Cc. of distilled water, and the liquids, upon standing, be allowed to separate completely, the water removed from the Bromoform, treated with an excess of ammonia water, and then with a solution of iodine and ammonium iodide, until the black precipitate of nitrogen iodide, which may sometimes form, slowly disappears, it should not become milky in appearance, due to the separation of iodoform, which may be recognized by its odor (absence of acetone)." *U. S.*

Uses.—As long ago as 1849, Nunneley and Schuchard suggested the use of bromoform as a general anæsthetic. The later experience of practical surgeons has shown, however, that although bromoform produces a rapid narcosis when inhaled, its employment is attended with excessive danger. When taken internally by the mouth it is capable of acting like the older bromides, over which, however, it has no advantages and than which it is probably more dangerous. In the recorded cases of poisoning by it the symptoms have been pallor, titubation, dilatation of the pupils, coma, heart failure and collapse.

The original statement by Stepp, that bromoform is especially efficient in *whooping cough*, has been confirmed by various clinicians. Stepp administered in a teaspoonful of water to children three or four weeks old, one drop three or four times daily; in older, nursing children,

three drops; in children from two to four years of age, four to five drops three or four times daily; up to seven years of age six to seven drops three or four times daily. These doses are, however, probably dangerous. Three drops are said to have produced very serious symptoms in a child of four years, and two drops in one of fifteen months. For cases of poisoning see *Cb. I. M.*, No. 50, 1902; *B. M. J.*, vol. i, 1900; *T. G.*, 1903; *Ap. Ztg.*, July, 1898, March 24, 1900.

Dose, one to five minims (0.06 to 0.3 Cc.), best administered in capsules, dropped on sugar, or mixed with an equal quantity of olive oil and emulsified.

BROMUM. U. S.

BROMINE

(brō'mūm)

Br = 79.36

"It should contain not less than 97 per cent. of pure Bromine, and be kept in protected glass-stoppered bottles, in a cool place." *U. S.*

Brominium, U. S. 1870; Brome, Fr. Cod.; Bromum, P. G.; Brom, G.; Bromo, It., Sp.

Bromine is an elementary body, possessing many analogies to chlorine and iodine. It was discovered in 1826 by Balard of Montpellier, in the bittorn of sea salt works, in which it exists as a magnesium bromide. Since then it has been found in the waters of the ocean, in certain marine animals and vegetables, in various aquatic plants, as the water cress, in numerous salt springs, and in the mineral kingdom. It has also been detected by Mène in the coal gas liquor of the Paris gas works. In the United States it was first obtained by Silliman, who found it in the bittorn of the salt works at Salina, in the State of New York. It was discovered in the salt wells near Freeport, Pa., by David Alter, and is now obtained in largest amount from the brines of Ohio, Pennsylvania, Michigan, and West Virginia. The chief works are located at Parkersburg and Mason City, W. Va.; Pomeroy, Ohio, and Midland County, Mich. The annual production of bromine in the United States for the last few years has been as follows: 1903, 598,500 lbs., valued at \$167,580; in 1904, 897,100 lbs., valued at \$269,130; and in 1905, 899,434 lbs., valued at \$139,432. The bromides contained in the mother liquors of the salt wells are oxidized by manganese dioxide in West Virginia and Ohio, while potassium chlorate is the favorite oxidizing agent in Michigan, because of the large proportion of calcium chloride in the liquor. Much is also produced in the latter State by electrolytic processes.

Preparation.—The original salt liquor or brine is pumped out of the ground at 9° B., evaporated to about 15° in large iron pans, then allowed to settle, and is further evaporated in wooden tanks heated by steam pipes to the

point of crystallization of the salt. These tanks, five in number, are placed at different elevations, one above the other. Each day the liquor is run off from No. 1, the highest, to No. 2, next day to No. 3, and so on until it reaches No. 5, the crystallized salt being removed from each tank after draining off the liquor. The brine which reaches No. 5 is bitter, and consists chiefly of calcium, magnesium, sodium, and some aluminum chlorides, with varying percentages of sodium and calcium bromides.

The bitter marking 30° to 38° B. is evaporated to about 45° B. By this further evaporation an additional percentage of impure salt is removed; the liquor is then run into stone stills, materials for generation of chlorine added, and heat applied by means of steam until the bromine has been all eliminated and vaporized. It is condensed and collected in cooled receivers. (*Proc. A. Ph. A.*, 1877, p. 448.) A bromine still is figured in *N. R.*, April, 1877; see also *N. R.*, 1883, 108; *Am. Drug.*, 1884, 121. The chief source of the bromine abroad is at Stassfurt in Germany, where the magnesium bromide remains as a residue in the working of the potassium salts. The bromine is extracted from the solution of bromide in a continuous process by the joint action of chlorine gas and steam.

Bromine has also been obtained from sea weeds by carbonizing them, lixiviating the carbonaceous residue, and then separating the ingredients, among which are iodine and bromine. For details, see *Chem. News* (July 6, 1866, p. 2). More than two-thirds of the bromine of commerce is used for the manufacture of bromides for medicinal use, and for photography; the remainder is used for aniline colors.

Properties.—Bromine is a volatile liquid, of a dark red color when viewed in mass, but hyacinth-red in thin layers. Its taste is very caustic, and its odor intensely strong and disagreeable, having some resemblance to that of chlorine.¹ Its sp. gr. is very nearly 3 (2.99). *U. S.*, 2.97 to 3.14, *Br.* (1885). At -24.5° C. (-12° F.), Baumhauer,² (-7.2° C., Philipp) it becomes a hard, brittle, crystalline solid, having a dark leaden color, and a lustre nearly metallic. It boils at about 63° C. (145.4° F.), forming a reddish vapor resembling that of nitrous acid, and of the sp. gr. 5.54. It evaporates readily, a single drop being sufficient to fill a large flask with its peculiar vapor.

Bromine is sparingly soluble in water [in 28 parts at 25° C. (77° F.)], *U. S.*], to which it communicates an orange color, more soluble in alcohol, and still more so in ether, chloroform, and carbon disulphide. By the aid, however, of potassium bromide, it may be dissolved

to any desirable extent in water. Its alcoholic and ethereal solutions lose their color in a few days, and become acid from the generation of hydrobromic acid. It bleaches vegetable substances like chlorine, destroys the color of indigo sulphate, and decomposes organic matters. Its combination with starch has a yellow color. It corrodes the skin and gives it a deep yellow stain. Bromine is intermediate in its affinities between chlorine and iodine, since its combinations with metals are decomposed by chlorine, while, in its turn, it decomposes those of iodine. It forms acids which are analogous in properties and composition to the corresponding acids of chlorine and iodine. It combines also with chlorine, forming bromine chloride, which probably has the formula BrCl_3 . This is prepared by passing chlorine through bromine, and condensing the vapors at a low temperature. It is a reddish-yellow liquid, very volatile, soluble in water, with a penetrating odor and disagreeable taste.

Commercial bromine sometimes contains as much as 6 or 8 per cent. of carbon tetrabromide, as ascertained by Poselger. He discovered the impurity by submitting some bromine to distillation, during the progress of which the boiling point rose to 120° C. (248° F.). The residuary liquid at this temperature was colorless, and when freed from a little bromine, proved to be carbon bromide, as an oily, aromatic liquid. It is stated by T. L. Phipson that he has found in commercial bromine, accounted pure, a notable amount of cyanogen, and that it may be detected as follows. Take of iron filings and bromine, of each, half an ounce; add to the filings 2 or 2.5 ounces of water; introduce the bromine very gradually, stirring steadily; filter rapidly while warm from the reaction; and put the filtered liquid in a partially closed bottle. In the course of some hours a deposit of iron ferri-cyanide (Berlin blue) will have formed, and may be collected on a filter. In about two days the whole of the cyanogen will be deposited. In the samples of bromine thus examined he had found from 0.5 to 1 per cent. of cyanogen. (*Chem. News*, 1873, p. 51.) Chlorine and iodine are frequently found in bromine, the former being more common in American and the latter in German bromine.

The U. S. P. gives the following description, with tests for the purity of bromine. "A heavy, dark brownish-red, mobile liquid evolving, even at ordinary temperatures, reddish fumes, highly irritating to the eyes and lungs, and having a peculiar suffocating odor, resembling that of chlorine. Specific gravity: 2.990 to 3.000 at 15° C. (59° F.). Boiling point, 63° C. (145.4° F.). Soluble in 28 parts of water at 25° C. (77° F.), and readily soluble in alcohol or ether (with gradual decomposition of these liquids); also in carbon disulphide, and in chloroform, with a deep reddish-yellow color. On exposure to air or to heat, it is completely volatilized without leaving any residue.

¹ Inhaled in the form of vapor it produces great irritation, and endangers asphyxia through spasm of the glottis. A case which had nearly proved fatal was apparently saved by throwing steam sufficiently cooled into the larynx. (G. P. Duffield, *A. J. P.*, 1868, p. 288.)

² See *A. J. P.*, Oct. 1872, p. 452. The higher degree usually given in chemical works is ascribed by Baumhauer to the presence of water in the bromine examined.

It destroys the color of solutions of litmus and indigo, and imparts a yellow color to solution of starch. If Bromine be added to an excess of potassium hydroxide T.S., it should combine to form a permanently clear liquid, without the separation of oily drops (absence of *organic bromine compounds*). If an aqueous solution of Bromine be shaken with a slight excess of reduced iron until it becomes nearly colorless, the filtered liquid, on the addition of a small amount of ferric chloride and of starch T.S., should not assume a blue color (absence of *iodine*.)" U. S.

In testing for bromine in mineral or saline waters, the water is evaporated in order to crystallize most of the salts. The solution, after having been filtered, is placed in a narrow tube, and a few drops of strong chlorine water are added. If this addition produces an orange color, bromine is present. The water examined, in order that the test may succeed, must be free from organic matter, and the chlorine not be added in excess. Bromine may be detected in marine vegetables by carbonizing them in a covered crucible, exhausting the charcoal, previously pulverized, with boiling distilled water, precipitating any alkaline sulphide present in the solution by zinc sulphate, and then adding successively a few drops of nitric acid and a portion of ether, shaking the whole together. If bromine be present it will be set free and dissolve in the ether, to which it will communicate an orange color. (Dupasquier.) According to Reynoso, a more delicate test is furnished by hydrogen dioxide, which liberates bromine from its compounds without reacting on it when free. The mode of procedure is as follows. Put a piece of barium dioxide in a test tube, and add successively, distilled water, pure hydrochloric acid, and ether. The materials are here present for generating hydrogen dioxide; and as soon as bubbles are seen to rise to the surface, the substance suspected to contain bromine is added, and the whole shaken together. If a bromide be present, the hydrochloric acid will give rise to hydrobromic acid; and the hydrogen dioxide, acting on this, will set free the bromine, which will dissolve in the ether, and give it a yellow tint and the odor of bromine.

Uses.—Bromine was formerly employed as an alternative in *bronchocele*, *scrofulous tumors* and *ulcers*, *syphilis*, *diseases of the skin*, and other chronic affections, but at present it is very rarely used. About six minims (0.4 Cc.) of an aqueous solution containing one part of bromine to forty of distilled water may be taken several times a day in water. Locally in its concentrated state it is a very powerful and deep caustic. When used as a wash for *ulcers*, from ten to forty minims may be added to a pint of water. The use of bromine as a caustic in *hospital gangrene* was proposed by Goldsmith during the Civil War, and became universal in the army hospitals. Applied pure by means of a glass rod, it destroyed the diseased tissues more rapidly

and thoroughly than did even strong nitric acid. Of the compounds of bromine, the potassium, ammonium, iron, and mercury bromides have been chiefly used. Some of them have been found to exercise a remarkable influence in allaying *nervous irritation*, and are now much employed for that purpose. See these titles respectively in the different parts of this work.¹ *Bromine chloride* has been used in *cancer* by Landolfi of Naples, both externally as a caustic and internally; but a committee of the French Academy reported decidedly against it.

J. Lawrence Smith of Louisville, Ky., proposed the following as a convenient formula for a solution of bromine. Dissolve 160 grains of potassium bromide in two fluidounces of water, add one troyounce of bromine, and, stirring diligently, pour in sufficient water to make the solution measure four fluidounces. The solution should be kept in accurately stoppered bottles. This is a suitable preparation for application to hospital gangrene, and may be diluted to any desirable extent with water. (*A. J. P.*, 1863, p. 202.)

Bromine is a very active germicide, but as such is not of practical value. In overdoses it is a corrosive poison. About an ounce ingested caused violent inflammation of the lips, mouth, tongue, and cesophagus, with incessant burning pain, followed, in two hours and a half, by prostration, ending in death. (Snell, *N. Y. Journ. of Med.*, Sept. 1850.) The best antidote, according to Alfred Smee, is ammonia, given largely diluted and mixed with sweet oil.

Bromine is extensively used in the manufacture of bromides, in photography, and in the manufacture of coal tar colors.

BUCHU. U. S. (Br.)

BUCHU

(bū'chū)

"The dried leaves of *Barosma betulina* (Thunberg) Bartling and Wendland (Fam. *Rutaceæ*)." U. S. "The dried leaves of *Barosma betulina*, Bart. and Wendl." Br.

Bucha Folia, Br.; *Folia Bucco*, *Folia Diosmæ*, s. *Barosmæ*; *Feuilles de Bucco* (Booko, Buchu), Fr.; *Buckublätter*, *Buccoblätter*, G.

The leaves of the official and other *Barosmas* (so named from βαρύς, heavy, and βούχ, odor), and of some *Agathosmas*, are collected by the Hottentots, who value them on account of their odor, and, under the name of *bookoo* or *buchu*, rub them, in the state of powder, upon their greased bodies.

¹ *Iodine bromide* in aqueous solution is sometimes employed, which is made by rubbing 10 parts of iodine with 40 parts of distilled water, introducing into a flask, adding 20 parts of bromine, and shaking until the iodine is dissolved. 530 parts of distilled water are added, and the whole filtered. 20 parts contain 1 part of iodine tribromide. A solution containing 15 per cent. is sometimes found in commerce.

The United States and British Pharmacopœias are at present in accord in acknowledging as "buchu" the product of a single species; formerly several other species were also recognized as the source of Buchu, and *B. serratifolia* is still official in some of the European countries. The medicinal species are all erect, slender shrubs with opposite leaves, dotted with conspicuous pellucid oil glands, smooth, angular, purplish branches, often of a purplish color, white flowers, and a fruit of five erect carpels. They are chiefly distinguished by their leaves.

Barosma betulina.—The leaves are cuneate-ovate, apex recurved, with their margin sharply denticulate by spreading teeth. They are from one-half to three-fourths of an inch long, by three-tenths to five-tenths of an inch wide. The non-official species, which have been seen in European markets occasionally, are said to be used in South Africa as substitutes for the official buchu; they are:

Barosma crenulata (L), Hook. (*B. crenata*, Lindl.; *Diosma crenata*, De Cand.)—The leaves are opposite, ovate or obovate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and stand solitarily at the end of short, lateral leafy shoots.¹

Barosma Eckloniana, Barth., a plant which has been considered to be only a variety of *B. crenulata*, has leaves which are rounded at the base, shorter and proportionately wider than those of *B. crenulata*, and also grow upon pubescent shoots.

B. serratifolia (Curt.), Willd.—The leaves are linear lanceolate, equally narrowed towards either end, three-nerved, with a truncate apex, which is always furnished with an oil-cell, and a sharply serrulate margin. Their length is from an inch to an inch and a half; their width one-fifth of an inch.

The leaves of *Barosma venusta*, which are said to have appeared in the London markets, are readily distinguished by their being very much smaller than those of *B. betulina*, which they otherwise resemble.

Under the name of *Karoo buchu*, in 1904 the leaves of the *Diosma succulenta*, L., var. *B. Bergiana*, H. and S., appeared in London; they are small and heath-like, thick, obtuse, and slightly recurved, and yielded to C. E. Sage (*C. D.*, 65, 506, 787) a semi-solid volatile oil having the odor of peppermint.

Properties.—Buchu leaves are officially described as "about 15 Mm. long, varying between oval and obovate, yellowish-green, apex obtuse, margin crenate or serrate with a gland

at the base of each tooth, the base more or less wedge-shaped; coriaceous, both surfaces beset with numerous slight projections; odor strong and characteristic; taste somewhat mint-like, pungent and bitterish." *U. S.* "The transverse section exhibits an epidermis whose cells contain yellow spherocrystals; the inner walls of these cells are thick and rich in mucilage. Odor and taste strong and characteristic." *Br.* The leaves of *B. crenulata* constitute the *short buchu* or *round buchu*, while those of *B. serratifolia* are the *long buchu* of commerce. The leaves of *B. crenulata* are at present comparatively infrequent in commerce, the parcels usually consisting of those of one of the other species almost unmixed. The species can be recognized by the characters already given. The leaves of the *Empleurum serrulatum* sometimes occur mixed with buchu leaves, occasionally constituting the bulk of the parcel. They are to be distinguished by their acrid taste and peculiar odor and by being longer and narrower than any buchu leaf, with a sharp-pointed apex, parallel sides, and coarse denticulation. Further, according to Holmes, when the leaf of a *Barosma* is held up to the light the lateral veins appear straighter, longer, and more strongly developed than in the leaves of the *Empleurum*. John C. Umney (*P. J.*, March, 1895) finds that the leaves of the latter contain 0.64 per cent. of a peculiar volatile oil. There is no reason to believe that they possess the therapeutical properties of buchu. Holmes enumerated a number of plants used in South Africa as substitutes (see *P. J.*, 1900, 70).

Flückiger obtained from *B. betulina* 1.56 per cent. of volatile oil, which had the odor of peppermint rather than of buchu, and deviated the plane of polarization considerably to the left. On exposure to cold it furnished a camphor, which, after re-resolution in alcohol, crystallized in needle shaped forms. After repeated purification in this manner, the crystals of *Barosma camphor*; or *diosphenol*, $C_{10}H_{16}O_2$, have a peppermint odor; they fuse at 85° C. and begin to sublime at 110° C. After fusion they again solidify only at 50° C. *Barosma camphor* is abundantly soluble in carbon disulphide. The crude oil from which the camphor had been separated had a boiling point of about 200° C., quickly rising to 210° C. or even higher. The oil which distilled between these temperatures, rectified over sodium, gave approximately the formula $C_{10}H_{16}O$. (*Pharmacographia*, 2d ed., p. 109.) Spica examined *B. crenulata* and found the volatile oil to differ from that obtained by Flückiger from *B. betulina*; the solid body was similar to diosphenol, but upon analysis gave the figures $C_{10}H_{16}O_2$, and hence is regarded by Spica as an oxycamphor. The liquid portion was a greenish-yellow oil, having a pleasant odor and a pungent, peppermint-like taste; by fractioning, it was separated into a portion isomeric with borneol, resembling thymol in odor and taste, to which the name of *dioscamphor* was given. A sub-

¹ C. J. S. Thompson has found that the leaves of *B. serratifolia* yield only 3.45 per cent. of resin and 1 per cent. of volatile oil, while those of *B. crenulata* yield 3.75 per cent. of resin and 1.6 per cent. of volatile oil, and those of *B. betulina* give 4.25 per cent. of resin and 1.45 per cent. of volatile oil; so that *B. serratifolia* would seem to be the least active of the species. (*P. J.*, xxi. 1890.)

stance extracted by alcohol from the residue after the removal of the oil *Spica* named *diosmin*. (*P. J.*, 1885, p. 106.) The results of *Spica* were confirmed by Shimoyama (*A. J. P.*, 1888, p. 624), who made several simple derivatives of diosphenol, and then prepared from it, by prolonged digestion with alcoholic potash, *diolic acid*, $C_{10}H_{18}O_8 + H_2O$, forming white crystalline needles, melting at 96° to 97° C., and a compound to which he gave the name *diol-alcohol*. Wayne's experiments (*A. J. P.*, 1876, p. 19) appear to indicate that the oil also contains a substance capable of being converted into salicylic acid. J. M. Maisch believed that buchu leaves do not contain salicylic acid, although the stearopten of the oil gives a blackish color with ferric chloride. (*A. J. P.*, July, 1881.) The yield of ash varies, according to the researches of H. W. Jones (*P. J.*, ix. 673), from 4.69 to 4.40 in *B. betulina*, 4.32 to 5.39 in *B. crenulata*, 5.03 to 5.22 in *B. serratifolia*; the ash itself was remarkable as containing a great deal of manganese. The short leaved buchu was found by P. W. Bedford to yield an average of 1.21 per cent. of volatile oil; while the long leaved, though more highly valued in the market, gave only 0.66 per cent., showing its great inferiority in strength. (*Proc. A. Ph. A.*, 1863, p. 211.)

Uses.—Buchu, originally employed by the Hottentots, has long since come into general use. Its activity depends upon the volatile oil, which is eliminated by the kidneys. Under its action there is no marked increase in the amount of the urine, hence the remedy is of no value in *dropsies*, but the oil affects very decidedly the mucous membrane of the genito-urinary tract. The remedy is very useful in *diseases of the urinary organs*, such as *gravel*, *chronic catarrh of the bladder*, *morbid irritation of the bladder and urethra*, *diseases of the prostate*, and *retention or incontinence of urine* from a loss of tone in the parts concerned in its evacuation. It should be given when the inflammation is not severe, but when it is in that condition of chronicity requiring oil of turpentine, tincture of cantharides, or other stimulant diuretics. An infusion (one ounce in a pint of boiling water) may be given in the dose of one to two fluidounces (30 to 60 Cc.), but the best preparation is the fluidextract.

Dose, one drachm (3.9 Gm.); of the fluidextract, a fluidrachm (3.75 Cc.), three or four times a day.

BUTYL-CHLORAL HYDRAS. Br.

BUTYL-CHLORAL HYDRATE

(bū'tyl-ehl'or'al hý'drās)

$C_4H_5Cl_3O.H_2O = 191.94$

"Butyl-Chloral Hydrate, or trichlorobutylidene glycol, $CH_3.CHCl.CCl_2.CH(OH)_2$, is a

crystalline hydrate obtained by the addition of water to the liquid butyl chloral produced by the action of chlorine gas on aldehyde." *Br.*

Butylchloralum Hydratum, Chloralhydratum Butyli; Trichlorobutylidene Glycol; Hydrous Butyl Chloral; Croton Chloral Hydrate (wrongly so called); Chloralum Butyli Hydratum; Butyl Chloralhydrate; Hydrate de Chloral Butylique, *Fr.*; Butylchloralhydrat, Trichlorobutylaldehydhydrat, *G.*

This substance was discovered by Krämer and Pinner of Berlin, during an examination of the accumulated by-products of the chloral factory of Schering. It was named croton-chloral hydrate because it was believed to bear a relationship to crotonic acid, the peculiar acid of croton oil; this was subsequently disproved by Pinner, who showed that it belonged to the butyl series. (*Ber. d. Chem. Ges.*, vii. 1321, 1561.) It is made by passing dry chlorine through aldehyde cooled to -10° C. (14° F.), in an apparatus similar to that used in making chloral. Fractional distillation is resorted to, and the product boiling between 163° C. (325.4° F.) and 165° C. (329° F.) is reserved; this is butyl-chloral, a colorless oily fluid. The necessary amount of water is added, and butyl-chloral hydrate is obtained.

Properties.—Butyl-chloral hydrate occurs in the form of crystalline, micaceous scales of a pungent odor, sparingly soluble in water, freely soluble in alcohol, hot water, and glycerin, but insoluble, or nearly so, in chloroform, a property which may be employed to separate it from ordinary hydrated chloral. When treated with caustic alkalies it is converted into formic acid, potassium chloride, and allylene dichloride, $C_3H_4Cl_2$. The British Pharmacopœia describes it as "in pearly white, trimetric laminae, having a pungent but not acrid odor, and an acrid nauseous taste. It fuses at about 172° F. (77.8° C.) to a transparent liquid, which, in cooling, commences to solidify at about 160° F. (71.1° C.). Soluble in about 50 parts of water, and in its own weight of glycerin or of alcohol (90 per cent.); it slowly dissolves in 20 parts of chloroform. The aqueous solution is neutral or but slightly acid to litmus. It does not yield chloroform when heated with solution of potassium hydroxide or with milk of lime (absence of chloral hydrate)." *Br.*

Uses.—Butyl-chloral hydrate was proposed by Liebreich, in 1870, as a remedy in the treatment of *trigeminal neuralgia*. He states that a drachm (3.9 Gm.) of it causes deep sleep, accompanied by anesthesia of the head, with complete loss of irritability of the eyeball and of the trigeminal nerve. The circulation is kept up with great tenacity, and, if the dose has been large enough, death results from the arrest of respiration. These statements of Liebreich were contradicted by the research of J. von Mering and of H. W. Schmidt, who found that no anesthesia was produced unless sufficient doses were given to cause complete narcosis, and that the general course of the symptoms caused by the butyl-chloral hydrate was exactly parallel to that of those produced by hy-

drated chloral. But a number of observers have used butyl-chloral hydrate with asserted good results in *tic-douloureux*. The relief obtained is, unfortunately, only temporary and palliative. The drug has been commonly administered in doses of from 5 to 20 grains (0.32 to 1.3 Gm.) in syrup. The safer plan is to give 5 grains (0.32 Gm.) every half hour until 30 grains (2.0 Gm.) have been taken or relief afforded. The original formula of Liebreich was—butyl-chloral hydrate 5 to 10 parts; glycerin 20 parts; distilled water 130 parts. Dose, half a fluidounce, followed in five minutes by a second dose, ten minutes later by a third dose, unless relief is afforded. That such medication is safe is not certain. For experiments in making and dispensing solutions of butyl-chloral hydrate, see *Proc. A. Ph. A.*, 1894, 578.

Dose, of British Pharmacopœia, from five to twenty grains (0.32 to 1.3 Gm.).

CAFFEINA. U. S., Br.

CAFFEINE [Theine]

(câf-fē-ī'nă)

"A feebly basic substance [$\text{C}_8\text{H}(\text{CH}_3)_3\text{N}_4\text{O}_2 + \text{H}_2\text{O}$] obtained from the dried leaves of *Thea sinensis* Linné (Fam. *Ternstræmiaceæ*), or from the dried seeds of *Coffea arabica* Linné (Fam. *Rubiaceæ*); found also in other plants."¹ *U. S.* "An alkaloid, $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{H}_2\text{O}$, usually obtained from the dried leaves of *Camellia thea*, *Link*, or the dried seeds of *Coffea arabica*, *Linn*. Crystallized from aqueous solution, it contains one molecule of water." *Br.*

Trimethyl-xanthine, Methyl-theobromine; Caffeia, Theina, Guaranina, Caféine, *Fr. Od.*; Coffeinum, *P. G.*; Koffein, Kaffein, Thein, *G.*; Caffeina, *It.*; Caffeina, *Sp.*

Caffeine (*Caffeia*) was first discovered by Runge, and afterwards by Pelletier, Caventou and Robiquet. Strecker first proved it

¹ The United States Pharmacopœia allows caffeine to be prepared from either one of the ordinary commercial sources, but because tea leaves contain a much larger percentage of the alkaloid than does the coffee berry, and are frequently thrown into commerce in a damaged condition, unfit for use as a beverage, commercial caffeine is almost always prepared from them. If the assertion of Thomas J. Mays, that theine, though chemically identical with caffeine, is physiologically different, be confirmed, it will become necessary to recognize theine as an official alkaloid, and direct that caffeine be prepared from coffee. The argument that tea and coffee differ in their gross effects on the human body, and that therefore the alkaloids cannot be identical, has no force, because coffee contains an active empyreumatic oil, developed during the process of roasting. How far the conclusions arrived at by Mays by experiments upon frogs must be accepted still remains a matter of opinion. We think, however, that further physiological studies of the three alkaloids theine, caffeine, and guaranine are necessary before their physiological diversity can be considered established. Dunstan and Shephard (*J. Chem. S.*, 1893, 195) reviewed the question of the identity of caffeine and theine with great care, and established the complete chemical identity of the two by a study of a number of derivatives. The clinical results obtained by Mays (*Med. News*, vol. xlviii.) are sufficient to warrant the trial of theine as a local anæsthetic injected in a dose of a third of a grain over painful nerves.

to be methyl-theobromine by making it from theobromine synthetically.² (*Ann. Ch. Ph.*, 118, 170.) It is now recognized as an immediate derivative of xanthine, $\text{C}_8\text{H}_4\text{N}_4\text{O}_2$ being the trimethyl-derivative of the same, and it belongs to the purine group, of which xanthine is the dioxy-derivative. Emil Fischer has accomplished the conversion of uric acid, $\text{C}_5\text{H}_4\text{N}_4\text{O}_6$, into xanthine, and this into caffeine.

Caffeine may be made as follows: Exhaust bruised coffee by two successive portions of boiling water, unite the infusions, add lead acetate in order to precipitate various principles accompanying the caffeine, filter, decompose the excess of lead acetate in the filtered liquor by hydrogen sulphide, concentrate by evaporation, and neutralize with ammonia. The caffeine is deposited in crystals upon cooling, and may be purified by redissolving in water, treating with animal charcoal, and evaporating. H. Leuchsenring obtains caffeine by availing himself of its property of subliming unchanged by heat. He precipitates a concentrated decoction of coffee by a weak solution of lead acetate, filters, evaporates to dryness, mixes the residue with sand, and sublimes as in Mohr's process for procuring benzoic acid. (*A. J. P.*, xxxii. 25.) Still another method, proposed by Vogel, is to treat coffee, ground to powder, with petroleum benzin, which dissolves the caffeine and an oily substance, separate the petroleum benzin by distillation and treat the residue with boiling water, which dissolves the caffeine, and deposits it in a crystalline form, after filtration and concentration. (*J. P. C.*, 3e sér., xxxv. 436.) Paul and Cowley's process for estimating the caffeine in coffee is to mix finely powdered coffee with moist lime, and exhaust with alcohol by hot reprecipitation. The alcohol is evaporated off, and the residue mixed with water and a few drops of diluted sulphuric acid; the mixture is filtered, and the filtrate and washings, when cool, treated with chloroform to wash out the alkaloid; the chloroformic solution is evaporated in a tared dish, and the residue weighed as caffeine. (*P. J.*, 1887, p. 565.) Petit and Terrat subsequently found that the presence of lime or magnesia retards the extraction of the caffeine, they recommend direct extraction by chloroform containing a trace of water (*J. P. C.*, 1896, 529). For another method, by E. D.

² In an examination of 25 varieties of coffee, Dragendorff found a variation in the amount of caffeine of from 0.6 to 2.2 per cent. The most important varieties were as follows:

Brown Penang	0.71	per cent.
Finest Mocha	0.64	"
Yellow Menado	1.22	"
Finest plantation Jamaica	1.43	"
First Surinam	1.78	"
Pearl plantation Ceylon	0.78	"
Yellow Java	0.88	"
Gray Java	2.21	"
First native Ceylon	0.87	"
Second " "	1.54	"
Third " "	1.59	"
Costa Rica	1.18	"
West Indian	1.22	"
Rio	1.14	"
Jamaica	0.67	"
Santos	1.46	"

Smith, see *Ph. Era*, 1887, 17; see also *A. J. P.*, 1892, 468, and 1893, 338; *J. P. C.*, 1893, 545; *Ap. Ztg.*, 1893, 132; *C. D.*, 1893, 210; *Ph. Era*, 1897, 391.

Caffeine is prepared on a considerable scale from damaged tea. The tea is exhausted with boiling water, the decoction boiled with litharge or lead acetate, and the filtered solution evaporated till the alkaloid crystallizes out on cooling. The product can be purified by resublimation or by crystallization from hot water. (Allen, *Com. Org. Anal.*, 2d ed., vol. iii., part ii., 474.)

Properties.—Caffeine is a feeble base, capable of forming definite compounds with mineral acids but not with organic acids; the latter, however, increase its solubility in water and other liquids. (See *Caffeina Citrata*.) Caffeine is in "white, flexible, silky, glistening needles, usually matted together in fleecy masses, permanent in the air; odorless, and having a bitter taste. If crystallized from water, it contains one molecule of water of crystallization, but if crystallized from alcohol, chloroform, or ether, it contains none. Soluble in 45.6 parts of water, 53.2 parts of alcohol, 375 parts of ether, and 8 parts of chloroform at 25° C. (77° F.); soluble in 5.2 parts of water at 80° C. (176° F.), and in 17.1 parts of alcohol at 60° C. (140° F.). Its solubility in water is increased by the presence of certain salts,—e.g., potassium bromide, sodium benzoate, sodium salicylate, and others. Caffeine sublimes at about 178° C. (352.4° F.), and should leave no residue. Its melting point is 236.8° C. (458.3° F.). An aqueous solution of Caffeine is neutral to litmus paper. If a small quantity of Caffeine be dissolved in about 1 Cc. of hydrochloric acid in a porcelain dish, a little potassium chlorate added, the whole evaporated to dryness on a water-bath, and the dish then inverted over a vessel containing a few drops of ammonia water, the residue will acquire a rich purple color, which is destroyed by fixed alkalies. If a fragment of Caffeine be dissolved in sulphuric acid and a minute fragment of potassium dichromate be added to the liquid, a yellowish-green color, which gradually becomes green, will be produced. Caffeine should dissolve in sulphuric acid or in nitric acid without producing a color (absence of *organic impurities*). Its aqueous solution should not be precipitated by mercuric potassium iodide T.S. (absence of *alkaloids*)." *U. S.* The British Pharmacopœia describes it as "soluble in 80 parts of cold water, the solution having a faintly bitter taste and being neutral to litmus. Easily soluble in boiling water, alcohol (90 per cent.), or chloroform; sparingly soluble in ether. It dissolves without color in sulphuric and nitric acids. At 212° F. (100° C.) the crystals lose 8.49 per cent. of their weight, and at a higher temperature melt and volatilize without decomposition. Treated with a crystal of potassium chlorate and a few drops of hydrochloric acid, and the mixture evaporated to dryness in a porcelain dish, a reddish residue results, which

becomes purple when moistened with solution of ammonia. In an aqueous solution of the alkaloid, tannic acid gives a white precipitate soluble in excess of the reagent, but no precipitate is caused by solution of potassium iodide containing mercuric iodide (distinction from other official alkaloids)." *Br.*

When the solution, made by saturating potassium iodide with mercuric oxide, is added to a solution of caffeine, a precipitate is produced, which soon takes the form of white, shining, acicular crystals. This reaction was proposed as a test of caffeine by Dellfs; for though the same solution will precipitate the other alkaloids, the product is always amorphous. (*Chem. Gaz.*, Feb. 45, 1855.) Tanret proposes to increase the solubility of caffeine by adding definite proportions of sodium benzoate, cinnamate or salicylate, which form with it compounds rich in alkaloid (45.8, 58.9, and 61 per cent. respectively). These are well adapted for hypodermic administration, as they are all freely soluble in water. The proportions recommended are as follows: caffeine-sodium benzoate (caffeine, 244, sodium benzoate, 288); caffeine-sodium cinnamate (caffeine, 244, sodium cinnamate, 170); caffeine-sodium salicylate (caffeine, 244, sodium salicylate, 160). (*L'Union Pharm.*, xxxvii, 394.) Caffeine is remarkable for containing a larger proportion of nitrogen than does almost any other proximate vegetable principle, in this respect equalling some of the highly animalized products.

Uses.—There have been a few cases of poisoning by caffeine; a drachm of citrated caffeine swallowed by an adult was followed by burning in the throat, giddiness, faintness, nausea, tremor of the extremities, abdominal pain, mental distress, great cardiac oppression and finally collapse. Consciousness was not impaired and there was no headache until the patient began to recover. A decoction of 8 ounces of freshly roasted coffee, taken for the purpose of producing abortion, caused pronounced choreic tremors, great restlessness, quickened respiration, and rapid pulse, with very strong, even violent, heart beats. In doses of 3 to 5 grains caffeine produces in the healthy individual a peculiar wakefulness, with stimulation of the cerebrum, and some increase of the urinary secretion and force of the pulse. There is usually marked increase of the mental activity and of the capability for sustaining mental work. About two hours after the ingestion of 12 grains by Pratt, there were intense physical restlessness and mental anxiety, with obstinate sleeplessness, active and persistent thinking, general muscular tremulousness, and frequent urination.

Given in large dose to the lower animals, caffeine produces hurried respiration, restlessness, slightly lowered, followed by markedly elevated, temperature, tetanic and clonic convulsions, progressive paralysis, and finally death from paralytic arrest of respiration. The cause of the convulsions in mammals is not determined, but in the frog they are of spinal origin, for

both Pratt and Le Blond have found that cutting of the cord does not arrest them below the point of section, while destruction of the cord (Pratt and Leven) prevents their development. It would appear, therefore, that caffeine acts upon the frog as a stimulant to the motor side of the spinal cord, and it is probable that the physical restlessness and tremulousness produced in man are largely of spinal origin. Upon the motor nerves caffeine has no effect, but there is some reason for suspecting that it exerts a very feeble influence upon the sensory nerves. Upon the muscles caffeine acts as a powerful poison; when an isolated piece of the gastrocnemius of the frog is thrown into a one per cent., or even weaker, solution of the citrate of caffeine, it becomes contracted and stiff, and unable to respond to the galvanic current in from two to three minutes. It has been abundantly proved that it is the muscle fibre which is affected, and it seems to be established that the paralysis is preceded by a period of excitement, during which the contractility of the muscle is increased both in its sensitiveness to stimuli and in its power. The action of caffeine upon the circulation is distinct, as has been shown by Leven, Binz, and other observers. The alkaloid produces in the mammal, elevation of the arterial pressure, which is at least in part due to a direct action upon the heart; caffeine in small dose reinforces the isolated frog's heart, and gives to its contractions more amplitude and more energy. Reichert found that even after destruction of the vasomotor centres in the medulla oblongata, caffeine still elevates the arterial pressure. He believes that this rise of the arterial pressure, which must be independent of the vasomotor centres, is due to a direct action of the caffeine upon the muscle fibres in the vessel walls. Direct proof of this, however, seems to be wanting, and it remains uncertain whether the rise of pressure is due entirely or only in part to the cardiac stimulation. In advanced stages of caffeine poisoning the arterial pressure falls, both the heart and the vasomotor system being depressed or paralyzed. The pulse rate is usually but not always increased by caffeine, probably due to a stimulation of the cardio-accelerator mechanism.

One of the most constant symptoms produced in man by overdoses of caffeine is excessive diuresis, and experiments made upon the lower animals show that caffeine acts as a diuretic not only by influencing the circulation, but also by directly affecting the secreting cells of the kidney or the nerves which dominate those cells, the probabilities being in favor of the first of these theories of action. According to Schroeder, not only the water but also the solids of the urine are increased.

The question whether caffeine has an influence upon tissue changes and the consequent nitrogenous elimination cannot be considered as distinctly answered, though the most probable conclusion is that the action of caffeine upon urea

elimination and upon general nutrition is not direct or pronounced. While the therapeutic dose of caffeine is broken up in the body with the formation of methyl-xanthine, which escapes with the urine, the toxic dose is at least in part eliminated by the kidney unchanged.

Caffeine is a valuable remedy in practical medicine as a cerebral and cardiac stimulant and as a diuretic. In undue *somnolence*, in *nervous headache*, in *narcotism*, also, at times, when the exigencies of life require excessively prolonged wakefulness, caffeine may be used as the most powerful agent known for producing wakefulness. In a series of experiments, J. Hughes Bennett found that within narrow limits there is a direct physiological antagonism between caffeine and morphine. Coffee and caffeine in narcotic poisoning are of value as a means of keeping the patient awake, and of stimulating the respiratory centres.

As a cardiac stimulant, caffeine may be used in any form of *heart failure*; the indications for its use are those which call for the employment of digitalis. It is superior to digitalis in never disagreeing with the stomach, in having no distinctive cumulative tendency, and in the promptness of its action. It is pronouncedly inferior to digitalis in the power and certainty of its action, and in the permanence of its influence once asserted. As a diuretic it is superior; it is very valuable in the treatment of *cardiac dropsies*, and is often useful in *chronic Bright's disease* when there is no irritation of the kidneys.

On account of its tendency to produce wakefulness, it is usually better to mass the doses early in the day, at least six hours being left between the last dose and the ordinary time for sleep. From eight to fifteen grains may be given in the course of a day in severe cases. If tried, it would probably prove a useful drug in cases of *sudden collapse* from various causes. The ordinary compounds of it are, however, not available for hypodermic use, because they are decomposed in the presence of water. The double benzoate of sodium and caffeine has been proposed as moderately stable and free from irritant properties: the following formula has also been commended by Tanret for hypodermic use: sodium salicylate, 31 gr.; caffeine, 40 gr.; distilled water, 60 gr. For internal administration the soluble preparation known as citrated caffeine is usually preferred.

Dose, one to five grains (0.065 to 0.32 Gm.).

CAFFEINA CITRATA. U. S. (Br.)

CITRATED CAFFEINE [Caffeine Citrate]

(cāf-fē-ī'na cī-trā'tā)

"An unstable compound, $C_8H_{10}N_4O_8$, $C_6H_8O_7$, prepared from Caffeine and Citric Acid." Br.

Caffeina Citras, Br.; Citrate de Caffeine, Fr.; Koffeincitrat, Citronensaures Koffein, G.; Citrato cafeico, Sp.

* "Caffeine, *fifty grammes* [or 1 ounce av., 334 grains]; Citric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, hot, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Citric Acid in the hot Distilled Water, add the Caffeine, and evaporate the resulting solution, on a water-bath, to dryness, constantly stirring toward the end of the operation. Reduce the product to a fine powder and transfer it to well-stoppered bottles." *U. S.* "Caffeine, 1 ounce (Imperial) or 20 grammes; Citric Acid, 1 ounce (Imp.) or 20 grammes; Distilled Water, 2 fl. ounces (Imp. meas.) or 40 cubic centimetres. Dissolve the Citric Acid in the Distilled Water; stir the Caffeine into the heated solution; evaporate to dryness on a water-bath, constantly stirring towards the end of the operation; reduce to a fine powder." *Br.*

In this preparation Merson (*P. J.*, 1904, 8) prefers to mix the caffeine with the citric acid without the aid of a liquid; he uses a sieve, water bath, and granulating tray, and asserts that the process yields a superior product. It is not regarded by chemists as a chemical salt, but as a mechanical mixture of the two substances composing it. The British Pharmacopœia gives the following as its chemical formula: $C_8H_{10}N_4O_2, C_6H_8O_7$.

It is described by the U. S. Pharm. as "a white powder, odorless, having a slightly bitter, acid taste and an acid reaction. One part of Citrated Caffeine forms a clear, syrupy solution, with about 4 parts of hot water. Upon dilution with 5 parts of water, a white, crystalline precipitate (caffeine) separates, which redissolves when about 25 parts of water have been added. It is also soluble in a mixture of equal volumes of chloroform and alcohol. If 0.25 Gm. of Citrated Caffeine be mixed with 5 Cc. of concentrated sulphuric acid in a porcelain dish, the mixture protected from dust and heated for fifteen minutes on a water-bath, a lemon-yellow color, and not a brown or black color, should develop (absence of tartaric acid)." *U. S.* The British Pharm. describes it as "a white inodorous powder with an acid and faintly bitter taste and an acid reaction on litmus. It is soluble in 32 parts of water, and also in a mixture of 2 parts of chloroform with one part of alcohol (90 per cent.). With 3 parts of water it forms a clear syrupy solution, but more water dissociates the salt and affords a white precipitate of caffeine which redissolves when excess of water is added. Heated in the air, the salt is charred and then burnt, leaving a mere trace of ash. It affords the reactions mentioned under 'Caffeina,' and also those characteristic of citrates." *Br.*

Uses.—Citrated caffeine is possessed of the physiological and therapeutic properties of caffeine.

Dose, from three to eight grains (0.2 to 0.5 Gm.).

Off. Prep.—Caffeina Citrata Effervescens, *U. S.* (*Br.*).

CAFFEINA CITRATA EFFERVESCENS.

U. S. (*Br.*)

EFFERVESCENT CITRATED CAFFEINE

(căf-fē-tīnă cĭ-tră'tă ēf-fēr-vēs'cens)

Caffeina Citras Effervescens, Br.; Effervescent Caffeine Citrate; Coffeinum Citricum Effervescens; Brausendes Koffeintrat, *G.*

* "Citrated Caffeine, *forty grammes* [or 1 ounce av., 180 grains]; Sodium Bicarbonate, dried and powdered, *five hundred and seventy grammes* [20 ounces av., 46 grains]; Tartaric Acid, dried and powdered, *three hundred grammes* [or 10 ounces av., 255 grains]; Citric Acid, uneffloresced crystals, *one hundred and ninety-five grammes* [or 6 ounces av., 384 grains], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Powder the Citric Acid and mix it intimately with the Citrated Caffeine and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles." *U. S.*

"Sodium Bicarbonate, in powder, 51 ounces (Imperial) or 510 grammes; Tartaric Acid, in powder, 27 ounces (Imp.) or 270 grammes; Citric Acid, in powder, 18 ounces (Imp.) or 180 grammes; Refined Sugar, in powder, 14 ounces (Imp.) or 140 grammes; Caffeine Citrate, 4 ounces (Imp.) or 40 grammes. Mix the Caffeine Citrate, Tartaric Acid, and Citric Acid; with this product thoroughly incorporate the mixed Sodium Bicarbonate and Refined Sugar; place in a dish or pan of suitable form heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (or 1000 grammes)." *Br.*

This compound contains about two per cent. of caffeine; the proportion was about one per cent. in the U. S. P. 1890. The old expensive process in which alcohol was used to make the mass, was abandoned, the amount of water of crystallization liberated from the citric acid on decomposition proving sufficient to moisten the mass; this effects a saving in the expense of manufacturing, while the use of heat with skilful manipulation has been found to produce equally good results. It differs from that of the British Pharmacopœia in containing no sugar. Samples of effervescent citrated caffeine have been found in the market very deficient in caffeine; the sweetening is some-

times effected by the use of saccharin instead of sugar. The powder affords an agreeable method of administering citrated caffeine.

Dose, one teaspoonful (3.9 Gm.) in water, to be taken during effervescence.

CALAMUS. U. S.

"The unpeeled, dried rhizome of *Acorus Calamus* Linné (Fam. *Araceæ*)." U. S.

Radix Calami Aromatici, Radix Acori; Sweet Sedge (Cane, Rush, Root or Myrtle), Myrtle-flag (Grass or Sedge); Acore Vrai, Fr. *Cod.*; Acore Odorant, Fr.; Rhizoma Calami, P. G.; Kalmus, Kalmuswurzel, G.; Calamo aromatico, It., Sp.

Acorus Calamus, Willd., *Sp. Plant.* ii. 199; Barton, *Med. Bot.*, ii. 63; B. & T. 279.—The sweet flag, or calamus, has a perennial, horizontal, jointed, somewhat compressed root (rhizome), from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish radicles from its base, and bunches of brown fibres resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular stains of light brown and rose color. The leaves are all radical, sheathing at the base, long, sword-shaped, smooth, green above, but, near their origin from the root, of a red color, variegated with green and white. The scape or flower stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. The fruit is an oblong capsule, divided into three cells, and containing numerous oval seeds.

This plant, which grows abundantly in the wet places throughout the United States, is very widespread in its world distribution, being found in Europe, Western and Southern Asia, including India and Japan, so that the dried rhizomes of commerce are produced in the three continents. The leaves as well as the root have an aromatic odor; but the root only is employed. It should be collected late in the autumn, or in the spring. After removal from the ground, the rhizomes are washed, freed from their fibres, and dried with a moderate heat. By drying they lose nearly one-half their diameter, but are improved in odor and taste.¹

Properties.—Calamus is officially described as follows: "Rhizome 1 to 2 Cm. thick, usually in longitudinally split pieces of various lengths; when entire, cylindrical and somewhat vertically flattened, externally reddish-brown, some-

what annulate from remnants of leaf-sheaths; upper surface with triangular leaf-scars, the lower surface with circular pitted scars of roots; fracture short, showing numerous oil-cells and scattered fibrovascular bundles, the latter crowded within the endodermis; odor aromatic; taste pungent and bitter." U. S. Their texture is light and spongy, their color internally whitish or yellowish white, and their fracture short and rough. A German variety imported consists solely of the interior of the root. The pieces are usually long, slender, irregularly quadrangular, and of grayish-white color.

The odor of calamus is strong and fragrant; its taste warm, bitterish, pungent, and aromatic. Its active principles are taken up by boiling water. From 100 parts of the fresh root of the European plant, Trommsdorf obtained 0.1 of volatile oil, 2.3 of soft resin, 3.3 of extractive with a little potassium chloride, 5.5 of gum with some potassium phosphate, 1.6 of starch analogous to inulin, 21.5 of lignin, and 65.7 of water.² Sixteen ounces of the dried root afforded to Neumann about two scruples of volatile oil. The oil is at first yellow, but ultimately becomes red, and has the odor and taste of calamus. Kurbatow (*Ann. Ch. Ph.*, vol. 173, p. 4) examined oil of calamus, and found that the portion boiling below 170° C. (338° F.) yielded after treatment with sodium a terpene, C₁₀H₁₆, having a sp. gr. .8793 at 0° C. (32° F.), and having a boiling point of 158° C. (316.4° F.). According to Schimmel's Report (April, 1895), all oils of calamus having a lower rotary power than +10° and those which do not yield clear solutions with any proportion of 90 per cent. alcohol should be rejected. The extractive matter has an acrid and sweetish taste. H. Thomas obtained from calamus rhizomes a bitter principle, which he named *acarin*, in the form of a clear, thick, yellow liquid, having a neutral reaction, aromatic odor, and bitter, aromatic taste. It is a glucoside, having the formula C₂₅H₄₀O₆, splitting into oil of calamus and sugar; insoluble in water, but readily soluble in absolute alcohol, methyle alcohol and chloroform. By oxidation *acoretin*, a neutral resin is formed, and from the extract remaining after the *acarin* is removed Thomas obtained an alkaloid which he named *calamine*; this is crystalline, insoluble in water and ether, but soluble in alcohol, chloroform, and acetone. (*A. Pharm.*, 1886, 465; *P. J.*, 1886, 1085.) Calamus is sometimes attacked by worms, and deteriorates by keeping. The India variety is more slender than the European, and has a stronger and more pleasant flavor.

Uses.—Calamus is a feeble aromatic and as such is used, especially in domestic practice, in India and to some extent in other portions of the world. It is said to have been employed also by the Greeks under the name of ἀκόρος,

¹ There has been a belief that calamus was known to the ancient Babylonians, this belief being founded on the translation of the word "qantū," occurring in the old Babylonian tablets, as "calamus." Albert G. Clay of the University of Pennsylvania, however, informs us that the word "qantū" means simply, so far as is at present known, "reeds," so that the passage usually translated "into their bowels I poured calamus, cedar, fragrant herbs" should be rendered "into their bowels I poured reeds, cedar, fragrant herbs."

² The volatile oil is contained in all portions of the plant, the leaves yielding to distillation, according to the analysis of Schimmel & Co. 0.2 per cent., the fresh root 1.5 to 3.5 per cent. the dried German root 0.8 and the Japan root as much as 5 per cent.

but not to be the *calamus aromaticus* of Dioscorides, which is affirmed by Royle to have been derived from *Andropogon*. The volatile oil is largely used in perfumery, and the powdered root itself is esteemed in Ceylon and India as a vermifuge and an insecticide.

Dose, in substance, 20 to 60 grains (1.3 to 3.9 Gm.); of infusion (an ounce to one pint of boiling water), one to two wineglassfuls (60 to 120 Cc.).

Off. Prep.—Fluidextractum Calami, *U. S.*

CALCII BROMIDUM. *U. S.*

CALCIUM BROMIDE

(cāl'cī-i brō'mj-dūm)

$\text{CaBr}_2 = 198.52$

"It should contain not less than 97 percent. of pure Calcium Bromide, and should be kept in well-stoppered bottles." *U. S.*

Calcium Bromatum, Bromure de Calcium, Bromure de Chaux, *Fr.*; Brom Kalk, Calcumbromid, *G.*

The process of Boedecker for its preparation consists in first forming a sulphur bromide, by the addition of 20 parts of the flowers of sulphur to 240 parts of bromine; this is added to a milk of lime containing 140 parts of fresh lime. Calcium bromide and sulphate are formed and are readily separated. (*J. P. C.*, 4e sér., viii. 463.) By the process of Jas. R. Mercier, five ounces of bromine and two and a half pints of water are put in a half-gallon specie jar, a stream of hydrogen sulphide passed through the bromine until it is all taken up, the liquid filtered, excess of hydrogen sulphide driven off by heat, and the solution of hydrobromic acid thus obtained distilled until four-fifths have passed over; the distillate is saturated with excess of precipitated calcium carbonate, filtered, and evaporated. (*A. J. P.*, xlv. 100.) Macdonald's method (*A. J. P.*, 1873), is as follows. Dissolve 4 ounces of ammonium bromide in a pint of water. Put into a flask and bring to the boiling point. Keep boiling, and add milk of lime (made from pure calcined lime) in small quantities, until ammoniacal vapors cease to be evolved. The operator can easily tell when this point has been reached, by the sense of smell. Filter the solution, evaporate to a syrupy consistency, remove from the fire, and stir until cold. Tasilly prepares calcium oxybromide by adding three parts of calcium oxide in small portions to a solution of one hundred parts of calcium bromide in seventy-five parts of hot water; acicular crystals of calcium oxybromide, $\text{CaBr}_2 \cdot 3\text{CaO} \cdot 16\text{H}_2\text{O}$, are deposited on cooling the filtered solution.

Properties.—It is officially described as "a white, granular salt, odorless, of a sharp, saline taste, and very deliquescent. Soluble in 0.5 part of water, and in 1 part of alcohol at 25° C. (77° F.); more soluble at boiling temperatures. An aqueous solution of the salt is neutral to litmus paper. The aqueous solution of the salt (1 in 20) yields with ammonium oxalate

T.S. a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. Silver nitrate T.S. produces a light yellow precipitate, insoluble in nitric acid and in moderate excess of ammonia water." *U. S.*

Tests.—"If to 10 Cc. of the aqueous solution of the salt (1 in 20), 1 Cc. of chloroform be added, then chlorine water, which has been diluted with an equal volume of water, added cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color free from any violet tint (absence of iodides). If 1 Gm. of Calcium Bromide be added to 20 Cc. of water, it should form a clear, colorless solution, leaving no residue (absence of insoluble impurities). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). If 1 Gm. of Calcium Bromide and 1 Gm. of sodium acetate be dissolved in 5 Cc. of distilled water, and the solution made slightly acid through the addition of from 3 to 5 drops (or a sufficient quantity) of diluted acetic acid, after boiling and thoroughly cooling, the solution should not become cloudy within five minutes upon the addition, with agitation, of 5 drops of potassium dichromate T.S. (absence of barium). If diluted sulphuric acid be dropped upon the salt, the latter should not at once assume a yellow color (absence of bromate). To 5 Cc. of an aqueous solution of the salt (1 in 100), contained in a test-tube of about 40 Cc. capacity, add 5 Cc. of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire. In the upper portion of the test-tube, insert a plug of purified cotton or gauze, and over the mouth, a piece of moistened red litmus paper; place the tube in a bath of boiling water, and after fifteen minutes no blue coloration of the paper should be discernible (limit of nitrates and ammonia)." *U. S.*

Uses.—Calcium bromide was proposed by Hammond, in 1871, as a substitute for the corresponding salt of potassium. It has failed to gain much support from the medical profession, but is sometimes employed as an adjuvant in *epilepsy* and *hysteria*. Its action upon the lower animals has been partially investigated by Guttman (*P. M. T.*, iv. 361), who finds that it is a sedative to the nerve centres, but lacks the depressant cardiac action of potassium bromide.

Dose, fifteen to thirty grains (1 to 2 Gm.).

CALCII CARBONAS PRÆCIPITATUS.

U. S., Br.

PRECIPITATED CALCIUM CARBONATE PRECIPITATED CHALK

(cāl'cī-i cār'bō-nās præ-ēp-i-tā'tūs)

$\text{CaCO}_3 = 99.35$

"It should contain not less than 99 percent. of pure Calcium Carbonate." *U. S.* "The

precipitate, CaCO_3 , obtained by the interaction of calcium chloride and sodium carbonate." *Br.*

Carbonas Calcicus Præcipitatus, Creta Præcipitata, Calcaria Carbonica Præcipita; Precipitated Carbonate of Lime; Carbonate de Chaux Précipité, *Fr. Cod.*; Craie Précipitée, *Fr.*; Calcium carbonicum præcipitatum, *P. G.*; Calciumcarbonat; Präcipitirter kohensaure Kalkerde, *G.*; Carbonato di calcio precipitato, *It.*; Carbonato de cal, *Sp.*

A formula for this salt is found in the Pharmacopœia of 1870. It is as follows: "Take of Solution of Chloride of Calcium five pints and a half; Carbonate of Sodium seventy-two troy-ounces; Distilled Water a sufficient quantity. Dissolve the Carbonate of Sodium in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper." *U. S.* 1870.

A mutual interchange of principles takes place, resulting in the production of sodium chloride which remains in solution, and calcium carbonate which is deposited,

Any peculiar advantage of the preparation must depend on the minute division of its particles. According to Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in most processes. (*A. J. P.*, xvi. 163.) When properly made, it is "a fine, white powder, without odor or taste, and permanent in the air. Nearly insoluble in water; the solubility is increased by the presence of ammonium salts, and especially by carbon dioxide; alkali hydroxides diminish its solubility; insoluble in alcohol; in diluted acetic, hydrochloric, or nitric acid, it is completely soluble with effervescence. When heated to full redness, with access of air, the salt gradually loses carbon dioxide, and a residue of calcium oxide remains. For applying tests of identity and of purity, 5 Gm. of Calcium Carbonate are mixed with 100 Cc. of distilled water, followed by hydrochloric acid, added drop by drop, with agitation, until solution takes place. The resulting solution should, after boiling and cooling, be of acid reaction, and there should not remain more than traces of insoluble matter. In a portion of this acid solution, after neutralizing with ammonia water, ammonium oxalate T.S. produces a white precipitate of calcium oxalate, insoluble in acetic acid but soluble in hydrochloric acid. If to 20 Cc. of the acid solution, ammonia water be added until of alkaline reaction, no turbidity or precipitation should take place either before or after boiling (absence of iron, aluminum, phosphates, etc.). The acid solution should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). If 1 Gm. of the salt be agitated with 50 Cc. of water, the filtrate

should not show an alkaline reaction with litmus paper, and, on evaporation, should not leave a weighable residue (limit of soluble impurities)." *U. S.*

Uses.—For ordinary purposes, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness, but it is preferred by some in the preparation of tooth powders.

Dose, from ten to forty grains (0.65 to 2.6 Gm.).

Off. Prep.—Pulvis Morphinae Compositus, *U. S.*; Syrupus Calcii Lactophosphatis, *U. S.*, *Br.*; Trochiscus Bismuthi Compositus, *Br.*

CALCII CHLORIDUM. U. S., Br.

CALCIUM CHLORIDE

(cāl'cl-i ghlō'rj-dūm)

$\text{CaCl}_2 = 110.16$

"Calcium Chloride, rendered anhydrous by fusion at the lowest possible temperature. It should contain not less than 99 percent. of pure Calcium Chloride, and should be kept in well-stoppered bottles." *U. S.* "The salt, $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, formed by neutralizing hydrochloric acid with calcium carbonate, carefully desiccated at a temperature not exceeding 392°F. (200°C.)." *Br.*

Calcium Chloratum; Calcaria Muriatica, Chloridum Calcicum; Muriate of Lime, Hydrochlorate of Lime; Chlorure de Calcium Fondu, Hydrochlorate de Chaux, *Fr.*; Chlorcalcium, Calciumchlorid, Salzsäures Kalk, *G.*; Cloruro di calcio, *It.*; Cloruro calcico, *Sp.*

Calcium chloride may be readily formed by saturating hydrochloric acid with chalk or marble, evaporating to dryness, and heating to redness. The hydrochloric acid, by reacting with the calcium carbonate, forms calcium chloride, carbon dioxide, and water, the latter of which is dissipated at a red heat,

The *Br. Ph.* (1885), after neutralizing the acid with calcium carbonate, adds a little solution of chlorinated lime and slaked lime, filters, evaporates until the chloride becomes solid, and, instead of igniting the residue, dries it at about 204.4°C. (400°F.). Its composition, according to the British Pharmacopœia, is $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$.

Properties.—Calcium chloride is in "white, slightly translucent, hard fragments, odorless, having a sharp, saline taste. It is very deliquescent. Soluble in 1.3 parts of water, and in 8 parts of alcohol at 25°C. (77°F.); in 1.5 parts of boiling alcohol, and very freely soluble in boiling water, usually leaving a slight residue. Below a red heat the salt fuses, and, on cooling, solidifies without change in composition. When perfectly pure, Calcium Chloride dissolves in water without residue; the solution should be strictly neutral to litmus paper. When the salt has been overheated in fusing, the solution has an alkaline reaction, and a small residue of calcium oxide is left, which is soluble in hy-

drochloric acid. The aqueous solution (1 in 20) yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. With silver nitrate T.S. it yields a white precipitate insoluble in nitric acid. If to the aqueous solution of the salt (1 in 20) ammonia water be added, until of alkaline reaction, no turbidity or precipitation should take place either before or after boiling (absence of *iron, aluminum, phosphates, etc.*). If from 10 Cc. of the solution the calcium be completely precipitated by ammonium oxalate T.S., the filtrate should, on evaporation and ignition, leave not more than a trace of fixed residue (limit of *magnesium and alkalies*). The aqueous solution of the salt (1 in 20), slightly acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic or lead* (see PART III, Test No. 121). *U. S.* "In dry, white, very deliquescent masses, soluble in an equal weight of water and in 3 parts of alcohol (90 per cent.). It affords the reactions characteristic of calcium and of chlorides. It should yield no characteristic reaction with the tests for iron, aluminium, or carbonates, and only the slightest reactions with the tests for magnesium. It evolves no chlorine or hypochlorous acid on the addition of hydrochloric acid (absence of hypochlorite)." *Br.* On account of its avidity for water, the fused salt is used for drying gases. The crystallized salt is also very deliquescent, and has the form of colorless, transparent, striated, six-sided prisms. The crystals, on exposure to heat, first dissolve in their water of crystallization, and, after this has evaporated, undergo igneous fusion. With ice or snow they form a powerful frigorific mixture. Calcium chloride exists in the water of the ocean and of many springs. It is usually associated with common salt and magnesium chloride, from which it is separated with difficulty. When crystallized it contains six molecules of water.

Uses.—Calcium chloride has the property of increasing the coagulability of the blood, and has been used to a considerable extent in *hæmophilia, hæmoptysis, menorrhagia*, and other forms of *internal bleeding*. Mayo Robson commends its administration for several days preceding surgical operations in which there is reason to expect severe hemorrhage. In severe cases of internal hemorrhage W. T. Silvestri reports excellent results from the intravenous injection of from three and one-half to five fluidounces (105 to 150 Cc.) of a recently sterilized one per cent. solution of the salt. The five per cent. solution has been frequently used in the form of an enema.

Dose, five grains (0.32 Gm.) three times a day, increased if necessary to twenty grains (1.3 Gm.), in dilute solution.¹

¹ *Liquor Calcii Chloridi* was official in the U. S. P. 1870. A convenient method of making this preparation is to dissolve 228 grains of fused calcium chloride in 1 fluidounce of distilled water, and filter if necessary.

CALCII HYDRAS. Br.

CALCIUM HYDROXIDE SLAKED LIME

(cāl'cī-i hŷ'drās)

"Calcium hydroxide, $\text{Ca}(\text{HO})_2$, recently prepared by the interaction of water and calcium oxide." *Br.*

Calcis Hydras; Hydrate of Lime; Chaux Eteinte, *Fr. Cod.*; Idrato di calcio, *It.*

The British Pharmacopœia no longer gives a detailed process for slaked lime. The process of the *Br. Pharm.* (1885) is as follows: "Take of Lime two pounds [avoirdupois]; Distilled Water one pint [Imperial measure]. Place the Lime in a metal pot, pour the water upon it, and when vapor ceases to be disengaged cover the pot with its lid and set it aside to cool. When the temperature has fallen to that of the atmosphere, put the slaked lime on an iron-wire sieve, and by gentle agitation cause the fine powder to pass through the sieve, rejecting what is left. Put the powder into a well-stoppered bottle, and keep it excluded as much as possible from the air. Slaked lime should be recently prepared." *Br.* 1885. Calcium hydroxide "affords the reactions characteristic of calcium. Strongly heated it loses nearly one fourth of its weight of water. It should yield only the slightest characteristic reactions with the tests for iron, aluminium, magnesium, sodium, potassium, carbonates, chlorides, phosphates, sulphates, or silica." *Br.*

For an account of the physical and medicinal properties of slaked lime, see *Calcx*.

CALCII HYPOPHOSPHIS. U. S., Br.

CALCIUM HYPOPHOSPHITE

(cāl'cī-i hŷ-pō-phōs'phīs)

$\text{Ca}(\text{PH}_2\text{O}_2)_2 = 168.86$

"It should contain not less than 98 percent. of pure Calcium Hypophosphite [$(\text{PO}.\text{OH})_2\text{Ca}$], and should be kept in well-stoppered bottles; caution should be observed in dispensing Calcium Hypophosphite, as explosion is liable to occur when it is triturated or heated with nitrates, chlorates, or other oxidizing agents." *U. S.* "Calcium Hypophosphite, $\text{Ca}(\text{PH}_2\text{O}_2)_2$, is obtained by the interaction of phosphorus, calcium hydroxide, and water." *Br.*

Calcis Hypophosphis; Calcium Hypophosphororum, Hypophosphite of Lime; Calcaria Hypophosphorosa, Hypophosphis Calcicus; Hypophosphite de Chaux, *Fr. Cod.*; Unterphosphorigsaure Kalkerde, Calcium hypophosphit, *G.*; Hipofosfito calcico, *Sp.*

Attention has been called to the hypophosphites as a class of salts, in consequence of their recommendation by Churchill of Paris, in the treatment of *phthisis*, in which they were thought to be useful by furnishing phosphorus

to the tissues. One of the first papers on their mode of preparation and qualities was communicated by Wm. Procter. (See *A. J. P.*, xxx. 118.) Hypophosphorous acid consists of one atom of phosphorus, two of oxygen, and three of hydrogen, of which latter, however, only one atom is replaceable by metal. It is, therefore, a monobasic acid. It has a strong affinity for oxygen, and acts as a powerful deoxidizing or reducing agent, which property it is supposed to owe to the presence of the unreplaceable hydrogen atoms, sometimes termed "aldehydic" hydrogen. When heated, it is resolved into hydrogen phosphide and phosphoric acid. Its salts are generally soluble in water and deliquescent, and many of them are soluble in alcohol. They are converted into phosphates by heat, with the escape of hydrogen phosphide, and some of them are explosive.

Calcium hypophosphite has been most largely employed, and meets the views of those who wish to supply calcium phosphate to the system, as the hypophosphorous acid is converted into the phosphoric by its deoxidizing power. To prepare it Procter gave the following formula. Slake 4 pounds (avoirdupois) of lime with a gallon of water, add it, in a deep boiler, to 4 gallons of boiling water, and mix thoroughly. To the mixture add a pound (av.) of phosphorus, and continue the boiling, adding hot water from time to time to keep up the measure, until the combination is complete, and hydrogen phosphide is no longer evolved. It is necessary that provision should be made for the escape of the gas, which takes fire spontaneously in contact with the air. There are formed in the liquid calcium phosphate and hypophosphite, the phosphorus having become oxidized at the expense of the water, the hydrogen of which has escaped in combination with another portion of phosphorus, which is therefore lost. The liquid is filtered to separate the insoluble phosphate and residuary lime, then concentrated, and re-filtered to separate the calcium carbonate formed by the action of the air on a little lime held in solution, and lastly evaporated until a pellicle appears; after which the salt may be allowed to crystallize by setting the liquid aside, or may be obtained in the granular form by continuing the heat, and stirring. The salt should be introduced into bottles. The former British Pharmacopœia practically adopted this process, but any uncombined lime remaining in the solution was separated by passing carbonic acid gas through it.

Properties.—Officially described as in "colorless, transparent, monoclinic prisms, or small, lustrous scales, or a white, crystalline powder, odorless, having a nauseous and bitter taste; permanent in the air. Soluble in 6.5 parts of water at 25° C. (77° F.), and in 6 parts of boiling water; insoluble in alcohol. When heated in a test-tube the salt decrepitates, and above 300° C. (572° F.) it begins to decompose, giving off water, and emitting inflam-

mable gases (hydrogen and hydrogen phosphide), and leaving a residue of calcium pyrophosphate and metaphosphate, with some red phosphorus. The aqueous solution (1 in 20) is neutral or slightly acid to litmus paper, and yields, with ammonium oxalate T.S., a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. The diluted aqueous solution, slightly acidulated with diluted nitric acid, yields with silver nitrate T.S. a precipitate, which is white at first but rapidly turns brown and black, due to the separation of metallic silver. With copper sulphate T.S., on gentle heating, a reddish-brown precipitate is formed. When the aqueous solution of Calcium Hypophosphite (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, with agitation, to an excess of mercuric chloride T.S., a white precipitate of mercurous chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray in color, due to its reduction to metallic mercury. If 1 Gm. of the salt be added to 20 Cc. of water and well shaken, not more than a trace of residue should remain (absence of *phosphate* and *sulphate*). If 5 Cc. of an aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water, and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121)." *U. S.* "Soluble in 8 parts of cold water; insoluble in cold alcohol (90 per cent.). Heated to redness the crystals ignite, evolving spontaneously inflammable hydrogen phosphide and hydrogen, and leave a reddish-colored residue. It affords the reactions characteristic of calcium. Its aqueous solution yields with *test-solution of mercuric chloride* a white precipitate turning gray. 0.25 gramme boiled for ten minutes with a solution of 0.6 gramme of *potassium permanganate* should yield, on filtration, a nearly colorless solution. The salt should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, magnesium, sodium, or potassium, and only the slightest reactions with the tests for chlorides or sulphates. It should afford little or no precipitate with *solution of lead acetate* (limit of phosphates and phosphites)." *Br.* The solubility of calcium hypophosphite is increased by the addition of hypophosphorous acid. For a method of purifying alkaline hypophosphites, see *J. P. A.*, 1879, 57; *N. R.*, 1879, 142.

As the soluble salts of mercury, copper, and silver are reduced by the hypophosphites, they are of course incompatible with it in prescriptions. With calcium hypophosphite all the soluble sulphates and carbonates produce precipitates. As the hypophosphites are insoluble in cod liver oil, they should be dissolved in syrup or water before being added to the oil. (See

Syrupus Hypophosphitum and *Emulsum Olei Morrhue cum Hypophosphitibus*.) W. A. H. Naylor considers the presence of sulphites in commercial hypophosphites to be the source of the disagreeable odor of hydrogen sulphide sometimes found in the compound syrup of hypophosphites. (*P. J.*, 1895, 144.)

Uses.—Calcium hypophosphite was at one time largely used in *chronic phthisis*, in various *scrofulous affections*, in *neurasthenia*, and other conditions of impaired nutrition of the nerve centres. It seems in none of these cases to be really efficient, but is harmless.

Dose, ten to thirty grains (0.65 to 2.0 Gm.), three times a day. (See *Syrupus Hypophosphitum* and *Syrupus Hypophosphitum Compositus*.)

Off. Prep.—*Emulsum Olei Morrhue cum Hypophosphitibus*, *U. S.*; *Syrupus Hypophosphitum*, *U. S.*; *Syrupus Hypophosphitum Compositus*, *U. S.*

CALCII PHOSPHAS PRÆCIPITATUS.

U. S. (Br.)

PRECIPITATED CALCIUM PHOSPHATE

(cāl'ci-i phōs'phās præ-cip-i-tā'tūs)

$\text{Ca}_3(\text{PO}_4)_2 = 307.98$

"It should contain not less than 99 percent. of pure Calcium Phosphate $[(\text{PO}_4)_2\text{Ca}]$." *U. S.* "Calcium Phosphate may be prepared by dissolving bone ash in dilute hydrochloric acid, adding the liquid to dilute solution of ammonia, washing the precipitate with cold water, and drying the washed precipitate at a temperature not exceeding 212°F . (100°C .); or by the interaction of calcium chloride and sodium phosphate." *Br.*

Calcii Phosphas, *Br.* **Calcis Phosphas** (*Br.* 1885), Calcium Phosphate; Tricalcium Phosphate, Calcaria Phosphorica; Phosphas Calcicus Præcipitatus; Precipitated Phosphate of Lime; Phosphate of Calcium; Phosphate Tricalcique, *Fr. Cod.*; Phosphate de Chaux hydraté, *Fr.*; Phosphorsäure Kalkerde, Calciumphosphat, *G.*; Fosfato calcico, *Sp.*

A formula for this precipitate was given in the *U. S. Pharmacopœia* of 1870. It is as follows: "Take of Bone, calcined to whiteness, and in fine powder, *four troyounces*; Muriatic Acid *eight troyounces*; Water of Ammonia *twelve fluidounces*, or a sufficient quantity; Distilled Water a sufficient quantity. Macerate the Bone in the Acid, diluted with a pint of Distilled Water, until it is dissolved, and filter the solution. Add another pint of Distilled Water, and then, gradually, Water of Ammonia, until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling Distilled Water, and pour the whole upon a strainer. Wash the precipitate with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly, dry the precipitate with a gentle heat." *U. S.* 1870. For description of an apparatus for preparing calcium phosphate on a large scale, see *J. P. C.*, Sept. 1, 1875, 193. The salt has been very properly retained in the

U. S. and *Br. Pharmacopœias*. There is, however, no necessity of retaining the word "præcipitatus" in the *U. S.* title, as it is never seen in commerce except as a precipitate. One of its uses has been to replace magnesium carbonate and absorbent cotton in the 1890 process for medicated waters; but it has now been superseded by purified tale.

The hydrochloric acid dissolves the calcium phosphate of the bones, and lets it fall, on the addition of ammonia, in a state of minute division. The ablation is intended to free it from adhering ammonium chloride. The salt thus obtained is, for the sake of distinction, called *bone calcium phosphate*.

Properties.—It is officially described as "a bulky, white, amorphous powder, odorless and tasteless; permanent in the air. Almost insoluble in cold water; partly decomposed by boiling water, which dissolves out the acid salt; almost insoluble in acetic acid, except when freshly precipitated; easily soluble in hydrochloric or nitric acid; insoluble in alcohol. At an intense white heat, the salt fuses without decomposition. When moistened with silver nitrate T.S., either before or after ignition, the salt acquires a yellow color (distinction from *acid calcium phosphate*, which, after ignition, when moistened with silver nitrate T.S., remains white). For applying tests of identity and of purity, shake 2 Gm. of Precipitated Calcium Phosphate with 20 Cc. of water, add nitric acid, drop by drop, until solution is effected, and then add sufficient water to make the liquid measure 40 Cc. While making this solution, no effervescence should occur on adding the acid (absence of carbonate). From a portion of this solution the salt is precipitated unchanged by a slight excess of ammonia water. From another portion ammonium molybdate T.S. precipitates yellow ammonium phosphomolybdate; the reaction is accelerated by a gentle heat, not exceeding 65°C . (149°F .). If to 5 Cc. of the solution, acidulated with nitric acid, 0.5 Cc. of silver nitrate T.S. be added, not more than a slight turbidity should result (limit of *chloride*). If to 5 Cc. of the solution, strongly acidulated with nitric acid, 1 Cc. of potassium sulphate T.S. be added, no turbidity should result upon standing (absence of *barium*). An aqueous solution of Calcium Phosphate (1 in 20), obtained by shaking the salt with water, adding hydrochloric acid, drop by drop, and heating until solution is effected, should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Two Gm. of Calcium Phosphate should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." *U. S.* "Soluble in *diluted hydrochloric acid* or *diluted nitric acid*; such a solution continues clear when a dilute solution of *sodium acetate* is added in excess (absence of calcium oxalate). It affords the reactions characteristic of calcium and of phosphates. Of the recently dried powder, 1 gramme dissolved in *diluted hydrochloric acid*

yields, when added to a very slight excess of diluted solution of ammonia, a white precipitate weighing when washed with cold water and dried at 212° F. (100° C.) not less than 0.95 gramme. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, magnesium, carbonates, or silica, and only the slightest reactions with those for chlorides." *Br. Joly and Sorel* record (*C. R. A. S.*, 1894, 738) the precipitation of tricalcium phosphate by adding crystals of hydrated bicalcium phosphate to boiling water; the acid liquid remaining contains monocalcium phosphate.

Uses.—In the form of burnt hartshorn, calcium phosphate formerly enjoyed a brief popularity in the treatment of *rickets* and *mollities ossium*, in which its use seemed to be indicated upon obvious chemical grounds. In 1851, Benecke suggested that, as it is essential in animals as well as plants to the formation of cells, it might be found useful in certain pathological states of the system characterized by defective nutrition, such as the *scrofulous affections*, and from that time its use has gradually become more frequent, and, in connection with other phosphates, as those of iron, sodium, and potassium, it has acquired no little reputation in different forms of *scrofula*, *mollities ossium*, *rickets*, and even *chronic phthisis*. It is also thought to have proved useful in hastening the union of fractured bones; and Alphonse Milne-Edwards is said to have shown, by experiments upon dogs and rabbits, that in these animals the callus in fractured bones forms more quickly under its use than without it. (*M. T. G.*, May, 1856, p. 489.) Though insoluble in water, it is probably in general dissolved by the gastric liquids, in consequence of the acid present in them; but it is best administered in acid solution, and is at present very extensively used dissolved in lactic acid and emulsified with cod liver oil.

Dose, ten to thirty grains (0.65 to 2.0 Gm.). (See *Syrupus Calcii Lactophosphatis*; also *Pulvis Antimonialis*.)

CALCIU SULPHAS EXSICCATUS. U. S.

EXSICCATED CALCIUM SULPHATE
[Dried Calcium Sulphate]

(cāl'ci-i sŭl'phās ɛx-sic-cā'tŭs)

"A powder containing about 95 percent., by weight, of Calcium Sulphate [$\text{CaSO}_4 = 135.15$], and about 5 percent. of water; prepared from the purer varieties of native gypsum [$\text{CaSO}_4 + 2\text{H}_2\text{O} = 170.91$], by carefully heating until about three-fourths of the water has been expelled. Exsiccated Calcium Sulphate should be kept in well-closed vessels, carefully protected from moisture." *U. S.*

Calcii Sulphas, *Br.* 1885; Dried Gypsum; Plaster of Paris; Exsiccated Sulphate of Calcium; Calcis Sulphas; Sulphate of Lime; Gypsum; Calcium sulfuricum ustum, *P. G.*; Gebrannter Gyps, *G.*

The British Pharmacopœia (1898) dismissed calcium sulphate (dried), but inserted calcium sulphate in the articles employed in chemical testing in the Appendix. The native sulphate is best known as *gypsum*, and in its massive variety as *alabaster*. Gypsum is an abundant natural product, and the quantity mined in the United States has enormously increased in recent years. In 1903 it amounted to 1,041,704 tons, valued at \$3,792,943; in 1904, 940,917 tons, valued at \$2,784,325; and in 1905, 924,107 tons, valued at \$3,105,000. It is officially described as "a fine, white powder, without odor or taste. From moist air it attracts water, becomes granular, and then loses the property of hardening with water. When mixed with half its weight of water, Exsiccated Calcium Sulphate forms a smooth, cohesive paste, which rapidly hardens. It is soluble in about 378 parts of water at 25° C. (77° F.), and in 451 parts at 100° C. (212° F.). In alcohol it is insoluble. It readily dissolves in diluted nitric or hydrochloric acid; also in saturated solutions of potassium nitrate, sodium thiosulphate, and of various ammonium salts. When heated above 204° C. (399.2° F.), Exsiccated Calcium Sulphate becomes anhydrous and loses the property of forming with water a paste which hardens rapidly. Its saturated solution in water is neutral to litmus paper, and forms white precipitates with barium chloride T.S., with ammonium oxalate T.S., and with alcohol. No effervescence should occur on the addition of diluted acids to Exsiccated Calcium Sulphate (absence of carbonate)." *U. S.*

Uses.—Gypsum is used by surgeons for mechanical purposes, but not at all in internal medicine. It is so slightly soluble in water that it may be considered for ordinary purposes insoluble. The solubility of the crystallized sulphate with 2 molecules of water (native gypsum) is, according to Curtman, at 15° C., 1 to 390; at 38° C., 1 to 368; and at 100° C., 1 to 451. The fact has been well established that its solubility varies with the temperature, but, like that of sodium sulphate, very unequally. Thus, according to Poggiale, it is greatest at 35° C. (95° F.), and above or below that temperature gradually diminishes, so that at 100° C. (212° F.), or the boiling point of water, it is very nearly the same as at 5° C. (41° F.), not far from the freezing point. (*J. P. C.*, 4e sér., v. 86.) The other point is that, when deprived of its water by heat, and reduced to the state of a white powder, it rapidly absorbs water added to it, and, from the state of semi-liquid paste into which it is brought with that fluid, hardens without great change of bulk. It is this property which fits plaster of Paris so well for all kinds of moulding; and to this also it owes its peculiar adaptability to the purpose of a splint. To prepare it for use, the gypsum must first be deprived of the greater part of its water by exposure to a heat of 100° C. (212° F.), or from that to 121.1° C. (250° F.). It loses both its molecules of

water of crystallization at a temperature of about 170° C. (338° F.), and is then known as *burnt gypsum*. If heated above 204° C. (399.2° F.) it becomes *dead-burnt*, and does not take up water readily and does not harden. When dehydrated, it is reduced to fine powder, and kept in air tight vessels for use. As thus prepared, if mixed with two parts of water, it forms a semi-liquid cream-like mass, which becomes solid and hard in fifteen or twenty minutes, the temperature rising during the process, as in the slaking of lime. The hydrated gypsum expands in solidifying, hence its advantages in preparing casts,—the expansion causes it to fill accurately all interstices. Cloëz (*Chem. News*, 1903, 58) states that the “setting” of plaster of Paris is due to the succession of three phenomena: 1. Hydration. 2. Partial solution. 3. Solidification of a super-saturated solution. According to T. E. Stark, a medical officer in the British army, flannel is the best material for bandages to be used with gypsum. It should be cut into strips an inch and a half broad and two or three yards long, which should first be spread on a table and rubbed well with the powdered gypsum on both sides, and always in the direction of the thread. The bandages should then be rolled up loosely, and kept for use in air tight cases. Thus prepared, the bandages, first thoroughly wetted, should be rolled round the limb, overlapping at the edges, so as to make a uniform covering. After application, it should be left to harden, which generally happens in fifteen or twenty minutes. A simpler method of using the gypsum for this purpose is, after the application of the bandages, to paint the whole thoroughly and carefully with the milk of gypsum, which will solidify, and enclose the part in a firm case.

Off. Prep.—Calx Sulphurata, *U. S.*

CALCIUM.

CALCIUM

(cǎl'ej-ūm)

Ca = 39.8

This is the metal characteristic of lime, and, consequently, of all calcareous substances. It was obtained by Matthiessen, in 1855, in masses of the size of a pea, by the electrolysis of calcium chloride with a Bunsen battery. It has been recently made on a much larger scale by electrolysis and has become better known. It is, when pure, a yellowish-white crystalline metal, ductile and malleable, with a specific gravity of 1.58 and melting at 760° C. It oxidizes slowly in dry air, more rapidly in moist air, and it must therefore be kept under petroleum.

Calcium is a very abundant element in nature, existing in the mineral kingdom chiefly as a carbonate, in the form of limestone, marble, chalk, and calcareous spar; and as a phosphate

and carbonate in the bones and shells of animals, and as a sulphate in gypsum and selenite.

CALENDULA. *U. S.*

CALENDULA [Marigold]

(cǎ-lên'dú-lǎ)

“The dried ligulate florets of *Calendula officinalis* Linné (Fam. *Compositæ*).” *U. S.*

Mary-bud, Holigold; Fleurs de Tous les mois, Souci, *Fr.*; Ringelblume, Todtenblume, Warzenkraut, *G.*; *Calendula*, *Sp.*

Calendula officinalis, L.—The common marigold of the gardens is too well known to need description, other than that of the Pharmacopœia. Although the *U. S. P.* recognizes only the marigold florets, the whole plant, freshly gathered, is much used by the so-called eclectics and homœopathic practitioners, and was formerly official in the *U. S. Pharmacopœia*.

Properties.—“Florets, 15 to 25 Mm. long, yellow or orange-colored, one- to three-toothed, the short hairy tube occasionally enclosing the remnants of a filiform style and bifid stigma; odor slight and somewhat heavy; taste slightly bitter and faintly saline.” *U. S.* The odor is much stronger in the fresh than in the dry herb, and on exposure to the sun the yellow color fades into whitish. Among its constituents are a bitter principle, and an amorphous substance called *calendulin* (discovered by Geiger most abundantly in the flowers), considered by Berzelius as analogous to bassorin, though soluble in alcohol. *French* or *African Marigold*, so called, is very frequently substituted for the official drug. It is the *Tagetes patula*, L., and *T. erecta*, Linn., both of Mexico. The flowers are readily distinguished by the scales of the involucre being united to form a tube, and by the slender, flattish achenes being crowned with a few chaffy or awned scales. The broadly strap-shaped ray-florets are toothed, and of a light or deep orange color sometimes striped with red. Latour and Magnier de la Source isolated from African marigold a yellow crystalline substance, *quercetagetin*, which Perkin examined and gave the composition $C_{18}H_{10}O_8$. (*P. J.*, 1902, 294.)

Uses.—In the days of therapeutic darkness calendula was thought to be antispasmodic, sudorific, deobstruent, and emmenagogue, and was given in low forms of fever, *scrofula*, *jaundice*, *amenorrhœa*, etc. Both the leaves and the flowers were used; but the latter were preferred, and were usually administered in the recent state in the form of tea. The tincture has been used to a considerable extent as an embrocation in sprains, bruises, etc., and probably is of as much value as simple alcohol.

Dose, from fifteen to sixty grains (1 to 3.9 Gm.).

Off. Prep.—Tinctura Calendulæ, *U. S.*

CALUMBA. U. S. (Br.)

CALUMBA [Columbo]

(ca-lûm'ba)

"The dried root of *Jateorhiza palmata* (Lamarek) Miers (Fam. *Menispermaceæ*)." U. S.
 "The dried transversely cut slices of the root of *Jateorhiza Columba*, Miers." Br.

Calumbæ Radix, Br.; Calumba Root; Radix Columbo; Colomba, U. S. 1850; Racine de Colombo, Fr. Cod.; Colombo, Fr.; Radix Colombo, P. G.; Kolombowurzel, G.; Colombo, It.; Colombo, Raiz de colombo, Sp.; Kalumbo, Port.; Calumb, Mozambique.

The calumba plant was long but imperfectly known. Flowering specimens of a plant gathered by Commerson, about the year 1770, in the garden of Poivre in the Isle of France, and sent to Europe with that botanist's collection, were examined by Lamarek, and described under the name of *Menispermum palmatum*; but its original locality was unknown, and it was only conjectured to be the source of calumba. In the year 1805, Forten, while engaged in purchasing the drug in Mozambique, obtained possession of a living offset of the root, which, being taken to Madras and planted in the garden of Anderson, produced a male plant, which was figured and described by Berry. From the drawing thus made, the plant was referred to the natural family of the *Menispermaceæ*; but, as the female flowers were wanting, some difficulty was experienced in fixing its precise botanical position. De Candolle, who probably had the opportunity of examining Commerson's specimens, gave its generic and specific character, but confessed that he was not acquainted with the structure of the female flower and fruit. This desideratum, however, was supplied by ample drawings sent to England by Telfair of Mauritius, made from plants which were propagated from roots obtained by Owen in 1825, while prosecuting his survey of the eastern coast of Africa. The plant was first placed in the genus *Cocculus*, which was separated by De Candolle from *Menispermum*. Subsequently, J. Miers established a new genus, which has been received by botanists, giving to it the name of *Jateorhiza*. Miers also separated his plant specifically from *C. palmatus* of De Candolle, describing it under the name of *Jateorhiza Columba*. This species is now recognized by the Br. Pharmacopœia, and was formerly also acknowledged by the U. S. Pharmacopœia, but the very careful researches of Hanbury (*Pharmacographia*, 2d ed., p. 23) led him to consider the specific differences as unimportant and inconstant, with which view the botanists of the U. S. 1890 revision coincided. The differences are that in *J. palmata* the lobes at the base of the leaf overlap, and the male inflorescence is nearly glabrous; while in *J. Columba* the basal lobes are rounded, but do not overlap, and the male inflorescence is setose-hispid. The plants are probably only varieties of one species, and it is almost certain that calumba is derived from each of them.

"The plants of the genus, natives of inter-tropical Africa, are all climbers, distinguished by a very peculiar habit, having very large deeply-lobed leaves, upon very long petioles, and clothed with long strigose hairs; their inflorescence is in long slender racemes; the fruit is a drupe containing a putamen covered with a dense hairy coating embedded in the fleshy mesoderm."

Jateorhiza palmata, Miers, *Annals and Mag. of Nat. Hist.*, Feb. 1864, p. 183. B. & T. 13. *Cocculus palmatus*, De Cand., *Syst. Veg.*, i. 523; Woodv., *Med. Bot.*, 3d ed., v. 21; Hooker, *Curtis's Bot. Mag.*, Nos. 2970, 2971.—This is a climbing plant, with a perennial root consisting of several fasciculated, fusiform, somewhat curved, and descending tubers, as thick as an infant's arm. The stems, of which one or two proceed from the same root, are twining, simple in the male plant, branched in the female, round, hairy, and about as thick as the little finger. The leaves, which stand on rounded, glandular, hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each running into one of the lobes. The flowers are small and inconspicuous, and arranged in solitary axillary racemes, which in the male plant are compound, in the female simple, and in both plants are shorter than the leaves.

Jateorhiza Columba, Miers, Br. Pharm.—*Cocculus palmatus*, Wallich, not De Cand.—*Menispermum Columba*, Roxb., *Flor. Ind.*—This species is characterized by "rounded, angularly striate, roughly pilose branches; broadly orbicular, sinuously lobed leaves, with rounded sinuses; the lobes being 5 in number, broadly ovate, acute, mucronately acuminate; the basal deeply divaricate and hence broadly cordate; 7 to 9 nerved, opaque above, on both sides furnished with short, adpressed, somewhat curved, reddish hairs, beneath pale, strongly reticulate with prominent nerves and veins; the petiole somewhat slender, striate, tortuous, and roughly glandular; the racemes axillary, solitary or many; the rachis greatly elongated, striate, bristly, with elongated, smooth, divaricate, almost capillary, subflexuous, few-flowered branches; the flowers sessile, and almost without bracts." (Miers.)

Both of these so-called species are natives of Mozambique, on the southeastern coast of Africa, where they grow wild in great abundance in the thick forests extending from the sea many miles into the interior. The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old root is rejected.

The plant is said to be cultivated both in Africa and the East Indies for the sake of its root, which under the name of *Calumb* is used in dyeing.

Calumba is sent from the Portuguese dominions in Southeastern Africa into India, from whence it goes into general commerce. At one time, when thought to be a product of Ceylon, it was supposed to have derived its name from Columbo, a city of that island, but a much more probable derivation is from the African name of the root above given. (See Lloyd's history of columbo root, *West. Drug.*, 1898, 8.)

Adulterations.—Formerly the high price of calumba led to its frequent adulteration, especially, it is said, with the roots of the *white bryony*, and of *Frasera carolinensis* or *American calumba*, and with the stem of *Coscinium fenestratum*, the *columbo wood* or *false columbo* of Ceylon. According to Stolze of Halle, the American calumba can be readily detected by the fact that while the tincture of true calumba is not affected by ferric sulphate or sesquichloride, and yields with tincture of galls a dirty precipitate, the tincture of *Frasera* becomes dark green with the former and is not affected by the latter reagent. *Coscinium fenestratum*, a bitter tonic used in Ceylon, is at once to be distinguished by its being a stem, not a root, and is said not to have appeared upon the market for many years. At present, owing to its great cheapness, calumba root seems to be very rarely adulterated. (See *P. J.*, 1901, 502, and Dec. 1904.)

Properties.—It is officially described in the U. S. Pharm. as "in transverse, circular or oval, biconcave sections, 2.5 to 5 Cm. in diameter and 2 to 12 Mm. thick; externally greenish-brown and roughly wrinkled; internally yellowish or grayish-yellow, with a few interrupted circles of fibrovascular bundles, distinctly radiate in the outer portion, with a dark cambium; fracture short, mealy; odor slight; taste slightly aromatic, very bitter." *U. S.* Along with the disks are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow, slightly greenish color internally, but covered with a brownish, wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is often marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest color, are most compact and uniform, and least worm eaten. According to the British Pharmacopeia "the cork is brownish and wrinkled, the cortex thick, marked with radiating lines, and separated by a dark line from the wood, in which the vessels are arranged in narrow radially elongated groups. The parenchymatous tissue is largely developed, and contains numerous starch grains, mostly simple with eccentric hilum." *Br.* The odor of calumba is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is easily pulverized. The powder is greenish, becoming browner with age,

and deepening when moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities.

Planche analyzed calumba in 1811, and found it to contain a nitrogenous substance, probably albumen, in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of volatile oil, salts of calcium and potassium, ferric oxide, and silica. Wittstock of Berlin, afterwards isolated a principle, which he called *columbin*. This crystallizes in beautiful transparent quadrilateral prisms of the formula $C_{21}H_{32}O_7$, is without odor, and is extremely bitter. It is but very slightly soluble in water, more soluble in alcohol, ether, or chloroform, and imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It is obtained by exhausting calumba by means of alcohol of the sp. gr. 0.835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days until crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother waters still contain a considerable quantity of columbin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution to crystallization.

From the researches of Bödecker it appears that another bitter principle exists in calumba, which corresponds in composition and chemical relations with *berberine*, the active principle of *Berberis vulgaris*, and is assumed to be identical with that substance. It was obtained by exhausting calumba with alcohol (sp. gr. 0.889), distilling off the alcohol, allowing the residual liquor to stand for three days so as to deposit the columbin, evaporating the supernatant liquid together with the aqueous washings of the columbin to dryness, exhausting the residue with boiling alcohol (sp. gr. 0.863), treating the solution thus obtained as the former one, submitting the residue to the action of the boiling water, filtering, and adding hydrochloric acid, collecting the precipitate thus formed on a filter, drying it with bibulous paper, and finally, in order to separate adhering acid, dissolving it in alcohol, and precipitating with ether. The result was an imperfectly crystalline, bright yellow powder, of a disagreeable, bitter taste, supposed to be *berberine hydrochloride*. It is stated that berberine is present in calumba in much larger proportion than columbin, and, being freely soluble in hot water and alcohol, while columbin is but slightly so, is probably more largely extracted in the ordinary liquid preparations of the root. (*A. J. P.*, xx. 322.) A third constituent, *columbic acid*, was also discovered by Bödecker. It is yellow, amorphous,

nearly insoluble in cold water, but dissolving in alcohol and in alkaline solutions. It tastes somewhat less bitter than *columbin*.

P. E. Alessandri isolated *calumbine* (which he considers an alkaloid) by the following process. An infusion of calumba is made with a 3 per cent. solution of oxalic acid; the yellow bitter liquid is neutralized with ammonia and evaporated to one-third its bulk; it is, when cooled, treated with ether, separated, and the ethereal solution on evaporation yields pure white calumbine. (*L'Orosi*, v. 1; *P. J.*, 1882, p. 995.) Alessandri obtains *berberine* from calumba by neutralizing a cold infusion, made with diluted oxalic acid (3 per cent.), with baryta; the precipitate which is produced is separated. The liquid is heated, allowed to stand for twenty-four hours to allow the barium oxalate to deposit, filtered, and then a current of carbonic acid is passed through to remove baryta. It is then treated by shaking the ammoniacal liquid with ether as in Alessandri's process for calumbine (see above), and, after the ethereal layer is separated, the aqueous liquid is evaporated to dryness. Berberine is obtained from the extract by treating the latter with alcohol, the berberine being purified by washing with ether. *Columbic acid* may be obtained from the precipitate produced by the addition of barium oxide to the oxalic acid infusion. (*L'Orosi*, v. 1; *P. J.*, 1882, p. 995.) Bocchiola (*Y. B. P.*, 1891, p. 162) states that the older roots contain more of the active principles than the younger ones. He found that the inner and the outer portions of calumba also vary in their constituents; thus in the woody or inner part he found the following percentages: calumbine 1.90, berberine 0.72, ether extract 0.80, alcoholic extract 3.86, diluted alcoholic extract 17.80, ash 6. In the cortical or outer part he found calumbine 1.42, berberine 1.43, ether extract 0.70, alcoholic extract 3.89, diluted alcoholic extract 17.96, ash 5. Hilger obtained from calumba: columbin, columbic acid, and berberine in a pure condition. He assigns to columbin the formula $C_{21}H_{24}O_7$, and to columbic acid $C_{21}H_{22}O_8$. (*Zeit. Oest. Apoth. Ver.*, 1896, No. 1, 8-14.) Haensel (*P. J.*, 1904, 216) obtained from calumba a volatile oil which exists in very small quantities (0.00568 per cent.). It has a peculiar odor and bitter taste.

There can be little doubt that both columbin and berberine contribute to the remedial effects of calumba. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by infusion of galls, and by solutions of lead acetate and subacetate, but the bitterness is not affected.

Uses.—Calumba is a mild bitter tonic, free from astringency. It is very useful in functional atonic conditions of the digestive organs. It is frequently administered in combination with other tonics, aromatics, mild cathartics, and antacids. A favorite remedy of Geo. B. Wood for the permanent cure of a disposition

to the accumulation of *flatus* in the bowels was an infusion made with half an ounce of calumba, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in the dose of a wineglassful three times a day. Calumba is much used by the natives of Mozambique in *dysentery* and other diseases. (Berry.) It was first introduced to the notice of the profession in Europe by François Redi, in the year 1685. (See *Infusum Calumbæ*; also *Fluidextractum Calumbæ*, and *Tinctura Calumbæ*.)

Dose, of the powder, from ten to thirty grains (0.65 to 2.0 Gm.), which may be repeated three or four times a day.

Cod.*; *Chaux*, *Chaux vive*, *Fr.*; *Calcaria Usta*, *P. G.*; *Aetzkalk*, *Kalk*, *Gebrannter Kalk*, *G.*; *Ossido di calcio*, *Calce*, *It.*; *Cal viva*, *Sp.*

Lime, which is ranked among the alkaline earths, is a very important pharmaceutical agent, and forms the principal ingredient in several standard preparations. It is a very abundant natural production. It is never found free, but mostly combined with acids, as with carbonic acid in chalk, marble, calcareous spar, limestone, and shells; with sulphuric acid in the different kinds of gypsum; with phosphoric acid in the bones of animals; and with silica in a great variety of minerals.

Preparation.—Lime is prepared by calcining, by a strong heat, some form of the native carbonate. The carbon dioxide is thus expelled, and the lime remains. When the lime is intended for delicate chemical operations, it may be obtained from pure white marble or oyster-shells. For the purpose of the arts it is procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way it is generally impure, being of a grayish color, and containing alumina, silica, ferric oxide, and occasionally a little magnesia and manganese oxide.

The official lime of the United States and British Pharmacopœias is the lime of com-

merce, and not quite pure. It may be obtained purer by exposing pure white marble, broken into small fragments, in a covered crucible, to a full red heat for three hours, or until the residue, when slaked and suspended in water, no longer effervesces on the addition of hydrochloric acid.

Properties.—Lime is in "hard, white, or grayish-white masses, which, in contact with the air, gradually attract moisture and carbon dioxide, and fall to a white powder; odorless, and having a caustic taste. Soluble in about 760 parts of water at 25° C. (77° F.), and in about 1600 parts of boiling water; insoluble in alcohol. It forms readily soluble salts with diluted acetic, hydrochloric, or nitric acids. When sprinkled with about half its weight of water, Calcium Oxide becomes heated, and is gradually converted into a white powder (calcium hydroxide or slaked lime). When this is mixed with about 3 or 4 parts of water, it forms a smooth magma (milk of lime). Its aqueous solution has an alkaline reaction upon red litmus paper. If 1 Gm. of Calcium Oxide be slaked and then thoroughly mixed with 50 Cc. of water, and the greater portion of the milky liquid decanted, the addition of hydrochloric acid to this residue should not cause more than a slight effervescence (limit of carbonate). For applying tests of identity and of purity, 5 Gm. of Calcium Oxide, after slaking, are mixed with 100 Cc. of distilled water, followed by hydrochloric acid, added drop by drop, with agitation until solution takes place. The resulting solution should, after boiling and cooling, be of acid reaction and not deposit more than 0.025 Gm. of insoluble matter. With a portion of this solution, after neutralizing with ammonia water, ammonium oxalate T.S. produces a white precipitate of calcium oxalate, insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

Lime is calcium oxide, and consists of one atom of calcium 39.80, and one of oxygen 15.88. Its sp. gr. is 3.08, while the hydroxide has the sp. gr. 2.078. (Filhol.) Its solubility in water is greatly increased by the addition of sugar or glycerin. (See *Syrupus Calcis*.) It is distinguished from the other alkaline earths by forming a very deliquescent salt (calcium chloride) by reaction with hydrochloric acid, and a sparingly soluble one with sulphuric acid. All acids, acidulous, ammoniacal, and metallic salts, borates, alkaline carbonates, and astringent vegetable infusions are incompatible with it.

Uses.—Lime acts externally as an escharotic, and was formerly applied to ill-conditioned ulcers. The lime ointment of Spender is made by incorporating four parts of washed slaked lime with one part of fresh lard and three parts of olive oil, previously warmed together. Mixed with potassium hydroxide, lime forms *Potassa cum Calce*, official in the U. S. P. 1890. As an internal remedy, it is converted into hydroxide and this is administered in solution. (See *Liquor Calcis*; also *Syrupus Calcis*.)

CALX CHLORINATA. U. S., Br.

CHLORINATED LIME CHLORINATED CALCIUM
OXIDE [*Calx Chlorata*, *Pharm.* 1890,
Chloride of Lime]

(cālġ ħhlŏ-rġ-nā'ta)

"A compound resulting from the action of chlorine upon calcium hydroxide, and containing not less than 30 percent. of available chlorine. It is often improperly called 'Chloride of Lime.' It should be kept in well-closed vessels, in a cool and dry place." *U. S.* "A product obtained by exposing slaked lime to the action of chlorine gas until absorption ceases." *Br.*

Hypochlorite of Lime or Calcium, Oxymuriate of Lime or Calcium, Chloris Calcicus, Chloruretum Calcis, Calcis Chloridum, Calcii Hypochloris, Calcium hypochlorite, Bleaching Powder; Chlorure de Chaux sec, *Fr. Cod.*; Poudre de Tennant ou de Knox, *Fr.*; Calcaria Chlorata, *P. G.*; Chlorkalk, Bleichkalk, *G.*; Cloruro di calcio, *It.*; Hipoclorito calcico clorurado, *Sp.*

This compound, originally prepared as a bleaching agent in 1798 by Tennant of Glasgow, is now enormously used both in the arts and in medicine.

The following is an outline of the process for making chlorinated lime on the large scale. A rectangular chamber is constructed, generally of silicious sandstone, the joints being secured by a cement of pitch, rosin, and dry gypsum. At one end it is furnished with an air tight door, and on each side with a glass window, to enable the operator to inspect the process during its progress. The slaked or hydrated lime is sifted, and placed on wooden trays eight or ten feet long, two feet broad, and one inch deep. These are piled within the chamber to a height of five or six feet on cross-bars, by which they are kept about an inch asunder in order to favor the circulation of the gas over the lime. The chlorine is generated in a leaden vessel nearly spherical, the lower portion of which is surrounded with an iron case, leaving an interstice two inches wide, intended to receive the steam for the purpose of producing the requisite heat. In the leaden vessel are five apertures. The first is in the centre of the top, and receives a tube which descends nearly to the bottom, and through which a vertical stirrer passes, intended to mix the materials, and furnished at the lower end with horizontal cross-bars of iron, or of wood sheathed with lead. The second is for the introduction of the sodium chloride and manganese. The third admits a siphon-shaped funnel, through which the sulphuric acid is introduced. The fourth is connected with a pipe to lead off the chlorine. The fifth, which is near the bottom, receives a discharge pipe passing through the iron case and

intended for drawing off the residue of the operation. The pipe which conducts the chlorine, terminates, under water, in a leaden chest or cylinder, where the gas is washed from hydrochloric acid. From this intermediate vessel the chlorine finally passes, by means of a rather large leaden pipe, through the ceiling to the chamber containing the lime. The process of impregnation generally lasts four days, this time being necessary to form a good bleaching powder. If it be hastened, heat will be generated, which will favor the production of calcium chloride, with a proportional diminution of chlorinated lime.

A more expeditious method of manufacture is now used, both in Germany (where it originated) and in this country, where bleaching powder is made from electrolytic chlorine. A series of horizontally placed drums or cylinders provided with revolving endless screws receive the dry calcium hydroxide, which, from its entering the top cylinder until discharged from the bottom one, meets a continuous stream of chlorine gas going in the opposite direction.

Several electrolytic processes for the decomposition of sodium and potassium chlorides have been introduced in recent years, whereby caustic alkali on the one hand and chlorine on the other hand are produced. The chlorine liberated is almost entirely utilized in the manufacture of bleaching powder. Large quantities are thus produced at present (1905) at Niagara Falls.

The importation of bleaching powder in 1900 amounted to 136,879,429 lbs., but in 1904 had diminished to 98,742,938 lbs. The domestic production has grown greatly in recent years (69,400,000 lbs. in 1902) and now exceeds the amount imported.

Properties.—Chlorinated lime is "a white, or grayish-white, granular powder, exhaling the odor of hypochlorous acid, having a repulsive, saline taste, and becoming moist and gradually decomposing on exposure to air. In water or in alcohol it is only partially soluble. An aqueous solution first colors red litmus paper blue, and then bleaches it. If Chlorinated Lime be dissolved in diluted acetic acid, an abundance of chlorine gas will be evolved, and only a trifling residue remain undissolved. From this solution ammonium oxalate T.S. throws down a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid." *U. S.* When perfectly saturated with chlorine it dissolves almost entirely in water. When exposed to heat, it gives off oxygen and some chlorine, and is converted into calcium chloride. It is incompatible with the mineral acids, carbon dioxide, and the alkaline carbonates. The acids evolve chlorine copiously, and the alkaline carbonates cause a precipitate of calcium carbonate. (*See Liquor Sodæ Chlorinatae.*)¹

Chlorinated lime is an oxidizing agent, the oxygen being derived from water, the hydrogen of which unites with the chlorine to form hydrochloric acid. It has a powerful action on organic matter, converting sugar, starch, cotton, linen, and similar substances into formic acid, which unites with the lime. (W. Bastick.) It also acts energetically on the volatile oils, including oil of turpentine, producing chloroform. (*J. P. C.*, Mars, 1855.)

Composition.—The composition of chlorinated lime is represented by the formula CaOCl_2 , and it was formerly supposed to be a direct compound of lime with chlorine. This view, however, is not consistent with its reactions, for when distilled with diluted nitric acid it readily yields a distillate of aqueous hypochlorous acid, and when treated with water it is resolved into calcium chloride and hypochlorite, the latter of which may be separated in crystals by exposing the filtered solution to a freezing mixture, or by evaporating it in a vacuum over oil of vitriol and leaving the dense frozen mass to thaw upon a filter. A solution of calcium chloride mixed with hypochlorite then passes through, and feathery crystals remain on the filter, very unstable, but consisting, when recently prepared, of hydrated calcium hypochlorite, $\text{Ca}(\text{OCl})_2 \cdot 4\text{H}_2\text{O}$. This seems, at first sight, to show that the bleaching powder is a mixture of calcium chloride and hypochlorite, formed according to the equation

but if this were its true constitution, the powder when digested with alcohol ought to yield a solution of calcium chloride containing half the chlorine of the original compound, which is not the case. Its constitution is, therefore, better represented by the formula $\text{Ca} \begin{Bmatrix} \text{Cl} \\ \text{OCl} \end{Bmatrix}$ suggested by

Odling, this molecule being decomposed by water into chloride and hypochlorite in the manner just explained, and yielding with diluted nitric acid or sulphuric acid a distillate containing hydrochloric and hypochlorous acids,

(Lunge² and Schaeppi, *A. J. P.*, 1881; Lunge and Naef, *Ber. d. Chem. Ges.*, 1883.) Lunge

carbon dioxide, which sets them free by combining with the lime. But it would seem that, even when closely confined, it sometimes at least gives off gaseous matter, as we have an account of a well-stoppered bottle containing it having been broken by a violent explosion, without any peculiar exposure to heat. (*See A. J. P.*, 1861, p. 72.) Barreswill has found that the subjection of chlorinated lime to strong pressure greatly diminishes the tendency to decomposition. It is rendered in this way as hard as a stone, and may be kept long without undergoing change. (*Chem. News*, No. 58, p. 33.)

²According to Lunge's investigations, the best temperature for the absorption of chlorine by calcium hydroxide is 40° to 45° C.; from pure calcium hydroxide a bleaching powder of 43 per cent. active chlorine can be produced, in which case allowance for 4 per cent. of moisture in the hydroxide is made; strong mineral acids, when not used in excess, liberate only hypochlorous acid; dry carbon dioxide at normal temperature does not set free any chlorine, but at moderately elevated temperature drives off almost all the chlorine.

¹ Chlorinated lime constantly becomes weaker on exposure to air, giving off chlorine or hypochlorous acid, probably through the influence of the atmospheric

and Bachofen (*Zeit. angew. Chem.*, 1893, 326) have determined the specific gravities of chlorinated lime solutions at 15° C. (See *Proc. A. Ph. A.*, 1894, 579.)

Impurities and Tests.—Chlorinated lime may contain a great excess of lime, from imperfect impregnation with the gas. This defect will be shown by the large proportion insoluble in water. If it contain much calcium chloride, it will be quite moist, which is always a sign of inferior quality. When long and insecurely kept, it deteriorates from the gradual formation of calcium chloride and calcium carbonate. Several methods have been proposed for determining its bleaching power, which depends solely on the proportion of loosely combined chlorine. Walter proposed to add a solution of the bleaching powder to a standard solution of indigo sulphate, in order to ascertain its decolorizing power; but the objection to this test is that the indigo of commerce is very variable in its amount of coloring matter. The oxidation of an arsenous acid solution is largely used in practice. Lunge (*Ber. d. Chem. Ges.*, 1886, p. 869) has also proposed to use hydrogen dioxide (H_2O_2) solution for the valuation of bleaching powder. The two solutions liberate oxygen in exactly equal amount. This is measured in a nitrometer. According to Wittstein and Claude, the test of ferrous sulphate which was formerly official is not reliable. The U. S. P. volumetric method, which is based upon that of the British Pharmacopœia, is preferred. "Introduce into a stoppered weighing-bottle between 3 and 4 Gm. of Chlorinated Lime and weigh accurately; triturate this thoroughly with 50 Cc. of water, transfer the mixture to a graduated vessel, together with the rinsings, and add sufficient water to make 1000 Cc. After thoroughly shaking, add to 100 Cc. of the mixture 1 Gm. of potassium iodide, 5 Cc. of diluted hydrochloric acid, and sufficient tenth-normal sodium thiosulphate V.S. for complete decolorization. Multiply the number of Cc. of tenth-normal sodium thiosulphate V.S. consumed, by 0.3518, and divide this product by one-tenth of the weight of the Chlorinated Lime taken; the quotient represents the percentage of available chlorine present." U. S.

The following is the test given in the British Pharmacopœia: "0.5 gramme of Chlorinated Lime, mixed with 1.5 grammes of *potassium iodide* dissolved in 200 cubic centimetres of *water*, produces, when acidulated with 6 cubic centimetres of *hydrochloric acid*, a reddish solution, which requires for the discharge of its color at least 46.8 cubic centimetres of the *volumetric solution of sodium thiosulphate*, corresponding to 33 per cent. of available chlorine." Br. In this process iodine is separated by the chlorine in equivalent quantity, and imparts color to the liquid, which is removed by the sodium thiosulphate, by forming colorless compounds with the iodine, and the quantity required for this purpose measures the quantity

of iodine, and consequently that of the chlorine, present in the chlorinated solution. (See *Sodii Thiosulphas*.)

Uses.—Chlorinated lime, externally applied, is a desiccant and disinfectant, and has been used with advantage in solution, as an application to ill-conditioned *ulcers*, *burns*, *chilblains*, and *cutaneous eruptions*, especially *itch*; as a gargle in *putrid sore throat*; and as a wash for the mouth to disinfect the breath, and for *ulcerated gums*. Internally, it is stimulant and alterative. It has been used occasionally internally, in *adynamic dysentery*, *typhus fever*, and various other *low diseases*; it may be considered as therapeutically equivalent to chlorine. The dose internally is from three to six grains (0.2 to 0.4 Gm.), dissolved in one or two fluidounces (30 to 60 Cc.) of water, filtered and sweetened with syrup. It should never be given in pills. As it occurs of variable quality, and must be used in solution more or less dilute, according to the particular purpose to which it is to be applied, it is impossible to give any very precise directions for its strength as an external remedy. From one to four drachms of the powder added to a pint of water, and the solution filtered, will form a liquid within the limits of strength ordinarily required. For the cure of *itch*, Derheims has recommended a much stronger solution—three ounces of the chloride to a pint of water, the solution being filtered, and applied several times a day as a lotion, or constantly by wet cloths. When applied to *ulcers*, their surface may be covered with lint dipped in the solution. When used as an ointment to be rubbed upon *scrofulous enlargements* of the lymphatic glands, this may be made of a drachm of the chloride to an ounce of lard. Chlorinated lime is less eligible for some purposes than the solution of chlorinated soda. (See *Liquor Sodæ Chlorinatæ*.)

Chlorine gas is a very active germicide, and, as chlorinated lime affords the best practical method of using it for ordinary disinfecting purposes, it seems proper to discuss the subject at this place. It has been proved by the concurrent results of numerous experimenters that chlorine, if present in the proportion of one part in one hundred in the atmosphere of a room, is able to destroy *disease germs*, provided that the air and the objects are moist, and that the exposure continues for upwards of one hour. In the case of any infected room or confined space, as the hold of a ship, it seems to us, however, that the endeavor should be to have a larger proportion of the chlorine gas present for several hours, and, if it can be readily accomplished, steam should also be allowed to enter with the gas, so as to make sure that all parts shall be thoroughly moistened. The importance of this is shown by the experiments of Fiseher and Proskauer, who found that dry anthrax spores maintained their integrity for one hour when exposed to the action of a dry chlorine atmosphere containing about forty-five per cent. of chlorine, whereas

moistened spores were killed by an hour's exposure to a moist atmosphere containing four per cent. of chlorine. Sternberg found that six hours' exposure of vaccine lymph upon ivory points to a moist atmosphere containing one part of chlorine in one hundred was sufficient to destroy the infective power of the lymph. Chlorine is not only germicidal, but it also has the power of decomposing hydrogen sulphide compounds, and is thereby a deodorant. In all these employments of chlorine it must be remembered that it is not possible for human beings to breathe a chlorinated air, and that the apartment must be, therefore, empty, and also as hermetically sealed as possible to prevent the escape of gas. The experiments of Duggan show that the hypochlorites as derived from chlorinated lime are very active germicides, one part to four hundred being capable of destroying moist germs in two minutes, and six parts to ten thousand killing the spores of the anthrax-bacillus in six hours. A half of one per cent. of the hypochlorites in solution is said to be sufficient to destroy spores almost instantly.

Ordinary bleaching powder contains from twenty-five to forty per cent. of available chlorine; one part of the powder to one hundred of water is strong enough for ordinary purposes. The odor and taste of this solution are such that it can scarcely be considered a dangerous poison, and it has been affirmed, although with doubtful correctness, that such solution will not injure clothing, bedding, etc. The cost of bleaching powder for use in small quantities is so slight that even a saturated solution may be prepared for use in the sickroom at a nominal cost. *For the destruction of disease germs in urine, fecal discharges, sputa, etc., a saturated solution of bleaching powder appears to be in all respects the best disinfectant known.* As it is important to destroy the germs as soon as possible, this solution should be put into the receptacle to be used by the patient *before* the discharges are ejected into them. As the chlorinated solution attacks metals, the spit cups, etc., should be of china or glass.

In consequence of its powers as a disinfectant, chlorinated lime is a very important compound in its application to medical police. It may be used with advantage for preserving bodies from exhaling an unpleasant odor, before interment, in the summer season. In juridical exhumations its use is indispensable, as it effectually removes the disgusting and insupportable fetor of the corpse. The mode in which it is applied, in these cases, is to envelop the body with a sheet completely wet with a solution made by adding about a pound of the powder to a bucketful of water. This solution may also be employed for disinfecting dissecting rooms, privies, common sewers, docks, and other places with offensive effluvia.

Chlorinated lime acts exclusively by its chlorine, which, being loosely combined, is disen-

gaged by the slightest affinities. It should, therefore, be carefully kept from contact with the air and organic substances, which cause rapid loss of chlorine, and the modern method of putting it up for ordinary use in hermetically sealed pasteboard or zinc boxes is a great convenience. R. C. Bicknell examined commercial chlorinated lime put up in boxes for available chlorine; he found the top layers usually deficient in strength, but in the interior from 30 to 35 per cent. of chlorine. Some of the packages assaying 30 per cent. of chlorine were more than a year old. (*A. J. P.*, 1886, p. 593.) Investigations made more recently show that variations in the percentage of chlorine are found in the chlorinated lime put up in packages. See Puckner, Stephens, Harding (*Proc. A. Ph. A.*, 1898, 905). All acids, even carbonic, disengage it, and, as this acid is a product of animal and vegetable decomposition, noxious effluvia furnish the means, to a certain extent, of their own disinfection; but the stronger acids disengage the chlorine far more readily, and among these sulphuric acid is the most convenient. Accordingly, the powder may be dissolved in a very dilute solution of this acid; or a small quantity of the acid may be added to an aqueous solution ready formed, if a more copious evolution of chlorine be desired than that which takes place from the mere action of the carbon dioxide of the atmosphere.

Chlorinated lime may be advantageously applied to the purpose of purifying offensive water, a property which makes it invaluable on long voyages. When used for this purpose, from one to two ounces of the chloride may be mixed with about sixty-five gallons of the water. The water must afterwards be exposed for some time to the air, and allowed to settle, before it is fit to drink. Chlorinated lime is rarely used internally.

Dose, official, four grains (0.26 Gm.).

CALX SULPHURATA. *U. S.*, *Br.*

SULPHURATED LIME [Crude Calcium Sulphide]

(cāl-x sūl-phū-rā'ta)

"A mixture containing at least 60 percent. of calcium sulphide [$\text{CaS} = 71.63$], together with unchanged calcium sulphate [$\text{CaSO}_4 = 135.15$], and carbon, in varying proportions." *U. S.*

"A mixture containing not much less than 50 per cent. of calcium sulphide, CaS , with calcium sulphate and carbon. It may be prepared by reducing native calcium sulphate by means of carbon." *Br.*

Calcium Sulphuratum, Calcii Sulphidum; Calcaria Sulfurata, Hepar Sulphuris Calcareum, Hepar Calcis; Sulphide of Calcium; Sulfure de Chaux, *Fr.*; Kalkschwefelleber, *G.*

* "Exsiccated Calcium Sulphate, in fine powder, seventy grammes [or 2 oz. av., 205 grains];

Charcoal, in fine powder, *ten grammes* [or 154 grains]; Starch, *two grammes* [or 31 grains]. Mix the powder thoroughly, pack the mixture lightly into a crucible, cover this loosely, and heat it to bright redness, until the contents have lost their black color. Allow the crucible to cool, reduce the product to powder, and at once transfer it to small, glass-stoppered vials." *U. S.*

The U. S. Pharmacopœia of 1890 abandoned the former process of preparing this substance, and adopted the British process (1885) with some modifications; this was retained in the U. S. P. (8th Rev.). The present British Pharm. (1898) does not give a detailed process.

By subjecting a mixture of seven parts of calcium sulphate and one part of charcoal to a red heat, in a covered crucible, carbonic oxide is formed, and calcium sulphide is produced,

A less convenient method is to pass hydrogen sulphide over red-hot lime, but if the lime be pure a better product is insured. This preparation, which was introduced into both Pharmacopœias, is of doubtful utility, particularly in the form in which it is produced. The amount of calcium sulphide present must vary considerably according to circumstances. The medicinal activity is measured alone by the quantity of sulphide in the finished preparation, calcium sulphate, the other constituent, being inert. It is to be regretted that a method of purification was not appended.

Properties.—Sulphurated lime is officially described as "a pale gray powder, exhaling a faint odor of hydrogen sulphide, having a nauseous and alkaline taste; gradually decomposing by exposure to moist air. Very slightly soluble in cold water, more readily in boiling water, which partially decomposes it; insoluble in alcohol. When Sulphurated Lime is decomposed by diluted acetic acid, calcium acetate is formed, hydrogen sulphide gas is evolved, and a residue of calcium sulphate and carbon remains. The filtrate from this yields with ammonium oxalate T.S. a white precipitate, insoluble in acetic acid, but soluble in hydrochloric acid." *U. S.*

Tests.—"If 1 Gm. of Sulphurated Lime be added to a cold solution of 2.08 Gm. of cupric sulphate in 50 Cc. of water, followed by 10 Cc. of diluted hydrochloric acid, added in small portions, with constant stirring, and the mixture digested on a water-bath for 15 minutes and filtered, the addition of an excess of ammonia water should impart no color to the filtrate (presence of at least 60 percent. of pure Calcium Sulphide)." *U. S.* The British Pharmacopœia describes it as "a grayish-white powder with a smell of hydrogen sulphide. If 0.8 gramme be mixed with a cold solution of 1.4 grammes of *copper sulphate* in 50 cubic centimetres of *water*, and, after the addition of a little *hydrochloric acid*, the mixture be well stirred and heated to a temperature approaching that of ebullition until all action

has ceased, and then filtered, the filtrate should give no red color with *solution of potassium ferrocyanide* (presence of a due proportion of sulphide)." *Br.*

Calcium sulphhydrate, or *calcium hydrosulphide*, $\text{Ca}(\text{SH})_2$, is formed when hydrogen sulphide is passed into milk of lime as long as it is absorbed. It is in the form of a paste of a greenish-gray color, and exhales a strong odor of hydrogen sulphide.

Uses.—It is used as a *depilatory*, and is applied in a layer on the part which is to be deprived of hair. At the end of fifteen minutes it is removed with a wet sponge, which at the same time detaches the hairs. On account of this preparation giving out hydrogen sulphide, it should not be applied near the mouth or nose. An impure aqueous solution of calcium sulphide, necessarily containing calcium thiosulphate from the manner of its preparation, is used with great success, in Belgium, in *itch*, the cure of which it effects in a few hours. It is made by boiling together one part of sublimed sulphur, two of lime, and ten of water. The liquid is allowed to cool, and the clear part poured off and kept in well-stoppered bottles. For an explanation of the reaction which takes place, see *Sulphur Præcipitatum*. The patient, after having been well washed with soap and tepid water in a bath, is rubbed over with the liquid, which is allowed to dry on the skin for a quarter of an hour. A second bath is then taken, which completes the cure. The preparation, when it dries, leaves on the skin a thin layer of the sulphur compound, which destroys the itch insect and its eggs.

Sulphurated lime has been strongly recommended by Ringer, Dühring, and other authorities as a remedy for *furuncular eruptions*, and it has also been used successfully in *acne*.

Dose, one-tenth to one-half grain (0.006 to 0.032 Gm.).

CAMBODIA. U. S., Br.

GAMBOGE

(cām-bō'gā)

"A gum-resin obtained from *Garcinia Hanburi* Hooker filius (Fam. *Guttiferæ*)." *U. S.*
 "A gum-resin obtained from *Garcinia Hanburi*, Hook. f." *Br.*

Gambogia. *U. S. Pharm.* 1870: Gummi-resina gutta (s. gutti), Gutta Gamba, Cambodia; Gomme-gutte, *Fr. Cod.*; Gutte, *Fr.*; Guttli, *P. G.*; Gummigutt, *G.*; Gumma gotta, *It.*; Gutagamba, Goma gutta, *Sp.*

Under the name of *Cambogia Indica*, *Indian Gamboge*, the British Addendum recognizes a gum-resin obtained from the *Garcinia Morella*, Desrouss. Several plants belonging to the natural family of *Guttiferæ*, growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure and bears a close resemblance to gamboge; but it is only from a particular tree, growing in Siam, that the official gum-resin is procured. According

to observations of Baildon and Jamie, gamboge is obtained exclusively from the province of Cambodia, the plant not being found in any other part of Siam nor in Cochin-China. (*J. P. C.*, Juillet, 1874.) Formerly the United States and all the British Pharmacopœias ascribed it to *Stalagmitis cambogioides*. Both the genus and the species were established by Murray of Göttingen, in 1788, from dried specimens belonging to König, procured in Ceylon; and, from information derived from the same source, it was conjectured by Murray that the tree yielded not only the gamboge of Ceylon, but also that collected in Siam. On this authority the British Colleges made the references alluded to. But it was ascertained by Graham of Edinburgh, that there is no such plant as *Stalagmitis cambogioides*; the description of Murray having been drawn up from accidentally conjoined specimens of two trees belonging to different genera, one being the *Xanthochymus ovalifolius* of Roxburgh, and the other the *Hebradendron cambogioides* of Graham. By several botanists the gum-resin has been ascribed to *Garcinia Cambogia*, also a tree of Ceylon belonging to the Guttiferæ and yielding a yellowish concrete juice; but a specimen of this juice, sent to Edinburgh, was found by Christison to differ from gamboge both in composition and appearance, being of a pale lemon-yellow color. Thus it appears that neither of these references is correct; and, besides, the fact seems to have been overlooked that commercial gamboge is never obtained from Ceylon, but exclusively from Siam and Cochin-China. A gum-resin from Ceylon having been found similar in composition to the gamboge of commerce, and the tree which produced it having been referred by Graham to a new genus and named by him *Hebradendron cambogioides*, the Edinburgh College, in the last edition of its Pharmacopœia, was induced to adopt this Ceylon gamboge as official, and to recognize the name proposed by Graham for the tree producing it. But, as this variety is never found in Western commerce, and exists only in cabinets, or in the bazaars of India, it scarcely merited a place in an official catalogue; moreover, the genus *Hebradendron* is not acknowledged by botanists. The *H. cambogioides* is the *Garcinia pictoria* of Roxburgh (*Flor. Ind.*, ii. 627), which Sir Joseph Hooker considers to be a variety of the *G. Morella*, Desrouss., though Beddome keeps it distinct on account of its having the fertile flower bearing "the stamens in bundles and the stigma very small and 4-lobed." Several years since, Christison received from Singapore specimens of the gamboge plant cultivated in that island, and derived from Siam, which proved to be a *Garcinia*, differing from the *G. elliptica* of Wallich chiefly in having its male flowers upon pedicels. Subsequently Hanbury obtained from the same source numerous specimens of the same plant, and was enabled to confirm the statement of Christison; but he also found that the plant

approached very near to the *Garcinia Morella* of Desrousseaux, from which it could be distinguished only by its pedicellate flowers. These specimens were afterwards submitted to the inspection of Thwaites in Ceylon, who is perfectly familiar with the *Garcinias* of that island, and were pronounced by him to belong to a variety of *G. Morella*, scarcely differing from the Ceylon plant, except in having pedicelled instead of sessile flowers; for these two varieties the names of *G. Morella*, var. *sessile*, and *G. Morella*, var. *pedicellata*, were proposed. Sir Joseph Hooker, however, determined (*Journ. Linn. Soc.*, xiv. 485) that the var. *pedicellata* is a distinct species, differing from *G. Morella* in having not only its flowers pedicellate, but also its leaves more ovate and much larger, and its fruit larger; he very properly gave it the specific name of *Hanburii* to commemorate the contributions of the late Mr. Hanbury to pharmaceutical science, and his connection with the history of the present plant. According to the researches of Beckett, *G. Hanburii* is confined to the islands and sea coast of the Gulf of Siam, where it is known as "*Ton Rong*," and where it grows to the height of fifty feet, with a diameter of twelve inches. *Ceylon gamboge*, derived from the *Hebradendron cambogioides* of Graham (*Cambogia Gutta*, L., *Garcinia Morella*, De Cand., *G. pictoria*, Roxb.), is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Christison were in flattish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. It resembled coarse gamboge, and was identical in composition. In Ceylon it is used as a pigment and purgative. (Christison.) *New Caledonian Gamboge*, derived from *Garcinia Collina*, Vieil., is described by Heckel and Schlagdenhauffen as very similar in its appearance and reactions to ordinary gamboge; its color is, however, deep orange. A white crystalline compound, which when heated beyond 235° C. produced pyrocatechin, was found in it, and marked the point of difference between it and other varieties of gamboge. (*Rép. de Pharm.*, 1893, 193.)

Gamboge is said to be procured in Siam by breaking off the leaves and shoots of the tree; the juice, which is contained in ducts or latex vessels in the bark, issues in drops, and, being received in suitable vessels, gradually thickens, and at length becomes solid. Jamie of Singapore, states that incising the trunk and larger branches is often practised. The juice is frequently received into the hollow joints of the bamboo, and the water expelled by mild continuous heat. In this way the so-called pipe gamboge is formed, the contraction during drying causing the cylinders to be hollow. According to Beckett, Siam gamboge is obtained only from trees of not less than ten years of age and during the rainy months, from June to

October, by cutting long, spiral grooves into the bark and collecting in hollow bamboos the sap which trickles down in a viscous stream. (*Kew Bulletin*, 1895.)

The name *gummi gutta*, by which gamboge is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. The official title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. Gamboge was first brought to Europe by the Dutch, about the middle of the seventeenth century. We import it from Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports,—an evidence that it is originally derived from the same place.

Varieties.—The best gamboge is in cylindrical rolls, from one to three inches in diameter, sometimes hollow in the centre, sometimes flattened, often folded double, or agglutinated in masses so that the original form is not always easily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange color, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, slightly adhering to the surface. In this form the drug is sometimes called *pipe gamboge*. Another variety is imported under the name of *cake* or *lump gamboge*. It is in irregular masses of two or three pounds or more, often mixed with sticks and other impurities, containing many air-cells, less dense, less uniform in texture, and less brittle than the former variety, and breaking with a dull and splintery instead of a shining and conchoidal fracture. The worst specimens of this variety, as well as of the cylindrical, are sometimes called by the druggists *coarse gamboge*. They differ, however, from the preceding only in containing a greater amount of impurities. Indeed, it would appear from the experiments of Christison that all the commercial varieties of this drug have a common origin, and that cake or lump gamboge differs from the cylindrical only in the circumstance that the latter is the pure concrete juice, while to the former, farinaceous matter and other impurities have been added for the purpose of adulteration. The inferior kinds of gamboge may be known by their greater hardness and coarser fracture; by the brownish or grayish color of their broken surface, which is often marked with black spots; by their obvious impurities, and by the green color which their decoction, after cooling, gives with tincture of iodine (starch). When pure, the gum-resin is completely dissolved by the successive action of ether and water, so that the amount of residue left by any specimen treated in the manner just spoken of indicates approximately the measure of the adulteration.

Properties.—The official description is as follows: "In cylindrical pieces, usually hollow in the centre, of variable length, 2 to 5 Cm. in diameter, externally grayish orange-brown, longitudinally striate; fracture conchoidal, orange-red, waxy, and somewhat porous; inodorous; taste very acrid. Powder bright yellow, sternutatory, containing few or no starch grains. Not more than 25 percent. should be insoluble in alcohol; ash not more than 3 percent." *U. S.*

From the brilliancy of its color, gamboge is highly esteemed as a pigment. It has no odor, and little taste, but, after remaining a short time in the mouth, produces an acrid sensation in the fauces. Its sp. gr. is 1.221. "When solution of iodine is added to a cooled aqueous decoction, the color should not become distinctly green (absence of more than a trace of starch). When incinerated it should not yield more than 3 per cent. of ash." *Br.* It is a gum-resin, without volatile oil. Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. In one experiment, out of 100.8 parts he obtained 74.2 of resin, 21.8 of gum, and 4.8 of water. The gum is quite soluble in water, and of the variety denominated arabin. Flückiger, however, says that the gum is not identical with gum arabic, as its solution does not reddens litmus, and is not precipitated by neutral lead acetate, nor by ferric chloride, nor by sodium silicate or bichloride. By fusing purified gamboge resin with potassium hydroxide, Hlasiwetz and Barth (*Ann. Ch. Ph.*, 138, 61) obtained acetic and other acids of the same series, together with phloroglucin, $C_6H_5(OH)_3$, pyrotartaric acid, $C_6H_5O_4$, and isovitaminic acid, $COOH.C_6H_4.CH_2COOH$. Sassarini found gamboge to contain the following constituents: 1. Gum analogous to arabin. 2. Volatile oil, consisting of terpene and a camphor. 3. Isovitaminic and acetic acids. 4. A phenol ester. 5. Resin. 6. Methyl alcohol and some higher homologues. 7. A liquid having a fruity odor resembling aldehyde or acetone. He believes phloroglucin found by others to be a decomposition product. (*Ann. di Chim. Farm.*, 1897.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resin is very slowly deposited. It yields its resinous ingredient to alcohol, forming a golden-yellow tincture, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Ether dissolves about four-fifths of it, taking up only the resin. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; the solution when diluted deposits a yellow sediment. The color, acrimony, and medicinal power of gamboge are thought to reside in the resin. Hirschsohn gives a method for detecting gamboge in mixtures in *Ph. Z. R.*, xxiv. (*A. J. P.*, 1885.)

Uses.—Gamboge is a powerful, drastic, hydragogue cathartic, so very apt to produce

nausea and vomiting and much griping when given in the full dose that it is almost never employed except in combination with other cathartics. In large quantities it is capable of causing fatal effects, and death has resulted from a drachm. The full dose is from two to six grains (0.13 to 0.4 Gm.), which in cases of *tania* has been raised to ten or fifteen grains (0.65 to 1.0 Gm.). It may be given in pill or emulsion, or dissolved in an alkaline solution. In the dose of five grains (0.32 Gm.) the resin is said to produce copious watery stools, with little or no uneasiness. If this be the case, it is probable that, as it exists in the gum-resin, its purgative property is somewhat modified by the other ingredients.

Dose, two grains (0.13 Gm.).

The name of camphor has been applied to various concrete, white, odorous, volatile products, found in different aromatic plants, and resulting probably from chemical change in their volatile oil. But commercial camphor is derived exclusively from two plants, the *Camphora Officinarum* of Nees or *Laurus Camphora* of Linnæus, and the *Dryobalanops aromatica*; the former of which yields our official camphor, the latter, the Borneo or Baras camphor, a product much valued in the East, but unknown in the commerce of this country and of Europe.

Cinnamomum Camphora, *B. & T.* 222—*Camphora Officinarum*, Nees, *Laurin.* 88; Carson, *Illustr. of Med. Bot.*, ii. 29, pl. xxiv.—*Laurus Camphora*, L. Willd., *Sp. Plant.* ii. 478. The camphor tree is an evergreen which sometimes attains great size,¹ having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth, greenish bark. Its leaves, which stand alternately upon long foot-

stalks, are ovate-lanceolate, entire, smooth and shining, ribbed, of a bright yellowish-green color on their upper surface, paler on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a red berry, resembling that of the cinnamon. The camphor tree is a native of China, Japan, and adjacent portions of Eastern Asia, but is capable of cultivation in most sub-tropical countries, where the minimum winter temperature is not below 20° F., and the summers are warm. It thrives in Formosa, Madagascar, Argentina, Egypt, Canary Islands, Southern Europe, Southern Florida, Southern California, and is being cultivated in India and Ceylon. The chief obstacle to its cultivation seems to be the extreme slowness of growth of the tree, and the corresponding slowness of returns from the investment. For an account of cultivation in Florida see *D. C.*, Sept. 1902.

Although the leaves of the camphor tree when bruised have the odor of camphor the drug is obtained solely from the root, trunk, and branches by the process of sublimation. Only the older trees are employed; indeed it is said that a tree must be fifty years old before it should be considered available. The trees are marked in the forest after investigation by an expert, the lower part of the trunk, with roots, chopped up in small fragments, and some form of heat applied. In Japan, the chips are said to be placed with a little water in iron vessels, surmounted by earthenware capitals furnished with a lining of rice straw. A moderate heat is then applied, and the camphor, volatilized by the steam, rises into the capital, where it is condensed upon the straw. In China the comminuted plant is said to be first boiled with water until the camphor adheres to the stick used in stirring, when the strained liquor is allowed to cool, and the camphor which concretes, being alternated with layers of earth, is submitted to sublimation. In the island of Formosa, where the camphor tree abounds, the chips are heated in a rough still. This is usually composed of a furnace surmounted with a trough or similar rude vessel, which is protected by clay. In this reservoir the chips are placed, with water upon them, and a perforated board luted upon the top; on this are set earthenware pots. A fire having been lighted, steam rises through the chips and carries the camphor with it to deposit it in the pots. The crude camphor is taken to the towns in baskets and then put into large vats, with holes in the bottom, through which an oil escapes called *camphor oil*,² much used by the

¹A tree seen by Kämpfer, in Japan, in 1691, with a trunk 36 feet in circumference, was in the year 1826 described by Siebold as having a circumference of 50 feet.

²OIL OF CAMPHOR.—Two substances occur in commerce under the name of oil of camphor: the one derived from the *Cinnamomum Camphora*, known as the *Formosa* or *Japanese Oil of Camphor*, and formerly official under the name of *Oleum Camphoræ* in the *U. S. P.*; the other the product of *Dryobalanops aromatica*, the *East India oil of camphor*, not occurring in American and European commerce. The com-

Chinese for medicinal purposes. It is said that of recent years hydraulic pressure is largely substituted for drainage.

mercial oil of camphor, as found in our markets, is a colorless fluid or of a light yellowish-brown color, having a strong odor precisely like that of camphor, a bitterish camphoraceous taste, and a specific gravity, according to Wm. Procter, of 0.940. As described by Lillemand, the oil of the *Cinnamomum Camphora* is very fluid, scarcely colored, and of a strong odor of camphor. It acts strongly on polarized light, and is dextrogyrate. It has been considered to be simply a mixture of camphor, $C_{10}H_{16}O$, and a hydrocarbon, $C_{10}H_{18}$, but is in reality much more complex. Yoshida (A. J. P., 1886, p. 99) separated it into five portions, as follows: 0.2 per cent. boiling below $145^{\circ} C.$; 7 per cent. of a hydrocarbon boiling at $156^{\circ} C.$; 20 per cent. of a hydrocarbon boiling at 172° to $178^{\circ} C.$; 22.8 per cent. of camphor, boiling point $205^{\circ} C.$; 50 per cent. of an oxygenated oil boiling at 212° to $213^{\circ} C.$ The hydrocarbon boiling at $156^{\circ} C.$, Yoshida determined to be *terebinthene*, $C_{10}H_{16}$, which differs in physical respects, however, from the *terebinthene* of oil of turpentine. The hydrocarbon boiling at 172° to $173^{\circ} C.$ he found to have a pleasant lemon odor, and, he thinks, is identical with the *citrene* of lemon oil. To the oxygenated oil, which constitutes half of the crude oil, he gives the formula $C_{10}H_{16}O_2$, and calls it *camphorogenol*. Schimmel & Co. of Leipzig, have, since 1885, extracted *safrol* commercially from the Japanese oil of camphor, and they give a different account of its composition. They state (*Schim. Rep.*, 1888) that it contains *camphor*, *safrol*, *eugenol*, a *sesquiterpene*, $C_{15}H_{24}$, and possibly *terpinol*. They do not consider Yoshida's camphorogenol to be a distinct substance.

Within the last few years there has appeared in the American and English markets in considerable quantity an oil of camphor produced in Japan. It is imported in tin cans, and varies in tint from the colorless transparency of water, through pale straw and yellow, to deep black. The specific gravity varies from 0.898 in the colorless oil to 0.990 in the very dark. The oil seems to vary greatly in the amount of camphor it contains, much of it having nearly all the solid principle removed before exportation. The odor is distinctly camphoraceous, with a peculiarity that suggests the odor of *sassafras*. It is said by Peter MacEwan to differ from the Formosa oil in its behavior towards nitric acid. If half a drachm of the acid be allowed to act upon half a drachm of Japanese oil, and then diluted with half a drachm of water, a crimson color will be produced. The Formosa oil so treated yields a milky color with a scarcely perceptible green shade; hydrochloric acid gives with each oil a salmon color, more marked, however, with the Japanese oil. For further details, see P. J., vols. xv., xvi., and J. O. S., Oct. 1885. The oil is said to be used in Japan for the preparation of Chinese ink and varnishes, and for burning. As a diluent for artists' colors it is useful because its capacity for dissolving resins is greater than that of oil of turpentine and similar liquids.

The Formosa camphor oil industry, owing to onerous trade restrictions, has decreased greatly (*Journ. Soc. Chem. Ind.*, 1887, 391), while that of Japan has increased enormously. In 1885 the exportation from Japan was 225,200 kilos, in 1886, 537,700 kilos, and in 1887 much more; but on account of the failure of price the Japanese have consumed most of the oil they produce, the importation into the United States in 1892 having decreased to but a little more than one-fourth of what it formerly was.

The oil of camphor has properties similar to those of camphor, but more stimulant, and is especially applicable to affections of the stomach and bowels in which an anodyne and stimulant impression is indicated, as *flatulent colic* and *spasmodic cholera*. It may also be used externally, as a *rubefacient* and anodyne liniment, diluted with soap liniment, or olive oil, in *local rheumatism* and *neuralgic pains*, *bruises*, *sprains*, etc. The dose is two or three minims (0.12 to 0.2 Cc.).

The *Dryobalanops* oil of camphor is said to be found in trees too young to produce camphor, and is supposed to constitute the first stage in the development of this substance, as it occupies the cavities in the trunk which are afterwards filled with the camphor. The chief constituent of it is a peculiar volatile oil, which is termed *borneene*; it is isomeric with oil of turpentine, $C_{10}H_{18}$, and holds in solution borneol and resin. By fractional distillation this oil may be separated into two portions, the one more volatile than the other, but not differing in composition.

Commercial History.—The commerce of the world is supplied with camphor from China, Japan, and Formosa, the great bulk of the product coming from the latter island. After the annexation of Formosa by the Japanese, that Government, led by the unnecessary destruction of the camphor trees of the island, the inferiority of the camphor obtained, and the waste of the processes employed, and especially by the desire for revenue, made a governmental monopoly of the camphor trade which went into operation in 1900. The product obtained by the camphor gatherers is said to be taken by the government at a fixed price, about \$15.00 a picul (133 lbs.). From the first it was found necessary to afford military protection to the gatherers, from the abounding savage tribes, and during the Russo-Japanese war irregularities in this regard are said to have greatly diminished the product and to be the chief cause of the present high price of camphor. The camphor is sold by the Japanese government through a single London firm or company, Samuel Samuels, with sub-agencies at Hamburg, New York, and perhaps other cities. From these agencies refiners in different parts of the world buy it by contract for a year at a time. The statement freely made that camphor is sold at a fixed price by the Japanese government, is incorrect, and the extraordinary rise of camphor in price is shown by the fact that in Nov., 1895, the average wholesale price of refined camphor was 58 cents per pound; in Nov., 1900, 62.5 cents per pound; in Nov., 1905, 83 cents per pound. The importations of crude camphor were in 1902, 1,831,058 lbs., valued at \$576,405; in 1903, 2,508,420 lbs., valued at \$764,403; and in 1904, 2,819,883 lbs., valued at \$874,709.

There are two very distinct varieties of the crude camphor, namely—the Chinese and the Japanese,² the Japanese camphor being divided

² *Sumatra Camphor*. *Borneo Camphor*. *Dryobalanops Camphor*. *Bhimisalm Camphor*. *Baros Camphor*. *Borneol*.—This camphor is produced in the islands of Sumatra and Borneo, by *Dryobalanops aromatica*, Gaertn. (*D. Camphora*, Coleb.) This tree is very large, often exceeding one hundred feet in height, with a trunk six or seven feet in diameter, and ranks among the tallest and largest trees in India. (A. J. P., xlv. 329.) It is found in Sumatra and Borneo, and is abundant on the northwest coast of the former island. The camphor exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old. The only method of ascertaining whether a tree contains camphor is by incision. A party proceed through the forest, wounding the trees, till they find one which will answer their purpose; and hundreds may be examined before this object is attained. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed by means of sharp-pointed instruments. It is stated that the masses are sometimes as thick as a man's arm, and that the product of a medium-sized tree is nearly eleven pounds; of a large one, double that quantity. The trees which have been wounded and left standing often produce camphor seven or eight years afterwards. Ida Pfeiffer states, in her *Second Journey Round the World* (Am. ed., p. 183), that the camphor is also found in a concrete state under the bark and is swept down with long brooms. The whole tree is pervaded more or less by the cam-

into the Japanese camphor proper and the Formosa camphor. Of the two commercial varieties the Chinese comes in chests lined with lead, each containing about 130 pounds. It occurs in small grains or granular masses, of a dirty white color, frequently mixed with impurities. Japanese camphor (formerly known as *Dutch camphor* or "*tub camphor*" because it was exported through Batavia) is sent into market in tubs, covered with a peculiar matting, and in its general aspect resembles Chinese camphor. The value and purity of both Chinese and Japanese camphor vary greatly in different specimens, but recently much of the Chinese crude camphor has been whiter and cleaner than the Japanese. It is always small grained and yields on sublimation crystals much smaller than are obtained from Japanese camphor, and is therefore less esteemed. A dark inferior grade of camphor is also obtained in the United States from commercial oil of camphor.

Artificial Camphor.—Camphor can also be made artificially by the oxidation of *camphene*, $\text{C}_{10}\text{H}_{16}$, with chromium trioxide mixture. Camphene is obtained from either pinenehydro-

chloride (so-called artificial camphor) or from bornyl chloride by treatment with alcoholic potash, and is a solid crystalline mass, fusing at 49°C . In the patented process of Nathan Thurlow, camphor is made by submitting oil of turpentine to the action of anhydrous oxalic acid in steam-jacketed reaction tanks. The liquid mass, containing *pinyl oxalate* and *pinyl formate*, is then distilled in the presence of an alkali with live steam, the resultant products being camphor, Borneol camphor, and certain oily products, which are separated from one another and purified by a somewhat complicated process. It is stated that turpentine yields in this process from 25 to 35 per cent. of its weight, and that oil of lemon and other essential oils, and terpenes are obtained as secondary products. This artificial camphor is either optically inactive or has a very slight dextrorotation, but in general physical properties exactly resembles natural camphor. So far, however, it seems to be difficult to work the process upon a large scale and the artificial product has had no effect upon the general camphor market. Camphor can also be produced from isoborneol, by the action of oxidizing mixtures. The method patented in France, which is said to yield from 95 to 100 per cent. of camphor, consists in suspending ten kilogrammes of isoborneol in ten kilogrammes of benzol, and adding ten kilogrammes of potassium permanganate dissolved in one thousand liters of water, until the color of the permanganate is discharged. The camphor produced is separated by distillation and crystallized from petroleum benzin. (*Chem. Ztg.*, 28).

phor or the oil. The wood retains a fragrant odor, and, being, on this account less liable to the attacks of insects, is highly esteemed for carpenter work. Borneo camphor resembles in appearance ordinary camphor, but has, according to Christison, a specific gravity of 1.009, and sinks in water. Its odor is also distinctly different from that of camphor. It usually pulverizes without the addition of alcohol, is less volatile than ordinary camphor and does not crystallize in the interior of the bottles in which it is kept. It fuses at 206°C . and boils at 212°C .; is dextrogyrate; has a formula of $\text{C}_{15}\text{H}_{22}(\text{OH})$; and by the action of boiling nitric acid is converted into common camphor. It does not reach European commerce, being largely consumed in the Batta provinces, especially in funeral rites; and any that is exported is bought up at enormous prices for China, where it is preferred for embalming purposes on account of its being less volatile than the ordinary drug.

Borneo camphor is also produced in Johore, a province of the Malay peninsula, where it is sold in four qualities. The first is composed of transparent crystals, generally a quarter of an inch and upwards in length; the second of brown crystals, inferior in size; the third of powdery coherent and slightly colored grayish crystals, which resemble Japanese camphor; the fourth quality is brownish, pulverulent, and looks like sea shore sand. (See *P. J.*, xvii.)

Ngai camphor is yielded by the *Blumea balsamifera*, which occurs in India, China, Formosa, etc. The crude drug is known to the Chinese as *ngai-féu*, and when refined in Canton as *ngai-p'ien*. About ten thousand pounds annually are exported from Canton. The refined camphor in appearance, odor, hardness, specific gravity, and volatility agrees almost precisely with Borneo camphor. According to Plowman, it has the chemical composition of Borneo camphor, but differs from it in its alcoholic solution being lavogyrate, and in being converted by boiling nitric acid into a substance thought to be identical with the stereoptene of *Chrysanthemum Parthenium*, Pers.

The physiological action of Borneo and *Ngai camphor* and of artificial borneol has been studied by E. Stockman (*J. P.*, 1888), who finds that the action of the three substances is practically identical and closely resembles that of true camphor. He finds that these substances act as stimulants to the heart but that when the dose is sufficiently large there occurs a fall of blood pressure, apparently due to dilatation of the vessels; that in poisoning the respiration is always very much slowed, apparently by a centric action; that the convulsions which the drug produces are due to an influence upon the cerebral cortex; and that there is a lessening of the functional activity of the spinal cord and of the motor nerves. The results obtained by A. Lapin (*Med. Age*, 1894, xli.) with borneol, seem not to be discordant with those of Stockman, and show that in its proper dose the drug increases the energy of the heart, and that in frogs it is an especial motor nerve paralyzant.

Refined Camphor.—The process for refining camphor was first practised in Europe by the Venetians, who probably derived it from the Chinese. It was afterwards transferred to the Dutch, who long enjoyed a monopoly of this business; and it is only within recent years that the process has been generally known. It is now practised largely in this country, and the camphor refined in our domestic establishments is equal to any formerly imported. Crude camphor is mixed with about one-fiftieth of quick-lime, and exposed, in an iron vessel placed in a sand bath, to a gradually increasing heat, by which it is melted and ultimately converted into vapor, which condenses in a suitable receiver. Refined in this manner, it is usually in the form of large circular cakes, one or two inches thick, slightly convex on one side and concave on the other, and perforated in the centre. Much refined camphor comes into the market in the form of compressed blocks, this being especially true of camphor refined in Philadelphia and Japan. It is stated that in Japan the refining of camphor is done by the Government and also by individuals, the process being probably that employed in the Philadelphia laboratories, as the first refining of camphor was done in Japan by a man who had been thoroughly educated in these laboratories. Japanese refined camphor

occurs in rather thin, oblong cakes, enclosed in small tin boxes which have been hermetically sealed by paper pasted over their edges. Camphor is refined in Philadelphia as follows: The vessels in which the camphor is put are of cast iron, circular, from 12 to 15 inches or more in diameter, and 4 inches deep, with perpendicular sides, and a ledge at top, on which the cover rests. This consists of sheet iron, with a hole through the centre about an inch in diameter, over which a small hollow cone of sheet iron is placed loosely. The crude camphor mixed with the lime, the object of which is said to be to combine with the moisture present, which interferes with the due solidification of the camphor vapor, is placed in the iron vessels described, of which from 20 to 50 are arranged in a long sand bath. Heat is then applied until the camphor melts, after which the temperature is kept as nearly uniform as possible, so that the vaporization may take place regularly, without violent ebullition. The vapor condenses on the lower surface of the lid, and care is taken, by the occasional removal of the iron cone, and clearing of the opening by means of a knife, to allow the escape of any accidental excess of the vapor.

Properties.—"White, translucent masses, of a tough consistence and a crystalline structure, readily pulverizable in the presence of a little alcohol, ether, or chloroform; having a penetrating, characteristic odor, and a pungent, aromatic taste. Specific gravity: 0.990 at 25° C. (77° F.). It is optically active, being dextrogyrate. Very sparingly soluble in water, but readily soluble in alcohol, ether, chloroform, carbon disulphide, petroleum benzin, and in fixed and volatile oils. When Camphor is triturated, in about molecular proportions, with menthol, thymol, phenol, or hydrated chloral, liquefaction ensues. It melts at 175° C. (347° F.), boils at 204° C. (399.2° F.), and is inflammable, burning with a luminous, smoky flame. On exposure to the air, it evaporates more or less rapidly at ordinary temperatures, and, when moderately heated, it sublimates without leaving a residue. If a small piece of Camphor be dropped into a small porcelain dish, the latter placed in a larger dish, and a clean beaker moistened on the inner surface with distilled water be inverted over the smaller dish immediately after igniting the Camphor, a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water, and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate T.S. (absence of chlorinated products)." *U. S.* Camphor has a peculiar, strong, penetrating, fragrant odor, and a bitter, pungent taste, with a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, brittle, and yet possessed of a tenacity which renders its reduction to a fine powder very difficult, unless its cohesion be overcome by the addition of a minute proportion of alco-

hol, ether, chloroform, glycerin, essential or fatty oils, or other volatile liquid for which it has an affinity. It may be obtained in powder by pulverizing with an equal weight of sugar, by precipitating the tincture with water, or by grating and afterwards sifting it, or, by sublimation. A still better plan is to dissolve camphor in one and a half parts of alcohol, and pour this solution with stirring into four parts of water. Collect the precipitate, wash with water, and dry. By noting the quantity of camphor used, the amount left dissolved in the diluted alcohol can be calculated, and this solution used in making tincture. The fracture of camphor is shining, and its texture crystalline. Its sp. gr. varies from 0.9857 to 0.996. When thrown in small fragments upon water, it assumes singular circulatory movements, which cease upon the addition of a drop of oil; and this property has been applied to the detection of grease in liquids, a very small proportion of which is sufficient to prevent the movements. Its volatility is so great that, even at ordinary temperatures, it is wholly dissipated if left exposed to the air. When it is confined in bottles, the vapor condenses on the inner surface, and, in large bottles partially filled, sometimes forms, after long standing, large and beautiful crystals. It melts at 175° C. (347° F.), boils at 204° C. (399.2° F.), and, in closed vessels, sublimates unchanged.

When allowed to concretize slowly from the state of vapor, it assumes the form of hexagonal plates. It is not altered by air and light. It readily takes fire, burning with a brilliant flame, with much smoke, and without residue. Water triturated with camphor dissolves, according to Berzelius, not more than a 1000th part; which, however, is sufficient to impart a decided odor and taste to the solvent. By the intervention of sugar or magnesia a much larger proportion is dissolved. (See *Aqua Camphoræ*.) Carbon dioxide increases the solvent power of water, as also does the spirit of nitrous ether. Ordinary alcohol will take up 75 per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states that 100 parts of alcohol, of the sp. gr. 0.806, dissolve 120 parts at 10° C. (50° F.). It is soluble without change in ether, the volatile and fixed oils, strong acetic acid, and diluted mineral acids, and is extremely soluble in chloroform. "It is soluble in about 700 parts of water, in about 1 part of alcohol (90 per cent.), in one quarter part of chloroform, and in 4 parts of olive oil; very soluble in ether." *Br.* Nitric acid on prolonged boiling with camphor oxidizes it into camphoric acid, $C_{10}H_{16}O_4$ (see page 25), and camphoronic acid, $C_6H_{14}O_6$. Schwanert's camphresinic acid, $C_{10}H_{14}O_{12}$, is, according to Kachler, a mixture of these two. Sulphuric acid in the proportion of ten parts to one gives, when heated with camphor, an oil isomeric with camphor, boiling at 200° C. (392° F.), and yielding a solid camphor when distilled repeatedly over potassium hydroxide.

Sulphuric acid in the proportion of four to one with camphor, gives, according to Chautard, a volatile product which he calls *camphrene*, and to which Schwanert gives the formula $C_8H_{14}O$. Kachler (*Ann. Ch. Ph.*, 164, p. 90) considers, however, that camphrene is only *phorone* (a condensation product of acetone) with slight impurities. Alcoholic potassium hydroxide solution heated with camphor gives a derivative called *campholic acid*, $C_{10}H_{18}O_2$, a white solid, fusing at $95^\circ C.$ ($203^\circ F.$), and boiling at $250^\circ C.$ ($482^\circ F.$). Resins unite with camphor, forming a soft tenacious mass, in which the odor of the camphor is sometimes almost extinguished, and frequently diminished; and a similar softening effect results when it is triturated with the concrete oils. Exposed to a strong heat, in close vessels, camphor is resolved into carbonic acid gas and hydrocarbons, among which cymol is especially to be recognized.

Camphor, $C_{10}H_{16}O$, and borneol, $C_{10}H_{18}O$, are classified together as belonging to the group called in general *camphors*, which occur with the *terpenes* or essential oils, $C_{10}H_{16}$, and are to be considered as oxidation products of these latter.

Borneol is an alcohol, yielding esters when heated to about $200^\circ C.$ ($392^\circ F.$) with organic acids. It is a secondary alcohol, and therefore contains the group $CH.OH$ linked to a more complex group. Secondary alcohols by oxidation yield *ketones*, by the change of the $CH.OH$ group to CO . Common camphor bears this relation to borneol, and is therefore considered as a ketone, and can be formed from borneol by the action of mild oxidizing agents. The action of metallic sodium, on the other hand, upon common camphor, $C_{10}H_{16}O$, yields borneol, $C_{10}H_{18}O$.

Genuine camphor is said to be sometimes adulterated with the artificial, which may be detected by the action of ammonia upon its alcoholic solution, causing a flocculent precipitate, which does not redissolve, and the quantity of which is proportionate to that of the artificial product in any mixture of the two. (*A. J. P.*, xxxiv. 189.) As a means of distinguishing camphor from the artificial camphor resulting from the reaction between the oil of turpentine and hydrochloric acid, J. W. Bailey recommends that a drop of alcohol, holding in solution a little of the camphor to be tested be allowed to evaporate on the slide of a microscope. The crystals then formed produce with polarized light, beautiful colors, if of natural camphor, but not, if of the artificial. (*Neues Repertorium*, xvi. 763, 1867.)

Uses.—Camphor does not seem to have been known to the ancient Greeks and Romans. Europe probably derived it from the Arabians, by whom it was employed as a refrigerant. The local action of camphor is that of an irritant, with probably a benumbing influence upon the peripheral nerves of the mucous membrane. It is readily absorbed, and is finally eliminated from the kidneys, chiefly in the form

of campho-glycuronic acid. When taken in moderate dose it produces in health a feeling of warmth in the stomach, some increase in the frequency, the force, and the fullness of the pulse, and a slight mental exhilaration. After larger doses there are lassitude, decrease in the frequency of the pulse, and giddiness, preceded, it may be, by a short period of excitement. The symptoms produced by poisonous doses are: faintness, headache, vertigo, confusion of ideas, burning pain in the stomach, delirium, violent convulsions, insensibility, general paralysis; a pulse generally small, but sometimes accelerated and sometimes lowered in number; a skin cool, pale, or livid, generally bedewed with sweat. Sudden unconsciousness, with or without convulsions, has been in some instances the first manifestation of the action of the poison, and of course in any individual case many of the symptoms detailed above may be wanting. Camphor has an action upon the cerebral cortex by virtue of which when in moderate dose it has some calmative influence, and when in toxic dose is capable of causing coma and convulsions. The therapeutic dose has no perceptible influence upon the spinal cord, although there is some physiological reason to believe that in certain doses the drug does stimulate the motor cells; in toxic doses there is depression of the motor cord. The drug acts as a stimulant of moderate power upon the respiratory centres, and also upon the cardiac muscle, but does not distinctly and consistently elevate the blood pressure because of the dilatation of the blood vessels which it produces, by both centric and peripheral action. It is used in practical medicine as an antispasmodic in various hysterical conditions, in nervous headaches, *dyspnoea*, etc. At one time it was supposed to have a distinct influence upon the sexual organs, and was used both as an aphrodisiac and as an anaphrodisiac, but is at present rarely employed in sexual conditions. As a cardiac stimulant it has been largely used, especially in Germany, in sudden heart failure and in the profound adynamia of acute endocarditis, typhoid fever, pneumonia, etc., frequently with happy effect. For this purpose it must be employed hypodermically, preferably dissolved in olive oil. For hypodermic use the German Pharmacopœia recognizes *Oleum camphoratum* (which should not be confounded with *Linimentum Camphoræ* of the U. S. Pharmacopœia), the oil is made by dissolving one part of camphor in nine parts of olive oil. According to Schilling, as much as thirty grains a day of the camphor may be thus administered without disagreeable results. As a local remedy, camphor is of value in all forms of *serous diarrhoea*, allaying intestinal pain and checking intestinal secretions. It is largely employed as a local application which is at once stimulant and calmative in *rheumatic affections*, in *sprains*, *bruises*, and like injuries; camphor is largely used in liniments. It may be administered in pill but pre-

ferably in capsule, but when very large doses are given it is best administered in emulsion, as in this form it produces as mild gastric irritation as possible.

Camphor water of the U. S. Pharmacopœia is an excellent but feeble preparation. The spirit of camphor may be given in milk or even in water, although under the latter circumstances it is apt to adhere to the sides of the vessel or of the spoon. An excellent method of administration is afforded by an emulsion made by rubbing up the camphor with mucilage of acacia and water. As camphor is freely soluble in chloroform, when it is desired to give the two remedies together the camphor may be dissolved in the chloroform. There is no known antidote to camphor, and in poisoning by it, after evacuation of the stomach and bowels, the symptoms must be met as they arise.

Dose, two to five grains (0.13 to 0.32 Gm.).

CAMPHORA MONOBROMATA. U. S.

MONOBROMATED CAMPHOR

(căm'pho-ră mŏn-ô-brô-mă'tă)

$C_{10}H_{15}BrO = 229.34$

"A substitution product of camphor [$C_{10}H_{15}Br.CO$]." *U. S.*

Bromated Camphor, Brominated Camphor, Brom-camphor, Bromo-camphor; Camphre Monobromé, *Fr. Cod.*; Monobrom Camphor, Bromkampher Kampher-monobromid, *G.*; Camfora monobromata, *It.*; Alcanfor monobromado, Bromuro de alcanfor, *Sp.*

This substance was discovered in 1861 by Th. Swarts, who prepared it by heating dibromide of camphor in a sealed tube to 100° C. It may also be made by heating bromine and camphor in the proper chemical proportions for three hours in a sealed tube, on a water bath. The crystalline mass is washed with water, recrystallized from alcohol after treatment with animal charcoal, washed with an alcoholic solution of potassium hydroxide, then with much water, and finally recrystallized from a mixture of alcohol and ether. It is very easy to prepare the monobromide on a small scale in this way. There is, however, at all times a very great pressure upon the inside of the tube, and the attempt to practise the method upon a large scale is very likely to result in shattering the

tubes. This has led to numerous experiments as to the best method of preparing it. For methods of preparing bromocamphor and allied products, see *Chem. News*, 1896, 208. Maisch's method is as follows: Introduce 4 oz. of bromine gradually into a retort in which 13 oz. of camphor have been previously placed. In 15 or 20 minutes a brisk reaction will commence. When this subsides, 8 or 9 oz. more of bromine are to be poured in, in four portions waiting after each addition until the reaction ceases. The liquid in the retort is now to be heated to about 132° C. (270° F.), then cooled, and sufficient petroleum benzin added to dissolve the crystalline mass. The crystals which are formed on cooling may be purified by recrystallization from benzin or hot alcohol. (*A. J. P.*, 1872, 339.) Various modifications of this process have been proposed. J. U. Lloyd (*A. J. P.*, April, 1875) directs the addition of water to the camphor and bromine in the retort, and boils the mixture for two hours, or until all the water is evaporated. Then the contents are poured into a dish and treated with warm alcohol, and allowed to crystallize, the mother liquor being drained off and the product recrystallized from hot alcohol. C. C. Keller (*S. W. P.*, 1880, p. 50) uses chloroform (instead of water, as proposed by Lloyd) with the camphor and bromine, and washes the crystals with absolute alcohol, crystallizing them finally from an ethereal solution. 300 parts of camphor yield 340 parts of monobromated camphor, the theoretical yield being about 456 parts.

Properties.—"Colorless, prismatic needles or scales, having a mild but characteristic camphoraceous odor and taste, permanent in the air, unaffected by light, and neutral to litmus paper. Almost insoluble in water; freely soluble in alcohol, ether, chloroform, hot petroleum benzin, and fixed and volatile oils; slightly soluble in glycerin; it is also soluble, without decomposition, in cold, concentrated sulphuric acid, from which it separates again unaltered, when the solution is poured into water. It melts at 76° C. (168.8° F.), and sublimes at a slightly higher temperature. At 274° C. (525.2° F.) it boils without decomposition, and is finally volatilized without leaving a residue. If a few crystals of Monobromated Camphor be fused in a dry test-tube with metallic sodium, the residue dissolved in water and the solution acidulated with nitric acid, a copious, faintly yellowish precipitate should be produced upon the addition of silver nitrate T.S." *U. S.*

Uses.—Monobromated camphor was first proposed as a medicine by Deneffe, and has been used as a nerve sedative in *delirium tremens*, *hysteria*, *convulsive irritation* of teething, *sleeplessness*, etc. According to the experiments of Bourneville (*Prog. Med.*, 1874) and of Lawson, it produces in mammals muscular weakness, passing into paralysis, very decided progressive reduction of temperature, decrease in the respiration rate, sleep passing into stupor, and finally death. Bourneville states

that the vessels of the ear and eyelids in the rabbit are contracted. Its therapeutic action resembles, but is not identical with, that of other bromides; in the experience of H. C. Wood, it has seemed to be of value in *spermatorrhæa*. It is not safe to give it too freely, as in some cases its ingestion has been followed by epileptiform convulsions. The emulsion may be made by dissolving it in six times its weight of expressed oil of almonds, and then forming an emulsion with gum and water in the usual manner.¹

Dose, two to five grains (0.13 to 0.32 Gm.) repeated as required.

CANNABIS INDICA. U. S., Br.

INDIAN CANNABIS [Indian Hemp]

(cān'na-bīs in'di-çə)

"The dried flowering tops of the pistillate plants of *Cannabis sativa* Linné (Fam. *Moraceæ*), grown in the East Indies and gathered while the fruits are yet undeveloped, and carrying the whole of their natural resin." *U. S.* "The dried flowering or fruiting tops of the female plant of *Cannabis sativa*, Linn., grown in India; from which the resin has not been removed." *Br.*

Hemp, Indian Hemp; *Herba Cannabis Indicæ*; Chanvre, *Fr. Cod.*; Chanvre de l'Inde, *Fr.*; Indischer Hanf, *G.*; Cañamo, *Sp.*

Cannabis sativa, Linn., *Sp. Plant.* 1457; Griffith, *Med. Bot.*, p. 572; *B. & T.* 231.—Hemp is an annual plant, from four to eight feet or more in height, with an erect, branching, angular stem. The leaves are alternate or opposite, on long, lax footstalks, roughish, and digitate, with linear-lanceolate, serrated segments. The stipules are subulate. The flowers are axillary; the male in long, branched, drooping racemes; the female in erect, simple spikes. The stamens are five, with long pendulous anthers; the pistils two, with long, filiform, glandular stigmas. The fruit is ovate and one-seeded. The whole plant is covered with a fine pubescence, scarcely visible to the naked eye, and somewhat viscid to the touch. The hemp plant of India, from which the drug is derived, has been considered by some as a distinct species, and named *Cannabis indica*; but the most observant botanists, upon comparing it with our cultivated plant, have been unable to discover any specific difference. It is now, therefore, regarded merely as a variety, and is distinguished by the epithet *indica*. Pereira states that in the female plant the flowers are somewhat more crowded than in the common hemp, but that the male plants in the two varieties are in all respects the same.

¹ *Elixir of Monobromated Camphor* is proposed by Munday (*P. J.*, March 3, 1877). Monobromated camphor 3 parts, alcohol (90 per cent.) 120 parts, orange-flower water 80 parts, glycerin 100 parts. Mix the alcohol and glycerin; dissolve the monobromated camphor by the use of a gentle heat, and add the orange-flower water. It contains 1 per cent. of monobromated camphor.

C. sativa is a native of the Caucasus, Persia, and the hilly regions in Northern India. It is cultivated in many parts of Europe and Asia, and largely in our Western States. It is from the Indian variety exclusively that the medicine was formerly obtained, the heat of the climate in Hindostan apparently favoring the development of its active principle.² H. C. Wood, having obtained a parcel of the male plant of *C. americana* (*C. sativa*) from Kentucky, made an alcoholic extract of the leaves and tops, and, upon trying it on the system, found it effective in less than a grain, and, having inadvertently taken too large a dose, experienced effects which left no doubt of the powers of the medicine, and of the identity of its influence with that of the Indian plant. How far the female tops might have the same effect is left uncertain; but if we are to judge from analogy with the Indian plant, they would be preferable to the male. (*Proc. Am. Philos. Soc.*, vol. xi. p. 226.) The results obtained by H. C. Wood were so decisive that at the 1880 revision of our Pharmacopœia the American plant was recognized; but in 1890 it was dropped as *C. americana*.

Cannabis indica from the North of France, also from Uganda, Africa, has appeared in London. According to W. E. Dixon, neither of the above varieties is nearly so active as is the Indian drug. (*P. J.*, April, 1905.)

The seeds, though not now official, have been used in medicine. They are about the eighth of an inch long, roundish-ovate, somewhat compressed, of a shining ash-gray color, and of a disagreeable, oily, sweetish taste. They yield by expression about 20 per cent. of a fixed oil, which has the drying property, and is used in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water form an emulsion, which may be used advantageously in inflammations of the mucous membrane, though without narcotic properties. The seeds are much used as food for birds, as they are fond of them. They are generally believed to be in no degree poisonous; but Michaud relates the case of a child in whom

² On a visit to the botanical garden of Edinburgh, in the autumn of 1860, George B. Wood saw a full grown specimen of *Cannabis sativa*, and was surprised to find that it was only about four feet high, had little or no odor, and was scarcely adhesive when handled. If this is the general character of the hemp plant in the north of Europe, it is not surprising that it should be destitute of the medicinal properties of the Indian plant. In Philadelphia the plant attains a height usually of six or eight feet, has a decided narcotic odor, and exudes so much of its peculiar resin as to be very adhesive to the fingers. On this occasion Christison informed George B. Wood, from information he had received from India, that the plant there cultivated in the hot plains does not yield hashish satisfactorily, but that this product is chiefly if not exclusively obtained from it in the hilly regions. He said, moreover, that the story of the natives running through the hemp fields and collecting the resin on their clothing, from which it is afterwards scraped, is, if not quite untrue, at least apocryphal. He had been informed that the real mode of gathering it is to rub the hemp tops between the hands and, when the palms and fingers are sufficiently loaded with the resin, to scrape it off. It is possible, however, that different methods may be followed in different localities.

serious symptoms of narcotic poisoning occurred after taking a certain quantity of them. It is probable that some of the fruit eaten by the child was unripe, as in this state it would be more likely to partake of the peculiar qualities of the plant. (*Ann. Thér.*, 1860.)

In Hindostan, Persia, and other parts of the East, hemp has long been habitually employed as an intoxicating agent. The parts are the tops of the plant, and a resinous product obtained from it. *Bhang*, is the selected, dried and powdered leaves. *Ganjah* or *gunjah* is the tops of cultivated female plants, cut directly after flowering, and formed into round or flat bundles from two to four feet long by three inches in diameter.¹ It is stated that in the province of Bengal great care is taken to eradicate the male plants from the fields before fertilization of the female, and that thereby the yield and quality of the resin is greatly increased. In Bombay this matter is commonly neglected, so that Bengal ganjah is much superior to Bombay ganjah. It is recognized in India that ganjah rapidly deteriorates on keeping, that which is one year old being not more than one-quarter as potent as the fresh drug, while two year old ganjah is practically inert and is required by the Indian government to be burned in the presence of excise officers. It is probable, however, that much old ganjah finds its way into the markets of the world. All importations of ganjah or hemp from India should be made directly after the harvesting of the new crop in April or May, and the extract should be prepared at once and kept in hermetically sealed jars. There is on the surface of the plant a resinous exudation to which it owes its stickiness. Men clothed in leather or rawhides are said to run through the hemp fields, brushing forcibly against the plants, thus separating the resin, which is subsequently scraped from their dress and formed into balls. These balls, and also masses formed out of resin mechanically separated from gunjah bundles are called *churrus*. This is the *hashish* or *hasheesh* of the Arabs.

Hashish is also produced in considerable quantities in Persia by rolling and rubbing the flowers, stalks and leaves of hemp on rough woolen carpets and subsequently scraping off with a knife and making into balls or sticks the adherent resinous substance. The carpets are afterwards washed with water and the extract obtained by evaporation sold at a low price. The dose for smoking of the best hashish is said to be one-fourth to one grain (0.016 to 0.065 Gm.). The fanatics are affirmed to be generally hashish devotees.

The dealing in hashish in India is said to be a Government monopoly, and a very heavy license is required for the right to even purchase it in quantity. The importation of it into Egypt is so strongly interdicted that the mere possession of it is a penal offence; we found it,

however, readily procurable. It is said to be brought into the country in pigs' bladders, in the Indo-European steamers, and thrown out at night during the passage into the Suez canal, to be picked up by the boats of confederates. Notwithstanding the Governmental interdiction, it is largely used by smoking in Egypt, as an intoxicant. The statement of W. E. Dixon (*B. M. J.*, Nov. 1899) that the inhalations of hemp smoke produces great exhilaration and causes muscular fatigue to disappear for the time being is undoubtedly correct, but his further belief that the habit is not apt to grow upon the hemp votary is more doubtful.

Momea or *mimea* is a hemp preparation said to be made in Thibet with human fat. From gunjah the Messrs. Smith of Edinburgh, obtained a purer resin by the following process. Bruised gunjah is digested, first in successive portions of warm water, until the expressed liquid comes away colorless; and afterwards for two days, with a moderate heat, in a solution of sodium carbonate, containing one part of the salt for two of the dried herb. It is then expressed, washed, dried, and exhausted by percolation with alcohol. The tincture, after being agitated with milk of lime containing one part of the earth for twelve of the gunjah used, is filtered; the lime is precipitated by sulphuric acid; the filtered liquor is agitated with animal charcoal, and again filtered; most of the alcohol is distilled off, and to the residue twice its weight of water is added; the liquor is then allowed to evaporate gradually; and, finally, the resin is washed with fresh water until it ceases to impart a sour or bitter taste to the liquid, and is then dried in thin layers. Thus obtained, it retains the odor and taste of the gunjah, which yields from 6 to 7 per cent. of it.

Properties.—Fresh hemp has a peculiar narcotic odor, which is said to be capable of producing vertigo, headache, and a species of intoxication. It is much less in the dried tops, which have a feeble bitterish taste. According to Royle, *churrus* is, when pure, of a blackish-gray, blackish-green, or dirty olive color, of a fragrant and narcotic odor, and a slightly warm, bitterish, and acrid taste. The Indian hemp is officially described as "in dark green or more or less brownish compressed masses, consisting of the densely paniculate branchlets, about 5 Cm. or more in length, and the inflorescence more or less agglutinated with a resinous exudation; commonly with a few undeveloped digitate leaves of one or more linear-lanceolate leaflets; clothed with numerous sheathing, pointed bracts, each containing two small mature but unfertilized pistillate flowers; odor agreeably narcotic; taste characteristic. In the powder few or no pollen grains or stone-cells should be present." *U. S.* "The fruit is one-seeded and supported by an ovate-lanceolate bract. Both leaves and bracts bear external oleo-resin glands and one-celled curved hairs, the bases of which are enlarged and contain

¹ For detailed description see *P. J.*, lxi. 1902, p. 129.

cystoliths." Br. For a histological description of the leaf by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1897, 569.

Indian churru or *hasheesh* is a hard resinous mass of a greenish-gray color, containing much gritty earth, and, as it occurs in Egypt, of a feeble, hemp-like odor and taste. Schlessinger found in the leaves a bitter substance, chlorophyll, green resinous extractive, coloring matter, gummy extract, extractive, albumen, lignin, and salts. The plant also contains volatile oil in very small proportion, which probably has narcotic properties. The resin obtained by T. & H. Smith of Edinburgh, in 1846, has been thought to be the active principle, and received the name of *cannabin*. By repeated distillation of the same portion of water from relatively large quantities of hemp renewed at each distillation, M. J. Personne obtained a volatile oil, of a stupefying odor, and an action on the system such as to dispose him to think that it was the active principle of the plant. As the water distilled was strongly alkaline, he supposed that his volatile principle might be a new alkaloid; but the alkaline reaction was found to depend on ammonia; and the liquid obtained proved to be a volatile oil, lighter than water, of a deep amber color, a strong odor of hemp, and composed of two distinct oils, one colorless, with the formula $C_{18}H_{20}$, the other a hydride of the first, $C_{18}H_{22}$, which was solid, and separates from alcohol in plate-like crystals. For the former Personne proposes the name of *cannabene*. It is affirmed that when this is inhaled, or taken into the stomach, a singular excitement is felt throughout the system, followed by a depression, sometimes amounting to syncope, with hallucinations which are generally disagreeable, but an action on the whole slighter and more fugitive than that of the resin. The various substances of alkaloidal nature that have been described by different investigators as found in Indian hemp are now recognized as due to decomposition products of *choline*, which was identified as present by Jahns (*P. J.* (3), 17, 1049). *Cannabindon*, $C_{20}H_{30}O$, is a dark red syrupy liquid obtained by Kobert (*Chem. Ztg.*, 1894, 741) from *Cannabis Indica*; it is soluble in alcohol, ether and oils; it is affirmed to be narcotic in doses of from half a grain to two grains (0.032 to 0.13 Gm.). As a result of a reinvestigation of *charras* (*churru*) from Indian hemp, Wood, Spivey, and Easterfield (*J. Chem. S.*, vol. lxi. 539) have found the following principles: 1, a *terpene*, boiling between 150° and 180° C.; 2, a *sesquiterpene*, boiling at 258° to 259° C.; 3, a *crystalline paraffin* of probable formula $C_{20}H_{40}$, melting at 63.5° C.; and 4, a *red oil*, boiling at 265° to 270° C. under a pressure of 20 Mm., to which they give the name *cannabinol*, and the formula $C_{18}H_{22}O_2$. This latter constituent they consider the only active ingredient. It is probably the same substance as the dark red syrup of Kobert, mentioned above under the name

cannabindon. The authors found that *cannabinol* readily underwent superficial oxidation, at the same time losing its toxic activity. Famuleuer and Lyons (*A. Pharm.*, 1904) believe that the only reliable preparation of *Cannabis* is a fluidextract made from the *fresh* drug. I. Roux (*A. Pharm.*, 1887), has experimented upon extracts made by treating purified extract of hemp with petroleum benzin and ether. The ether extract produced insignificant results. The petroleum extract was excitant and convulsivant. The alcoholic extract was a feeble narcotic. At the present time (1905) no characteristic alkaloid is believed to be present; the volatile oil, found in small quantity, is not the active principle. The resin "*cannabin*" of which *cannabinol* is the chief constituent, appears to be active. Fränkel (*A. E. P. P.*, 1903, p. 266) claims to have isolated the active principle of hashish as a pure and chemically well defined body. It has the formula $C_{18}H_{20}O_2$, and is a phenol-aldehyde. It is of a pale yellow color and of a thick consistency. When heated it becomes quite fluid and distils at 215° C. under a pressure of 0.5 Mm. It oxidizes in the air, acquiring a brown tint. It responds to Millon's reaction, and can be acetylated, showing thus its phenol character. Fränkel proposes that the name *cannabinol* be given to it and that the term *pseudo-cannabinol* be given to the inactive substance of Wood, Spivey and Easterfield.

Uses.—Extract of hemp is a powerful narcotic, causing exhilaration, intoxication, delirious hallucinations, and, in its subsequent action, drowsiness and stupor, with little effect upon the circulation. It is asserted also to act as a decided aphrodisiac, to increase the appetite, and occasionally to induce the cataleptic state. In overdoses it may produce poisonous effects. In morbid states of the system it has been found to cause sleep, to allay spasm, to compose nervous disquietude, and to relieve pain. In these respects it resembles opium; but it differs from that narcotic in not diminishing the appetite, checking the secretions, or constipating the bowels. It is much less certain in its effects, but may sometimes be preferably employed, when opium is contra-indicated by its nauseating or constipating effects, or its disposition to produce headache, and to check the bronchial secretion. The complaints in which it has been specially recommended are *neuralgia*, *gout*, *rheumatism*, *tetanus*, *hydrophobia*, *epidemic cholera*, *convulsions*, *chorea*, *hysteria*, *mental depression*, *delirium tremens*, *insanity*, and *uterine hemorrhage*. Alexander Christison of Edinburgh, affirms that it has the property of hastening and increasing the contractions of the uterus in delivery, and has employed it with advantage for this purpose. It acts very quickly, and without anæsthetic effect. It appears, however, to exert this influence only in a certain proportion of cases. (*Ed. Month. Journ. of Med. Sci.*, xiii. 117; xv. 124.) According to C. R. Marshall (*L. L.*, i., 1897; also *J. A. M. A.*,

Oct. 1898), cannabinol acts as a powerful hypnotic upon dogs and cats, producing also ataxia and other evidences of action upon the nerve centres. Its influence upon the circulation was found to be very feeble, though excessive doses reduced the pulse rate. In man, doses of from one and a half to two grains of cannabinol produced very active intoxication, with symptoms similar to those caused by cannabis indica. The strength of the extract varies much as found in commerce, and therefore no definite dose can be fixed. When it is of good quality, half a grain or a grain (0.032 to 0.065 Gm.), will affect the system, while some apparently good extracts are practically inert. The proper plan is to begin with one-quarter grain (0.016 Gm.), repeated at intervals of two, three, or four hours, and gradually increased until its influence is felt, and the strength of the parcel employed is thus ascertained. Afterwards the dose should be regulated by the ascertained strength; but, should a new parcel be employed, the same caution must be observed as to the commencing dose. The Br. tincture is prepared by dissolving an ounce of the extract in a pint (Imp. meas.) of alcohol. A dose of this, equivalent to a grain of the extract, is about twenty minims (1.3 Cc.), or forty drops. The inertness of much of the commercial extract Marshall believes to be due to the proneness of cannabinol to undergo oxidation. Of the terpenes of cannabis indica, Marshall took as high as eight minims (0.5 Cc.) without effect.

Dose, of Indian cannabis, one to two grains (0.065 to 0.13 Gm.).

Off. Prep.—Extractum Cannabis Indicæ, U. S., Br.; Fluidextractum Cannabis Indicæ, U. S.; Tinctura Cannabis Indicæ, U. S., Br. (from extract).

CANTHARIS. U. S., Br.

CANTHARIDES [Blistering Flies, Spanish Flies]

(căn'thə-ris)

"The beetle, *Cantharis vesicatoria* (Linné) De Geer, thoroughly dried at a temperature not exceeding 40° C. (104° F.)." U. S. "The dried beetle, *Cantharis vesicatoria*, Latr." Br.

Muscæ Hispanicæ: Cantharide, Fr. Cod.; Cantharides, P. G.; Spanische Fliegen, Cantharide, Canthariden, G.; Cantaride, Cantarella, Mosca di Spagna, It.; Cantaridina, Sp.

The Br. Add. under the name of *Mylabris phalerata*, Pallas, but also allows the use in the Colonies of other species of the genus, provided that they yield a similar proportion of cantharidin.¹

The term *Cantharis* was employed by the ancient Greek writers to designate many coleopterous insects or beetles. Linnaeus gave the title to a genus not including the official blistering insect, and placed this in the genus *Meloë*, which, however, has been since divided into several genera. Geoffrey made the Spanish fly (beetle) the prototype of a new genus, *Cantharis*, substituting *Cicindela* as the title of the Linnæan genus. Fabricius altered the arrangement of Geoffrey, and substituted *Lytta* for *Cantharis* as the generic name. The former was adopted by the London College, and at one time was in extensive use; but, the latter, having been restored by Latreille, is now recognized in the British and U. S. Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe, corresponding very nearly with the Linnæan genus *Meloë*, and distinguished by the title *Cantharidæ*. This tribe he divided into eleven genera, among which is *Cantharis*. Two others of these genera, *Meloë* properly so called, and *Mylabris*, have been employed as vesicatories. *Mylabris cichorii* is thought to be one of the insects described by Pliny and Dioscorides under the name of cantharides, and is to this day employed in Italy, Greece, the Levant, and Egypt; and another species, *M. pustulata*, is used for the same purpose in China. W. R. Warner has found 500 parts of *M. cichorii* to yield 2.13 parts of cantharidin, which somewhat exceeds the yield of Spanish flies (*A. J. P.*, xxviii. 195); and R. Wolff has obtained by ethereal extraction more than 4 parts of cantharidin in 500 of the *Lytta aspersa* of Buenos Ayres. The *M. cichorii* has been recently imported to some extent under the name of *Chinese blistering fly*. It is black, with the powder blackish gray and free from shining particles; it yielded to Maisch (*Proc. A. Ph. A.*, 1872) 1.016 per cent., and to L. Fahnestock 1.25 per cent., of cantharidin (*A. J. P.*, 1879). For further account of non-official blistering beetles, the reader is referred to the footnote, page 284.

Cantharis vesicatoria (L.), De Geer, Latr., *Gen. Crust. et Insect.*, ii. p. 220.—This beetle is from six to ten lines in length, by two or three in breadth, and of a shining, golden-green color. The head is large and heart-shaped, bearing two thread-like, black, jointed feelers; the thorax short and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. When alive, the Spanish flies have a strong, penetrating, fetid odor, compared to that of mice, by which swarms of them may be detected at a considerable dis-

membranous wings." Of *Mylabris* there have been used a *Vinegar*, (*Acetum Mylabridis*, Br. Add. two ounces to one pint); a *Warming Plaster* (*Emplastrum Calefaciens*, Br. Add.); a *Plaster* (*Emplastrum Mylabridis*, Br. Add.); and a *Blistering Liquid* (*Liquor Epispasticus Mylabridis*, Br. Add. ten ounces to one pint), and an *Ointment* (*Unguentum Mylabridis*, Br. Add. one ounce to ten ounces); evidently substituted for the corresponding preparations of cantharides.

¹ *Mylabris* of the Br. Add. is characterized as "usually an inch (twenty-five millimetres) or rather more long, and three-eighths of an inch (nine millimetres) broad; with two long elytra, each three times as long as broad, black with two broad wavy transverse orange-colored bands and a large orange-colored spot at the base of each; one pair of brown

tance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. They are most abundant in Spain, Italy, and Southern France, but are found also in all the temperate parts of Europe, and in Western Asia. According to the researches of Lichtenstein, the eggs are laid by the female in the latter part of June in small cylindrical holes made in the ground. A week later the larvæ hatch out. They are a millimeter long, with two long caudal threads, and of a brown color. After many efforts, Lichtenstein succeeded in getting them to feed on the honey contained in the stomach of bees. In a few days they changed into milk-white larvæ, and about a month after this buried themselves in the ground, to assume the chrysalis stage and to hatch out the following spring as perfected beetles. In the wild state the larvæ are said to crawl up flowers and attach themselves to bees or other hymenopterous insects; carried by the bee to the hive, the larvæ feed upon the young bees and the honey and bee-bread stored up for use. The beetles usually make their appearance in swarms upon the trees in May and June, when they are collected.

The time preferred for this purpose is in the morning, at sunrise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks, and their hands with gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the vapor of boiling vinegar, and, having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. In some places they are gathered by smoking the trees with burning brimstone. It has been proposed by Lutrand to destroy them by the vapor of chloroform. When perfectly dry, they are introduced into casks or boxes lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture. According to Neutwich, the young fly has no vesicating power (*P. J.*, Nov. and Dec., 1870, p. 355); but this is denied by H. Beauregard. (*Ibid.*, xv. 873.)

Cantharides come chiefly from Spain, Italy, Sicily, and other parts of the Mediterranean. Considerable quantities are also brought from St. Petersburg, derived originally, in all probability, from the southern provinces of Russia, where the insect is very abundant. The Russian flies are most esteemed. They may be distinguished by their greater size, and their color approaching to that of copper.

In the United States are several species of Cantharis, which have been employed as substitutes for *C. vesicatoria* and found equally efficient; but none of them are now recognized

by the U. S. Pharmacopœia, even *C. vittata*, which was at one time official, having been discarded.¹

¹*Blistering Beetles not official.* 1. *Cantharis vittata*. Latreille, *Gen. Crust. et Insect.*; Durand, *A. J. P.*, II. 274, fig. 4.—The "potato fly" is rather smaller than *C. vesicatoria*, which it resembles in shape. Its length is about six lines. The head is light red, with dark spots upon the top; the feelers are black; the elytra or wing-cases are black, with a yellow longitudinal stripe in the centre, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same color, are covered with a cinereous down. It inhabits chiefly the potato vine, and appears about the end of July or beginning of August, in some seasons very abundantly. It is found on the plant in the morning and evening, but during the heat of the day descends into the soil. The insects are collected by shaking them from the plant into hot water, and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States. This species of Cantharis was first described by Fabricius in the year 1781, and was introduced to the notice of the profession by Isaac Chapman of Bucks County, Pennsylvania, who found it equal if not superior to the Spanish fly as a vesicator. The testimony of Chapman has been corroborated by that of many other practitioners. It may be applied to the same purposes treated in the same manner, and given in the same dose as the foreign insect. W. R. Warner obtained 1.99 parts of cantharidin from 500 parts of this beetle, but by improved methods Fahnstock procured 1½ per cent. of the active principle. (*A. J. P.*, xxviii. 195; II. 298.) According to the researches of Jos. Leidy, the vesicating principle resides in the blood, the eggs, and a peculiar fatty matter of certain accessory glands of the generative apparatus (*A. J. M. S.*, Jan. 1869, p. 60); while H. Beauregard (*P. J.*, xv. 873) found that the blood, the seminal vesicles of the male, the eggs, and all parts of the generative organs of the female are active. This insect must not be confounded with the "potato bug" the *Colorado potato beetle* (*Doryphora decemlineata*) which has proved so destructive to potato plants, and which according to the researches of L. Dembinski (*A. J. P.*, 177, p. 550) contains no cantharidin.

2. *Cantharis cinerea*. Latreille, *Gen. Crust. et Insect.*; Durand, *A. J. P.*, II. 274, fig. 5.—The ash-colored cantharis closely resembles the preceding species in figure and size, but differs from it in color. The elytra and body are black without the yellow stripes that characterize *C. vittata*, and are entirely covered with a short and dense ash-colored down, which conceals the proper color of the insect. The feelers are black, and the first and second joints are very large in the male. This species also inhabits the potato plant, and is occasionally found on other plants, as the English bean and wild indigo. It is a native of the Northern and Middle States. Illiger in 1801 discovered its vesicating properties; but Gorham was first to call public attention particularly to the subject, and to the fact of its equality in all respects with the potato fly, in a communication addressed, in the year 1808, to the Medical Society of Massachusetts.

3. *Cantharis marginata*. Latreille, *Gen. Crust. et Insect.*; Durand, *A. J. P.*, II. 274, fig. 6.—This is somewhat larger than *C. vittata*, and of a different shape. The elytra are black, with the suture and abdomen ash-colored. The head, thorax, and margin are black, but nearly covered with an ash-colored down; and on the upper part of the abdomen, under the wings, are two longitudinal lines of a bright clay color. The insect is usually found, in the latter part of summer, upon different species of Clematis, and frequents especially the lower branches which trail along the ground. Woodhouse of Philadelphia, first ascertained its vesicating properties; but it had previously been described by Fabricius as a native of the Cape of Good Hope. Harris of Massachusetts, found it as efficient as any other species.

4. *Cantharis atrata*. Latreille, *Gen. Crust. et Insect.*; Durand, *A. J. P.*, II. 274, fig. 7.—The black cantharis is smaller than the indigenous species already described, but resembles *C. marginata* in figure. Its length is only four or five lines. It is distinguished by its size, and its uniform black color. It frequents more especially the different species of Aster and Soldado, though it is found also on *Brunella vulgaris*, *Ambrosia trifida*, and some other plants. Durand met with considerable numbers of this insect near Philadelphia, in the month of September; and they continued to appear till the middle of October. They are common in the Northern and

Properties.—"From 18 to 25 Mm. long, about 6 Mm. broad; flattish-cylindrical, with filiform antennæ; black in the upper part, with two long wing-sheaths, and ample membranous, transparent, brownish wings; elsewhere of a shining coppery-green color; odor strong and disagreeable; taste slight, afterwards acid. The powder is grayish-brown, with shining green particles, and contains few or no hairs; ash not more than 8 percent." *U. S.* Dried Spanish flies preserve the form and color, and, to a certain extent, the disagreeable odor, of the living insect. They have an acrid, burning, and urinous taste. Their powder is of a grayish-brown color, interspersed with shining green particles, which are the fragments of the feet, head, and wing-cases. If kept perfectly dry, in well-stoppered glass bottles, they retain their activity for a great length of time. A portion which had been preserved by Van Swieten for thirty years, in a glass vessel, was found still to possess vesicating properties. But exposed to a damp air they quickly undergo putrefaction, and this change takes place more speedily in the powder. Hence the insects should either be kept whole, and powdered as they are wanted

in the Middle States, but are not confined exclusively to this country, being found also in Barbary. Oswood and Harris of New England, satisfactorily ascertained their vesicating powers. They are probably identical with the insect noticed as vesicatory by Woodhouse, under the name of *Meloe niger*.

5. *Cantharis vulnerata*. Harrison Allen, *Medical Zoology*, 1st ed., p. 150.—Geo. H. Horn states that this is so abundant upon the Pacific coast that he has often seen bushels of the insects covering the ground. It has a black body, an orange-colored head, sometimes with a broad black stripe down the middle, and black wing-cases. Horn found it medicinally very active, as was also the less plentiful *C. melana*. Several other species have been discovered in the United States, but not yet practically employed. Among these are *C. aneas*, a native of Pennsylvania, discovered by Say; *C. politus* and *C. assechanus*, inhabiting the Southern States; *C. nuttalli*, a large and beautiful insect of Missouri, first noticed by Nuttall, and said to surpass the Spanish fly in magnitude and splendor; and *C. albida*, another large species, found by Say near the Rocky Mountains. Of these, *C. nuttalli* (*Lytta nuttalli*, Say, *Am. Entomol.*, 1. 9) bids fair, at some future period, to be an object of importance in the western section of the country. The head is of a deep greenish color, with a red spot in front; the thorax is of a golden green; the elytra red or golden purple and somewhat rugose on their outer surface, green and polished beneath; the feet black; the thighs blue or purplish. The exploring party under Colonel Long ascertained the vesicating powers of this insect. It was found on the plains of the Missouri, feeding on a scanty grass. In one spot it was so numerous as to be swept away by bushes, in order that a place might be cleared for encamping. There are also a number of beetles found in the United States which are plentiful enough to be capable of affording a commercial article, and which are so closely allied to the genus *Cantharis* as to render it probable that they possess blistering properties. For an account of the more important, see *Proc. A. Ph. A.*, 1876, p. 506.

Mylabris bifasciata and *M. lunata*, said to be common South African beetles used by the natives for producing vesication, have appeared in the London market. They yielded to J. Oldham Braithwaite from 1.09 to 1.02 per cent. of cantharidin. *Meloe proscarabæus* and *M. majalis* have been occasionally substituted for cantharides in Europe, and *M. trianthemus* is used in the upper provinces of Hindostan. J. O. Braithwaite found the *Mylabris bifasciata* of the Cape of Good Hope extremely rich in cantharidin, while its co-dweller, *M. lunata*, contained but little. (*P. J.*, xviii. 246.) *Hecynus sanguinea*, or "*Chinese cantharides*," of the London market, does not contain cantharidin. (*J. Moss*, *P. J.*, xvii. 845.) *Epicauta gortami* is said to be used in Japan as a cantharidal beetle. *Ph. Ztg.*, March, 1891.

for use, or, if kept in powder, should be well dried immediately after pulverization, and preserved in air tight vessels. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the hard exterior parts are not affected. An idea was at one time prevalent that the vesicating property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. Farines, an apothecary of Perpignan, has satisfactorily shown that, though the hard parts left by these mites possess some vesicating power, and the powder produced by them still more, yet the sound flies are much stronger than either. Camphor, which has been recommended as a preservative, does not prevent the destructive agency of the worm. It appears from the experiments of Nivet that, though camphor does not preserve the entire fly from the attacks of the larvæ of the *Anthrenus*, it actually destroys the mites of the *Cantharis* so often found in the powder, and may, therefore, be introduced with advantage, in small lumps, into bottles containing powdered cantharides. (*J. P. C.*, xix. 604.) Ammonium carbonate has also been recommended as a preservative. Pereira has found that a few drops of strong acetic acid, added to the flies, are very effectual. Among the best means of preserving them, whether whole or in powder, is the application of the process of Apert, which consists in exposing them for half an hour, confined in glass bottles, to the heat of boiling water, which destroys the eggs of the insect, without impairing the virtues of the flies. (*Ibid.*, xxii. 246.) Of course the access of water to the flies should be carefully avoided. Lutrاند recommends chloroform as the best preservative that he has tried. (*J. P. C.*, xviii. 214.) We have little doubt that exposure, in a confined vessel, to the vapor of phenol, would be a perfect protection against all forms of insect life. It is stated by Farines that when the flies are destroyed by the vapor of pyroligneous acid, instead of common vinegar, they acquire an odor which contributes to their preservation. Cantharides will bear a very considerable heat without losing the brilliant color of their elytra; nor is this color extracted by water, alcohol, ether, or the oils, so that the powder might be deprived of all its active principle and yet retain the exterior characters unaltered. The wing cases resist putrefaction for a long time, and the shining particles have been detected in the human stomach months after interment.

So early as 1778, Thouvenel attempted to analyze cantharides, and the attempt was repeated by Beaupoil in 1803; but no very interesting or valuable result was obtained until 1810, when Robiquet discovered in them a crystalline substance, which proved to be the

vesicating principle of the insect and received the name of *cantharidin*. The constituents, according to Robiquet, are—1, a green oil, insoluble in water, soluble in alcohol, and inert as a vesicatory; 2, a black matter, soluble in water, insoluble in alcohol, and inert; 3, a yellow viscid matter, soluble in water and alcohol, and without vesicating powers; 4, cantharidin; 5, a fatty matter, insoluble in alcohol; 6, calcium and magnesium phosphates, acetic acid, and, in the fresh insect, a small quantity of uric acid. Orfila afterwards discovered a volatile principle, upon which the fetid odor of the fly depends. It is separable by distillation with water. Dragendorff has found a volatile principle which acts on the system in the same manner as cantharidin. When powdered flies are moistened with water and distilled, the part which passes over, at or below 100° C. (212° F.), contains this principle. (*Chem. News*, May 31, 1867.) That the green coloring matter is chlorophyll seems to be shown by the experiments of Pocklington, who (*P. J.*, [3], iii. p. 681) found that when cantharides was treated with alcohol, ether, and carbon disulphide, the solutions yielded absorption spectra agreeing with that of chlorophyll. Cantharidin exists in commercial cantharides to the extent of from 0.6 to 0.9 per cent. (See also *Ph. Centralh.*, 1901, 674.) E. Dieterich prepares cantharidin by macerating 1000 parts of coarsely powdered cantharides in 1500 parts of acetic ether mixed with 20 parts of sulphuric acid; after adding 40 parts of barium carbonate to neutralize the excess of sulphuric acid, the mixture is exhausted with acetic ether in an extraction apparatus, the liquid is distilled, and the residue, consisting of cantharidin, resin, fat, etc., is set aside for eight days to allow the cantharidin to crystallize; 200 parts of petroleum benzin (sp. gr. 0.740) are then added, gently heated in order to dissolve the fatty matter, the liquid filtered, and the cantharidin washed with petroleum benzin and recrystallized from its solution in 90 per cent. alcohol. If perfectly pure cantharidin is needed, the cantharidin may be dissolved in acetic ether or chloroform and the solution passed through animal charcoal, filtered, and allowed to crystallize. (*J. P. C.*, 1893, 375.) For assay of cantharides for cantharidin see *P. J.*, 1903, 558 and 783.

Cantharidin is in the form of white crystalline scales, of a shining micaceous appearance, inodorous, tasteless, almost insoluble in water and in cold alcohol, but soluble in ether, chloroform, benzene, the oils, and in hot alcohol and acetic acid, which deposit it upon cooling. According to Procter it is insoluble in water. Cold alcohol dissolves it slightly, hot alcohol freely. It is more soluble in ether, which also dissolves it more freely hot than cold. Chloroform, cold or hot, is its best solvent; and acetone ranks next to it in this respect. Olive oil, at 250° F., dissolves one-twentieth of its weight, and oil of turpentine, boiling hot, one-seventieth; and both deposit the greater portion on

cooling. The olive oil solution after deposition vesicates, the terebinthinate does not. Strong acetic, sulphuric, and nitric acids dissolve it, with the aid of heat, and deposit it unchanged on cooling. It is also dissolved by solutions of potassium or sodium hydroxide, and to a small extent by a strong solution of ammonia. (*A. J. P.*, xxiv. 296.) Formic acid is said to be the best solvent. Somewhat different results in relation to the solubility of cantharidin have been obtained by M. E. Rowan. Careful experimentation with distilled water showed that, when agitated for eight days at ordinary temperatures with pure cantharidin, it was capable of dissolving 0.0266 per cent. of that principle; boiling water dissolves 0.297 per cent.; boiling alcohol (99° Tralles) 2.168 per cent. (*J. P. C.*, Mai, 1873, 409.) It fuses at 210° C. (410° F.), is volatilizable by heat without decomposition, and its vapor condenses in acicular crystals. As determined by the experiments of Wm. A. Guy, the subliming heat of isolated cantharidin is 100° C. (212° F.), or the temperature of boiling water. (*P. J.*, Feb. 1868, 373.)

According to Masing and Dragendorff, cantharidin, $C_{10}H_{12}O_4$, is capable of combining with water, and thus becomes cantharidic acid, $C_{10}H_{14}O_5$, and in this state forms definite compounds with bases, such as $K_2C_{10}H_{12}O_5$ and $Na_2C_{10}H_{12}O_5$, which are crystallizable. These may be obtained by heating cantharidin with an alkaline hydroxide solution. (*J. P. C.*, Janv. 1868, 79.) Cantharidin itself has been found to combine like an acid with the salifiable and earthy bases, forming soluble compounds with potassium, sodium, and lithium hydroxides, salts of very sparing solubility with baryta, strontia, and lime, and with magnesia a salt which, though feebly soluble in water (100 parts of water dissolving only 0.24 of the salt) (see *P. J.*, March 13, 1880), is much more largely dissolved in cold than in hot water, and in cold than in hot alcohol. Cantharidin is therefore recognized as the lactone or inner anhydride of cantharidic acid. The potassium salt crystallizes with 3 molecules of water, and is soluble in 25 parts of water. On the addition of strong acids to this solution, cantharidic acid is not precipitated, as might be expected, but the lactone cantharidin. This potassium salt has been recommended by Liebreich for use in subcutaneous injections in cases of *phthisis*, but is of very doubtful value. The most satisfactory test of cantharidin is its vesicating property. Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts act as effectually in exciting vesication as do the flies themselves, while the residue is in each case inert. Cantharidin consequently exists in the insect so combined with the yellow matter as to be rendered soluble in water and cold alcohol. If, as stated by E. Dieterich (1883), formic acid is present in the

Spanish fly, it is probable that the solution of the cantharidin is due to its presence. He also showed that cantharidin was not volatilized with the vapor of benzin, a fact which may prove useful in preparing blistering plasters coated with a benzin solution of cantharidin. (*Ph. Centralh.*, 1901, 464.) H. G. Greenish calls attention to the fact that much loss of cantharidin takes place in making the various pharmaceutical preparations, through insufficient exhaustion by the use of the ordinary solvents. He obtained 0.822 per cent. of cantharidin from exhausted residues. Homolka records (*Ber. d. Chem. Ges.*, xix. 1082), the results of an investigation of the chemical decompositions of cantharidin.

Adulterations.—These are not common. Occasionally other insects, or even beads, are added, purposely, or through carelessness. These may be readily distinguished by their appearance. Flies exhausted of their cantharidin are sometimes substituted for the genuine drug. They are worthless, and are to be distinguished by their lack of substance and their yielding a nearly colorless ethereal tincture. Pereira states that powdered flies are sometimes adulterated with euphorbium. According to the researches of Fahnestock (*A. J. P.*, 1879, p. 298), age destroys the activity of the drug without of necessity impairing its physical appearance.

The percentage of cantharidin found in cantharides furnishes the best test of their virtues. Wm. Procter succeeded, by means of chloroform, in isolating cantharidin with great facility. He treated the flies with chloroform by percolation, displacing the last portion by means of alcohol, and allowing the resulting solution to evaporate spontaneously. Cantharidin is thus obtained in crystals mixed with the green oil, the greater portion of which may be removed by bibulous paper. The residuary crystals are dissolved in a mixture of ether and alcohol, which, by the spontaneous evaporation of the ether, yields the cantharidin nearly pure. Mortreux, having ascertained that the cantharidin is insoluble in carbon disulphide, proposed to use this fluid for removing the fatty matter associated with the cantharidin crystals obtained by the use of chloroform. He employed the same liquid in estimating the proportion of cantharidin, which he found to be about 20 centigrammes for 40 grammes of the flies, or half of one per cent. (*J. P. C.*, 3e sér., xlvii. 33, 1864.) Wittstein obtains it by digesting coarsely powdered flies repeatedly with water, straining through linen and expressing, allowing the liquid to settle for a day, separating the supernatant oil, adding a little wood charcoal, evaporating to dryness, treating the residue with ether so long as the solution affords a laminated substance on evaporation, evaporating the ethereal solution, treating the residue with cold alcohol of 80 per cent. for one day with frequent shaking, and finally drying the scales. (See *A. J. P.*, xxviii.) Williams has obtained it by means of benzene. (*Ibid.*,

xxvi.) For a method of assaying cantharides and its official preparations by H. G. Greenish and Harold Wilson, see *P. J.*, 1898, 255, or *Am. Drug.*, 1898, 224.

Uses.—Internally administered, cantharides is a powerful irritant, with a peculiar direction to the urinary and genital organs. Genito-urinary irritation is ordinarily the first symptom produced by small doses of cantharides, and, if the dose has been large enough, it may amount to violent strangury, attended with excruciating pain, and the discharge of bloody urine. Toxic doses of Spanish fly produce obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, excessive salivation with a fetid breath, hurried respiration, a hard and frequent pulse, burning thirst, exceeding difficulty of deglutition, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Orfila has known twenty-four grains of the powder to prove fatal. Dissection reveals inflammation and ulceration of the mucous coat of the whole intestinal canal. According to Poumet, if the intestines be inflated, dried, cut into pieces, and examined in the sun between two pieces of glass, they will exhibit small shining yellow or green points, strongly contrasting with the matter around them. (*J. P. C.*, 3e sér., iii. 167.)¹

The poisonous effects are to be counteracted by the use of emetics, cathartics, and opiates by the stomach and rectum. From the experiments of Schroff it seems that oils somewhat accelerate the poisonous action, probably by dissolving the cantharidin. (See *A. J. P.*, xxviii. 365.) By experiments upon dogs, Thouery, a French apothecary, has satisfied himself that animal charcoal possesses a real antidotal power. (*J. P. C.*, 1858, p. 65.) Cantharides have been long and beneficially used in medicine. Either these or other vesicating insects appear to have been given by Hippocrates in *dropsy* and *amenorrhœa*, in the latter of which complaints, when properly prescribed, they are a highly valuable remedy. They are also useful in obstinate *gleet*, *leucorrhœa*, and *seminal weakness*, and in *paralytic incontinence of urine*. They are used also in certain cutaneous eruptions, especially those of a scaly character, and in chronic *eczema*. Their unpleasant effects upon the urinary passages are best obviated by the free use of diluent drinks, or when severe, by opiate enemata. The dose of cantharides is one or two grains (0.065 to 0.13 Gm.) of the powder, which may be given twice a day, in the form of pill. The tincture, however, is more frequently employed.

Externally applied, cantharides excites inflammation in the skin, which terminates in a copious secretion of serum under the cuticle.

¹ Cantharidin may be detected in the body after death from poisoning. Dragendorff states that he has succeeded in finding it in the dead body of a cat three months after it had been taken, and is convinced that it might be discovered in the human corpse six months after burial. (*J. P. C.*, 1873, p. 443.)

It may be employed either as a rubefacient, or to blister. In the former capacity it is seldom used, but as an epispastic it is preferred to all other substances. When blisters are allowed to stay on only long enough to irritate the skin, but not to blister, they are known as *flying blisters*. Used in this way, they are sometimes of service in *neuralgias*, applied directly over the seat of pain. Their chief value is, however, found in cases of severe internal irritation. It is of great importance that the practitioner should clearly comprehend the distinct uses of the rubefacient and the blister. The rubefacient is to be employed as a revulsive when the internal irritation is severe but is not connected with pronounced organic change. The immediate impression of a rubefacient, acting as it does upon a much larger surface than does the blister, is greater than that of the blister, but the permanent revulsive action is much less. The blister is, therefore, to be used when the internal disease is connected with inflammatory structural change. Thus, in a case of *gastrodynia*, a rubefacient is of much more service than a blister, while the blister is decidedly more effective in *peritonitis*. In a general wide-spread congestion of the lung the rubefacient is to be preferred to the blister, but in *pneumonia* the blister to the rubefacient. As, however, congestion of neighboring parts usually accompanies a localized inflammation, a rubefacient is sometimes to be employed as a temporary substitute for or adjuvant to a blister. The amount of serous discharge produced by blisters appears to be sometimes of service in almost directly evacuating local serous exudations. Thus, not rarely repeated blistering affords the best treatment of a *serous pleurisy*. Possibly, however, even in these cases, the blister acts purely as a counter-irritant, as it certainly does in *chronic rheumatism* and other diseases of the joints. In all *chronic joint inflammations* the best results may often be obtained by a reblistering, extending, if necessary, over weeks and months. In some cases of *skin disease* blisters are capable of substituting their own action for the original morbid disease, and they are still occasionally used for this purpose in *tinea capitis*, obstinate *herpes*, and other affections. The length of time that a blister should be applied varies with the individual and with the position of the disease. In some constitutions they produce a poisonous impression, attended with frequent pulse, dryness of the mouth, subsultus tendinum, and even convulsion. Such symptoms are probably the results of an intense peripheral nervous irritation acting upon very susceptible centres. Such is not, however, the case with the strangury which may follow absorption of the cantharidin, and which is always the result of the direct action of the cantharidin upon the genito-urinary tract. In order to avoid such genito-urinary irritation, and also as much as possible the pain at the seat of application, the blister should be left on only until it distinctly

reddens the skin, when a flaxseed poultice may be applied, and in the course of two or three hours the blister is formed. The time necessary for such reddening of the skin is usually from four to six hours, if the cantharidin be active. (See *Ceratum Cantharidis*.)

Liebreich strongly recommends hypodermic injections of cantharidin in the treatment of *phthisis*, but general clinical experience has not confirmed the value of the remedy. *Liebreich's cantharidal solution* was made by heating 20 Cc. of water with 0.2 Gm. of cantharidin and 0.4 Gm. of potassium hydroxide until solution was obtained, then adding enough water to make 1000 Cc. The dose of the cantharide was 0.0001 Gm. increased to 0.0002 Gm., or even beyond.

Dose (official), of cantharides, one-half grain (0.032 Gm.), but it is rarely used internally.

CAPSICUM. U. S. (Br.)

CAPSICUM [Cayenne Pepper]

(căp'si-cūm)

"The dried, ripe fruit of *Capsicum fastigiatum* Blume (Fam. *Solanaceæ*), deprived of its calyx." U. S. "The dried, ripe fruit of *Capsicum minimum*, Roxb." Br.

Capsici Fructus, Br.; Piper Hispanicum; Capsicum Fruit, African or Pod Pepper, Red pepper, Chillies, Bird Pepper, Spur Pepper, Paprika; Fructus Capsici, P. G.; Spanischer Pfeffer, Schlotenpfeffer, G.; Piment de Cayenne, Piment des jardins, Poivre d'Espagne, Poivre de Guinée, Poivre d'Inde, Poivre de Cayenne, Piment rouge, Capcique, Fr.; Peperone, It.; Pimiento, Chile, Ajil, Sp.

Owing probably to its wide-spread cultivation, the genus *Capsicum* contains a large number of plant forms whose specific relations afford a very difficult problem to the systematic botanist. The probability is that the entire genus was originally confined to the American tropics, although it has been cultivated since the time of Columbus in the temperate and tropical zones of almost the whole world. Its first appearance in literature seems to be in an epistle by Peter Martyn, dated September, 1493, speaking of its having been brought by Columbus. Neither in ancient Sanscrit, Chinese, Greek, Latin, or Hebrew is there a name for it. In 1887 Asa Gray expressed his belief that there are only two species in the genus, although in the last previous revision of the genus, in 1852, Dunal had recorded fifty species. After a very thorough and careful study of the subject, including the cultivation of every procurable variety and species for four years in the Missouri Botanical Garden, H. C. Irish has reached the conclusion that the dictum of Gray

was correct, and that there are really only two species of the genus, one of which is herbaceous and annual or biennial, the other shrubby and perennial, a conclusion which seems to be accepted.

The first of these species is the one most extensively cultivated in Europe and in this country; it is the *C. annum*, L. The second is in its varieties very largely grown in the tropical and subtropical latitudes, its fruit not ripening at all or only to a slight degree in the temperate zone. It is the species which was described under the name of *C. frutescens*, by Linnæus, in 1737. By Irish it is divided into two varieties,—*C. frutescens* proper, which is characterized by its fruit being oblong, acuminate, and usually embraced by the calyx, and *C. frutescens baccatum*, which is characterized by its ovate or subround fruit, usually seated on the calyx. This variety is the *C. baccatum* of Linnæus, 1767. In the first of these varieties are comprised the *C. fastigiatum* of Blume and the *C. minimum* of Miller and of Roxburgh, which yield most of the Cayenne pepper produced in the tropics, although, especially in the West Indies and South America, *C. baccatum* is largely cultivated. It is even doubtful whether *C. annum* should be considered as a distinct species from *C. frutescens*, as in tropical climates varieties have been produced which are perennial and somewhat woody.

The British Pharmacopœia seems to be in error in ascribing the original description of the *Capsicum minimum* to Roxburgh, since his *Flora Indica* did not appear until 1832, whereas the species was described by Miller, in the *Garden Dictionary*, in 1771.

Capsicum annum, Willd., *Sp. Plant.* i. 1052; B. & T. 189.—The stem of the annual capsicum is thick, roundish, smooth, and branching; rises two or three feet in height, and supports ovate, pointed, smooth, entire leaves, which are placed without regular order on long footstalks. The flowers are solitary, white, and stand on long peduncles at the axils of the leaves. The calyx is persistent, tubular, and five-cleft; the corolla, monopetalous and wheel-shaped, with the limb divided into five spreading, pointed, and plaited segments; the filaments, short, tapering, and furnished with oblong anthers; the germen, ovate, supporting a slender style which is longer than the filaments and terminates in a blunt stigma. The fruit is a pendulous, pod-like berry, of varying shape and size, light, smooth, and shining, of a bright scarlet, orange, or sometimes yellow color, with two or three cells, containing a dry, loose pulp, and numerous flat, kidney-shaped, whitish seeds.

The following are the characteristics of the two varieties of the shrubby or perennial capsicum, as given by Irish:

C. frutescens, Linn.—“Plants shrubby, perennial, two and a half to six feet high. Branches angular, often channelled, puberulent or pubescent, especially on the younger portions; usually

greatly enlarged at the nodes, green or sometimes purplish striate, slightly purple at the nodes. Leaves broadly ovate, acuminate, three to six inches long, two to three and one-half inches wide, usually puffed or wrinkled, more or less pubescent, especially around the veins. Petioles medium, usually subciliate; peduncles slender, one to two inches long, often in pairs, usually longer than the fruit. Calyx usually cup-shaped, embracing base of the fruit; teeth short, corolla white or greenish white, spreading three-eighths to three-quarters inch, often with ocherous markings in the throat. Fruit red, ovate, obtuse or oblong acuminate, three-quarters to one and one-quarter inches long, one-quarter to three-quarters inch diameter.”

C. frutescens baccatum, Linn.—“Plants one to three feet high, under cultivation often six feet. Branches numerous, slender, fastigate flexuose, usually quite densely purple, striate, scabrous, pubescent. Leaves ovate, acuminate, rather abruptly narrowing into the petioles, solitary or in twos, more or less pubescent along the veins and sometimes on the surface. Petioles short, usually hairy, broadened at base. Peduncles solitary or in twos, extreme axillary vertical (giving a peculiar character to the fruit), slender; one to one and one-quarter inches long, smooth, or in young specimens subhairy. Calyx short, cyathiform, subhairy, subciliate. Corolla small, spreading about one-half inch, greenish white. Fruit ovate or subround, about one-quarter inch diameter. Unripe fruit sometimes changing from green to blackish spotted, finally ripening into a red or yellow.”

Capsicum annum is largely cultivated both in the United States and in Europe, flowering in the early or middle summer, and ripening its fruit in the early autumn. There are numerous varieties of it differing in the shape of their fruit. That which is chiefly cultivated in the United States for market, to be used in the green state in pickling, or cooked for the table, is a large irregularly ovate or conical berry, depressed or horned at the extremity, and when ripe varying in color from yellowish to scarlet. A variety with a long, conical, pointed and recurved fruit, which is usually not thicker than the finger, is said to be especially used in the making of red pepper. In another variety the berries are not more than an inch in diameter, spherical and slightly compressed.

When ground into powder the fruit of the *Capsicum annum* constitutes *paprika*, or as it is sometimes called, *sweet pepper*; it is very little used by itself but is largely employed for the mixing with the powder of chillies or true cayenne pepper; it has scarcely more than one-sixth the pungency of real cayenne pepper, so that the addition of it to powdered chillies may almost be considered an adulteration.

Paprika is to be distinguished, when pure, by its light yellowish color, and by its comparatively feeble taste. The cayenne pepper of the

grocery stores is very largely a mixture of paprika and true pepper. The microscopic characteristics in the fruits of the two species are not sufficiently pronounced to be of avail in detecting the presence of the feebler substance in the powdered pepper, although, according to T. Edward Wallis, the outer portions of the pericarp of *Capsicum annuum* are cuticularized or suberized, while in *Capsicum fastigiatum* all the cells are composed purely of cellulose. True cayenne pepper, *Chillies* or *Bird pepper*, is produced in almost all tropical and sub-tropical countries, but is said to come in very large proportion from Zanzibar. The pod is at once distinguished by the peculiar thinness and tendency to wrinkle of its outer coating.

The varieties of cayenne pepper are numerous as they occur in the American market—the pods of the *East African pepper* are half an inch in length, flattened, almost cylindrical, although showing distinctly the conical form; the pods of the *Madagascar peppers* reach the length of two and a half to three inches and a breadth of three-fourths of an inch; those of the *Bombay or cherry pepper* are very dark in color, one and a half to two inches in length, and half an inch or more in breadth at the base. They are strictly conical and less likely to be flat than those of the other varieties. *Zanzibar pepper* is smaller than the *East African pepper* but otherwise similar to it. *Japanese capsicum*, whose botanical source is not positively known, occurs in the market in two forms, one in which the pods are large, reaching the length of two and a half inches; the other in which the small pods are not over an inch in length. The larger pods are scarcely to be distinguished from *Madras Chillies*; the smaller resemble, but are nearly twice the size of, the *East African pepper*. The color of the pods varies from light yellowish brown to deep red.¹

The U. S. Pharm. describes the fruit of *C. fastigiatum* as follows: "Oblong-conical, from 10 to 20 Mm. long, with a red, shining, membranous and translucent pericarp; two-celled, and containing 10 to 20 flat, reniform, yellowish seeds attached to a thick, central placenta; odor distinct; taste intensely pungent. Few or no starch grains or sclerenchymatous fibres

should be present in the powder." U. S. The Br. Pharm. gives the characteristics of the fruit of *C. minimum* as "Dull orange-red, oblong-conical, obtuse, two-celled fruits, from about one-half to three-fourths of an inch (twelve to twenty millimetres) in length and a quarter of an inch (six millimetres) in diameter; sometimes attached to a five-toothed inferior calyx, and a long, straight, slender peduncle. The pericarp is somewhat shrivelled, glabrous, translucent, and leathery, and contains from ten to twenty small flat seeds, either loose or attached to a thin reddish dissepiment." Br.

The difficulty of distinguishing the source of powdered capsicum is increased by the fact that the red color fades upon exposure to light, and that the powdered African pepper, though very powerful, is a light brownish-yellow. The value of any specimen may be, however, fairly estimated by the intensity of its odor, which is peculiar, somewhat aromatic, and extremely irritant, and by its acrid, burning taste. The pungency appears to depend on a peculiar principle, which was obtained, though not in a perfectly isolated state, by Braconnot, and named *capsicin*. It is obtained as a thick yellowish-red liquid, but slightly soluble in water. When gently heated it becomes very fluid, and at a higher temperature is dissipated in fumes which are extremely irritating if inhaled. Capsicin is a mixed substance, consisting of resinous and fatty matters. In 1876, Thresh isolated a well defined active principle, *capsaicin*, from the extract which he obtained by exhausting Cayenne pepper with petroleum. From the red liquor dilute caustic alkali removes capsaicin, which is to be precipitated in minute crystals by passing carbon dioxide through the alkaline solution. The crystals may be purified by recrystallizing them from either alcohol, ether, petroleum benzin, glacial acetic acid, or hot carbon disulphide; in petroleum, capsaicin is but sparingly soluble, yet it is dissolved abundantly on the addition of fatty oil. The crystals of capsaicin are colorless, and answer to the formula $C_{26}H_{44}O_2$; they melt at 59° C. (138.2° F.), and begin to volatilize at 115° C. (239° F.), but decomposition can be avoided only with great care. The vapors

¹ T. Edward Wallis believes that the different cayenne peppers can be distinguished from one another when powdered by the character of their epidermis and the tissue immediately below it, and gives the following tabulated summary of the differences. (P. J., July, 1902.)

	<i>C. minimum.</i>	<i>C. annuum.</i>	<i>Japanese Chillies.</i>
<i>Epidermis.</i>	Thick and straight-walled rectangular cells with few pits; often arranged in groups of five to seven in a row and with a uniformly striated cuticle. Size of cells, 25 mkm. to 60 mkm. in either direction.	Irregular polygonal cells with evenly thickened walls, traversed by numerous well-marked, simple pits. The cuticle shows striated ridges. Size of cells, 60 mkm. to 100 mkm. long, and 25 mkm. to 50 mkm. wide.	Cells with strongly thickened walls and a radiated lumen. The pits only rarely penetrate the whole thickness of the wall. No visible striation. Size of cells, 30 mkm. to 80 mkm. long, and 15 mkm. to 45 mkm. wide.
<i>Hypoderma.</i>	Delicate thin-walled cellulose cells.	Several layers of cuticularized collenchymatous cells, having a rounded outline and very few pits.	A single layer of regular polygonal cells with cuticularized, fairly thick walls, traversed with numerous pits, which give them a beaded appearance.

of capsaicin are of the most dreadful acidity, and even the ordinary manipulation of that substance requires much precaution. Felletar (*J. P. C.*, Avril, 1870, p. 347) first obtained from capsicum fruits a volatile alkaloid, which resembles coniine in odor, but is distinguished by the different shape of its hydrochloride crystals. H. Pabst (1892) made a thorough investigation of the fruit of *C. annuum*. He does not think that an alkaloid exists originally in the fruit, but believes that the alkaloidal reactions are due to a decomposition product. He finds, besides capsaicin, a red coloring matter, and oleic, palmitic, and stearic acids. The red coloring matter, by saponification, was shown to be a cholesterol ester of the fatty acids. (*A. J. P.*, 1892, 370.) Moerbitz (1898) isolated a pungent principle having a bitter taste, which he states is neither capsaicin nor capsicol, and names *capsicutin*. He gives it the formula $C_{25}H_{44}N_2O_4$, and states that it is neither an alkaloid nor glucoside; it does not have acid properties. Red lead oxide is sometimes added to the powdered capsicum sold in Europe; it may be detected by digestion in diluted nitric acid, and precipitating the lead by sodium sulphate. Capsicum is said to be sometimes adulterated with colored sawdust, which may be recognized by the microscope. It is often adulterated with inert vegetable substances. The British Pharmacopœia requires that capsicum should yield on incineration not more than 6 per cent. of ash; this test would detect the presence of most adulterants. It is occasionally attacked by insects.

Uses.—Capsicum is a very powerful local stimulant, producing, when swallowed, a sense of heat in the stomach, and a general glow over the body without any narcotic effect. It is much employed as a condiment, especially in hot climates, and is useful in cases of atony of the stomach or intestines. It is strongly contraindicated by the existence of gastric catarrh of the ordinary type, but in the chronically inflamed stomachs of persons of intemperate habits it frequently appears to do good, probably by lessening the size of the dilated blood vessels and thereby relieving chronic congestion. It is often added with advantage to tonic prescriptions in cases of *neurasthenia*.

Applied externally, Cayenne pepper is a powerful rubefacient, which has the advantage of acting speedily without danger of producing vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a lotion, mixed with heated spirit. The powder or tincture brought into contact with a relaxed *wula* often acts very beneficially. The tincture has also been used advantageously in *chilblain*. The fluidextract and the oleoresin (*Oleoresina Capsici*, *U. S.*) are powerfully rubefacient. A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or by adding half a fluid-ounce of the tincture to eight fluidounces of rose water.

Dose, of the powder, from one to ten grains (0.065 to 0.65 Gm.), which is most conveniently given in the form of pill. Of an infusion prepared by adding two drachms to half a pint of boiling water, the dose is half a fluid-ounce (15 Ce.).

CARBO.

CARBON

(câr-bō)

C = 11.91

Carbone, *Fr.*; Kohlenstoff, *G.*; Carbone, *It.*; Carbon, *Sp.*

Carbon is an element of great importance, and very extensively diffused in nature. It exists in large quantity in the mineral kingdom, and is the most abundant constituent of animal and vegetable matter. In the crystallized state it constitutes the diamond; and, more or less pure, it forms the substances called graphite (or black lead and plumbago), anthracite and bituminous coal, coke, animal charcoal, and vegetable charcoal. Combined with oxygen it forms *carbon dioxide*, or *carbonic acid gas*, which is a constituent of the atmosphere, and present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base it forms the carbonates, among others *calcium carbonate*, which is one of the most abundant minerals. There are three allotropic conditions of carbon, represented respectively by the diamond, graphite, and charcoal.

The diamond has been found in quantity in India, in Brazil, and in South Africa, but at the present time is obtained almost exclusively from the last named locality. Several diamonds have been found in the gold regions of Georgia and North Carolina. This gem is perfectly transparent, and the hardest and most brilliant substance in nature. Its sp. gr. is about 3.5. It is fixed and unalterable in the fire, provided air be excluded, but is combustible in air or oxygen, the product being the same as when charcoal is burned, namely, carbon dioxide. It has been made artificially at the temperature of the electric arc (2500° to 3000° C.) by Moissan.

Next to diamond, graphite or plumbago is the purest natural form of carbon. Graphite is the substance of which black-lead crucibles and pencils are made. It is found in greatest purity in the mine of Borrowdale, in England, and in Ceylon, from which latter place most of the graphite of commerce is now obtained, but it also occurs very pure in this country, and in extensive deposits at Ticonderoga, N. Y., at Stourbridge, Mass., and in Canada. In physical characters it is utterly different

from the diamond; it crystallizes in hexagonal plates, is very soft and unctuous, of 2 to 2.5 sp. gr., and generally contains a little ash. In connection with the production of silicon carbide (carborundum) in the electric furnace, Acheson has produced a very pure artificial graphite by simply increasing the heat until the silicon was volatilized. This artificial graphite has a specific gravity of 2.5, is soft and of high metallic lustre. It is extensively used for electrodes in the electrolysis of brine and similar operations, and for graphite paint. *Anthracite*, the purest variety of natural coal, occurs in different parts of the world, but particularly in the State of Pennsylvania. It contains from 90 to 95 per cent. of carbon, and several per cent. of ash. *Bituminous coal* is another variety, containing, besides the fixed or free carbon, some 10 to 15 per cent. of volatile hydrocarbons or gas-making material. When this is driven off by the process of charring, as in the manufacture of coal-gas, a kind of mineral charcoal, called *coke*, is obtained, very useful in the arts as a fuel. When peat is charred, it is converted into *peat charcoal*, which forms a cheap disinfectant and deodorizer, applicable to the purification of hospitals, dissecting-rooms, factories, privies, etc.

Carbon may be obtained in a state approaching to purity by several processes. One method is to expose lamp-black to a full red heat in a close vessel. It may also be obtained, in a very pure state, by passing the vapor of volatile oils through an ignited porcelain tube, whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. The purest lamp-black is now made from natural gas in Western Pennsylvania and in Ohio. This lamp-black is miscible with water, does not color ether, and is free from oily matter.

Properties.—Carbon, in its uncrystallized state, is an insoluble, infusible solid, generally of a black color, and without taste or odor. It burns when sufficiently heated, uniting with the oxygen of the air, and generating carbon dioxide. Its sp. gr. in the solid state, apart from its pores when in mass, is 3.5; but with the air of the pores included, it is only 0.44. It is an almost unalterable and indestructible substance, and has great power in resisting and correcting putrefaction in other bodies. When properly prepared, it possesses the property of absorbing the coloring and odorous principles of most liquids. (See *Carbo Animalis*.) Its other physical properties differ according to its source and peculiar state of aggregation. As a chemical element it enjoys a very extensive range of combination. It forms two compounds with oxygen, *carbon dioxide* (carbonic acid gas) and *carbon monoxide* (carbonous oxide). With hydrogen it forms a number of compounds, called *hydrocarbons*, of which the most interesting are light carburetted hydrogen or marsh-gas, olefiant gas, acetylene, the hydrocarbons constituting petroleum, and the various essential oils. With nitrogen, carbon constitutes

cyanogen, the compound radical of hydrocyanic or prussic acid, and when united in minute proportion with iron as carbide it is present in cast iron and steel.

CARBO ANIMALIS. U. S.

ANIMAL CHARCOAL

(cār'bō ān-j-mā'lis)

“Charcoal prepared from bone.” U. S.

Spodium, Ebur Ustum; Bone Black, Ivory Black; Charbon Animal Ordinaire, *Fr.* *Cod.*; Noir Animal Pulvérisé, Noir d'os, *Fr.*; Thierische Kohle, Knochenkohle, Beinschwarz, Thierkohle, *G.*; Nero di ossa, Carbone animale, *It.*; Carbon animal, Carbon de hueso, *Sp.*

Animal charcoal was not retained in the British Pharmacopœia (1898).

The animal charcoal employed in pharmacy and the arts is usually obtained from bones, by subjecting them to a red heat in close vessels. The residue of the ignition is a black matter, which when reduced to powder forms *bone black*, sometimes incorrectly called *ivory black*. Ivory by carbonization will furnish a black which, on account of its fineness and intensely black color, is more esteemed than the ordinarily *bone black*, but is much more expensive.

In manufacturing bone black, the bones, first treated with steam to separate the fat, are subjected to destructive distillation in iron cylinders connected with vessels which receive the ammoniacal liquor, called *bone spirit*, together with a dark tarry liquid (*bone oil*), this being a secondary product of the operation. When the distillate ceases to come over, the residue is charred bone, or bone black. Bone consists of animal matter with calcium phosphate and carbonate. In consequence of the decomposition of the animal matter involved in this destructive distillation, the nitrogen and hydrogen, united as ammonia, and a part of the charcoal, in the form of carbon dioxide, distil over, while the remainder of the charcoal is left in the cylinder, intermingled with the calcareous salts. Diess of Paris, proposes carbon disulphide as a solvent for the fat of bones, as it furnishes a larger and better product of fat, and renders the bones fitter for producing a good bone black. This form of animal charcoal necessarily contains calcium phosphate and carbonate.

Properties.—“Dull black, granular fragments, or a dull black powder, odorless, nearly tasteless, and insoluble in water or alcohol. When ignited, it leaves a grayish or yellowish-white ash, amounting to about 85 per cent. of the original weight of the portion taken, which should have been previously dried at 120° to 125° C. (248° to 257° F.) to a constant weight. The ash should be soluble in hydrochloric acid with the aid of heat, leaving not more than a trifling residue. If 1 Gm. of Animal Charcoal be boiled for several minutes with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of

water the filtrate should be colorless or nearly so (evidence of *complete carbonization*).” *U. S.* It is more dense and less combustible than vegetable charcoal; from which, moreover, it may be distinguished by burning a small portion of it on a red hot iron, when it will leave a residue imperfectly acted on by sulphuric acid, whereas the ashes from vegetable charcoal readily dissolve in this acid, forming a bitterish solution.

Animal charcoal by no means invariably possesses the decolorizing property, as this depends upon its peculiar state of aggregation. If pure animal matter (soft tissues) is carbonized, it usually enters into fusion, and, from the gaseous matter which is extricated, becomes porous and cellular. The charcoal formed has generally a metallic lustre, and a color resembling that of black lead. It has, however, little or no decolorizing power, even though finely pulverized.

The decolorizing power of vegetable charcoal was first noticed by Lowitz of St. Petersburg; and that of animal charcoal by Figuier of Montpellier, in 1811. In 1822 the subject was ably investigated by Bussy, Payen, and Desfosses. The power is generally communicated to charcoal by igniting it in close vessels, but not always. The kind of charcoal, for example, obtained from substances which undergo fusion during carbonization scarcely possesses the property, even though it may be afterwards finely pulverized. The property in question is possessed to a certain extent by wood charcoal, but is developed in it in a much greater degree by burning it with some chemical substance, which may have the effect of reducing it to an extreme degree of fineness. The most powerful of all the charcoals for discharging colors are those obtained from certain animal matters, such as dried blood, hair, etc., by first carbonizing them in connection with potassium carbonate, and then washing the product with water. Charcoal thus prepared seems to be reduced to a state of extremely minute division, and is, therefore, very porous. The next most powerful decolorizing charcoal is *bone black*, in which the separation of the carbonaceous particles is effected by the calcium phosphate present in the bone. Vegetable substances also may be made to yield a good charcoal for destroying color, provided, before carbonization,

they be well comminuted, and mixed with pumice stone, chalk, flint, or other similar substance in a pulverized state.

In the manufacture of yellow prussiate of potash there is obtained a fine black sediment, which has a powerful decolorizing action; this is sometimes attributed to the organic nitrogenous character of the material from which it is made.

The table below, abridged from one drawn up by Bussy, denotes the relative decolorizing power of different charcoals.

In order to determine the commercial value of animal charcoal, Corenwinder has proposed to ascertain its power of absorbing lime from a solution of calcium saccharate of determinate strength. The value is in proportion to the absorbing power of the charcoal. A given weight of the charcoal to be tested is left in contact, for an hour, with a given volume of the solution of the saccharate, taken in excess. The liquid is then filtered, and a small measure of it saturated with diluted sulphuric acid of known strength. The less the acid necessary for this purpose, the greater the amount of lime absorbed, and the better the animal charcoal. (*Chem. Gaz.*, 1854; *Scientific American*, April 22, 1876; *A. Pharm.*, 1887; *Proc. A. Ph. A.*, 1887.) See also Laval's investigations, *P. J.*, 1900, 214. Dupuy found that the addition of a few grains of animal charcoal to a few cubic centimeters of cold fresh tincture of guaiacum immediately causes the development of a blue color, while wood charcoal does not give this reaction (*P. J.*, 1897, 190).

Spent animal charcoal, which has been used by the sugar refiners, may have its decolorizing power restored by calcination, which destroys the organic matters that have become fixed in it, and it is stated that it may be submitted to this process twenty times before becoming unfit for use, although this depends upon the amount of calcium salts it takes up from the raw sugars, beet sugars using up the black faster than sugars from the cane. According to Pelouze, the same object may be accomplished by subjecting it to a weak solution of potassium or sodium carbonate. In removing the coloring matter, the alkaline solution becomes yellow. After its action the animal charcoal must be carefully washed, first with boiling water, and afterwards with acidulated water. A process devised by

KINDS OF CHARCOAL.

Blood ignited with potassium carbonate	20	50

Leplay and Cuisinier is probably more effectual. The charcoal, without being removed from the cylinders, is thoroughly washed, treated by steam to remove viscous substances, and then percolated successively, 1, by a weak alkaline solution, which removes salts and some coloring matter; 2, by weak hydrochloric acid, which, in removing a certain amount of salts of lime, liberates coloring matter; 3, again with a weak alkaline solution, to carry off the remaining coloring matter; and 4, lastly by a solution of calcium biphosphate, by which the decolorizing power of the charcoal is restored.

Animal charcoal is capable of taking the bitter principles from infusions and tinctures, and iodine from liquids which contain it in solution. Its power, however, of acting on solutions and chemical compounds is stated by Warington and Weppen to be more decided in its purified condition. (See *Carbo Animalis Purificatus*; see also *Ephem.*, 1885, p. 721.) On the other hand, Carswell (*P. J.*, 1893, 615) believes that the purification of animal charcoal is based on erroneous conclusions as charcoal possesses no inherent powers of decolorization but the latter depends partly on the aggregation of cellular spaces and chiefly on the mineral constituents.

Bone black consists of about 90 per cent. of calcium phosphate and carbonate, and 10 per cent. of charcoal.

Uses.—Animal charcoal is used in pharmacy for decolorizing vegetable principles, such as gallic acid, quinine, morphine, veratrine, etc., and in the arts, principally for clarifying syrups in sugar refining, for depriving spirits distilled from grain of the penetrating impurity, called *fusel oil*, which imparts to them an unpleasant odor and taste, as first distilled, and for the filtration of petroleum residues in the manufacture of petrolatum and petroleum jellies. (See *Petrolatum*.) The manner in which it is used as a decolorizer is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites with the coloring matter, and the solution by filtration is obtained white and transparent. Its use, however, in decolorizing the alkaloids and other vegetable principles, no doubt causes a loss by absorption, since it has been shown by the experiments of Lebourdais, mentioned under the head of purified animal charcoal, that several of these principles may be obtained by the sole action of charcoal. For most pharmaceutical operations, and for use as an antidote, animal charcoal must be purified by hydrochloric acid from calcium phosphate and carbonate. (See *Carbo Animalis Purificatus*.) According to Guthe, a German chemist, bone charcoal, without purification, is to be preferred as a decolorizer in all cases in which the calcareous salts exert no injurious effect. Voilé uses animal charcoal as an absorbent in a pill exipient for making creosote and croton oil pills.

CARBO ANIMALIS PURIFICATUS. U. S.

PURIFIED ANIMAL CHARCOAL

(câr'bô ân-î-mă'lis pû-rî-fî-că'tûs)

Charbon animal purifié, *Fr. Cod.*; Gereinigte Knochenkohle, *G.*; Carbone di ossa depurato, *It.*

* "Animal Charcoal, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Hydrochloric Acid, *three hundred grammes* [or 10 ounces av., 255 grains]; Boiling Water, *a sufficient quantity*. Introduce the Animal Charcoal into a capacious vessel, add *two hundred grammes* [or 7 ounces av., 24 grains] of Hydrochloric Acid, and *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Boiling Water. By means of a sand-bath keep the mixture gently boiling during eight hours, adding water occasionally to maintain the original volume. Then add *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Boiling Water, transfer the mixture to a muslin strainer, and, when the liquid has run off, return the Charcoal to the vessel. Add to it *one hundred grammes* [or 3 ounces av., 231 grains] of Hydrochloric Acid and *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Boiling Water, boil for two hours, again add *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Boiling Water, transfer the whole to a plain filter, and when the liquid has passed through, wash the residue with Boiling Water until the washings produce only a faint cloudiness with silver nitrate T.S. Dry the powder in a drying oven, and immediately transfer it to well-stoppered vials." *U. S.*

"Take of Bone Black, in powder, *sixteen ounces* [avoirdupois]; Hydrochloric Acid *ten fluidounces*; Distilled Water *a sufficiency*. Mix the Hydrochloric Acid with a pint of the Water, and add the Bone Black, stirring occasionally. Digest at a moderate temperature for two days, agitating from time to time; collect the undissolved charcoal on a calico filter, and wash with Distilled Water until what passes through gives scarcely any precipitate with nitrate of silver. Dry the charcoal, and then heat it to redness in a closely-covered crucible." *Br.* 1885.

Animal charcoal, as it is made by charring bones, necessarily contains bone phosphate and calcium carbonate, the presence of which does no harm in some decolorizing operations; but in delicate chemical processes these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by diluted hydrochloric acid, which dissolves the phosphate and decomposes the carbonate. According to Stenhouse, aluminized vegetable charcoal is equally efficacious with purified animal charcoal as a decolorizer. (See page 296.)

Properties.—Purified animal charcoal is "a dull black powder, odorless, tasteless, and insoluble in water, alcohol, or other solvents. If 2 Gm. of the powder be ignited at a red heat with

free access of air in a broad, shallow porcelain or platinum dish, it should not leave a residue weighing more than 0.08 Gm., or 4 per cent. of the original weight (limit of *silicates and other fixed inorganic matter*). If 1 Gm. of the powder be boiled with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of water during three minutes, the filtrate should be colorless (evidence of *complete carbonization*)." U. S.

It has been shown by Robert Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through purified animal charcoal, especially when the action is assisted by heat. Weppen finds that a similar effect is produced by it in removing resins from tinctures, tannic acid and bitter principles from astringent and bitter infusions, and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by Lebourdais as an agent for obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and coloring principles. The charcoal, after having been washed and dried, is treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitalin, ilicin, scillitin, columbin, colocynthin, arnicine, strychnine, quinine, and other principles have been obtained by Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) (In relation to the method of Lebourdais, see a paper by J. S. Cobb, in *A. J. P.*, 1851.) A. B. Garrod proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone black has not one-fifth of the power possessed by the purified substance, and vegetable charcoal and lamp-black are nearly or quite useless. The amount of the antidote proposed by Garrod is half an ounce for each grain of a vegetable alkaloid. Alfred Taylor deemed the results of Garrod inconclusive. B. H. Rand made some interesting observations in relation to the antidotal powers of purified animal charcoal, and proved that poisonous doses of the strongest vegetable poisons may be swallowed with impunity if mixed with that substance. (*Med. Exam.*, Sept. 1848.) As an antidote for phosphorus (see *N. Y. M. R.*, 1874, p. 68) its value is very doubtful.

In using animal charcoal for decolorizing active vegetable principles much loss is often incurred by the absorption of those principles by the charcoal.

CARBO LIGNI. U. S., Br.

CHARCOAL

(cār'bō lig'nī)

"Charcoal prepared from soft wood, and very finely powdered. It should be kept in well-

closed vessels." U. S. "The carbonaceous residue of wood charred by exposure to a red heat without access of air." Br.

Carbo Præparatus, Carbo e Ligno, Carbo Vegetabilis; Wood Charcoal, Vegetable Charcoal; Charbon Végétal, Charbon de bois, Fr.; Carbo Ligni Pulveratus, P. G.; Gepulverte Holzkohle, Holzkohle, Präparirte Kohle, G.; Carbone Vegetale, Carbone di legno, It.; Carbon vegetal medicinal, Carbon de lena, Sp.

Preparation on the Large Scale.—Billets of wood are piled in a conical form, and covered with earth and sod to prevent the free access of air, several holes being left at the bottom and one at the top of the pile, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while the hole at the top is closed, and, after the ignition is found to have pervaded the whole pile, those at the bottom are stopped also. The combustion taking place with a smothered flame, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon is left, a portion of it, however, being lost by combustion. Wood, thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in 100 of excellent charcoal; and, at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Aceticum*.) A method of preparing charcoal by subjecting wood to superheated steam has been invented by Violette. When the temperature of steam is 300° C. (572° F.), the wood is converted into a peculiar charcoal, called *red charcoal*, which is intermediate in its qualities between wood and ordinary charcoal. When the temperature is lower, the carbonization is incomplete; when higher, the product is black charcoal. The steam process yields a uniform charcoal for a given temperature, which may be easily regulated, and a product about double that obtained in closed cylinders. Charcoal contains carbon, approximately in proportion to the temperature at which it is formed; varying from 65 per cent. when made at 250° C. (482° F.) to 80 per cent. when made at 400° C. (752° F.). The gaseous matter present, on the other hand, decreases with the temperature of carbonization. Thus, for charcoal made at 300° C. (572° F.), it is one-third of its weight; at 350° C. (662° F.), one-fourth.

E. C. C. Stanford has called attention to a variety of vegetable charcoal, obtained by charring a species of sea weed, *Laminaria digitata*, gathered on the shores of the Hebrides, which, on account of the large proportion of calcium carbonate contained in it (20 per cent.), is unfit for use in refining sugar; it, however, possesses more of the deodorizing and decolorizing power than animal charcoal itself,

which, with the exception referred to, it closely resembles in chemical composition. (P. J., 1867, 186.)

Preparation for Medicinal Use.—Belloc recommends charcoal for this purpose to be obtained from poplar shoots, cut at the time the sap rises, and deprived of their bark. The carbonization should be performed in cast iron vessels at a red-white heat. The product is a light and brilliant charcoal, which must be purified by being macerated for three or four days in water, frequently renewed. It is then dried, powdered, and placed in bottles, which should be well-stoppered. The charcoal most esteemed in Philadelphia for medicinal purposes is that prepared by Dupont, near Wilmington, Delaware, for the manufacture of gunpowder. It is made from young willow shoots of two or three years' growth.

Properties.—Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat. It possesses the remarkable property of absorbing many times its own bulk of certain gases. "A black, odorless, and tasteless powder, free from gritty matter. If 1 Gm. of Charcoal be boiled with a mixture of 3 Cc. of potassium hydroxide T.S. and 5 Cc. of water for several minutes, the filtrate should be colorless or nearly so (evidence of *complete carbonization*)."
U. S. The British Pharmacopœia describes it as "a black powder without taste or odor, free from gritty matter. When burned at a high temperature with free access of air, it should not leave more than $7\frac{1}{2}$ per cent. of ash." When exposed to the air after ignition, charcoal increases rapidly in weight, absorbing from 12 to 14 per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, amounting to 1 or 2 per cent., which is left as ashes when the charcoal is burned. This inorganic material may be removed by digesting the charcoal in diluted hydrochloric acid, and afterwards washing it thoroughly with boiling water.

Uses.—Powdered charcoal is an active absorbent, but otherwise is practically free from medicinal properties. In the past it has been much used in *dyspepsia* with fetid breath, *pyrosis*, *diarrhœa*, and even *constipation*. Its influence upon the bowels, if it has any other than its mechanical action, really tends towards the production of constipation. At one time it was much used as a dressing for ulcers but is at present rarely employed, though the *Cataplasma Carbonis* or charcoal poultice is still occasionally prescribed in Great Britain. Several of its varieties are used as tooth powder. Those generally preferred are the charcoals of the cocoa-nut shell and of bread. It is said that charcoal proves useful in preserving the teeth by absorbing the acid sometimes morbidly present in the mucus of the mouth. The dose of charcoal varies from one to four teaspoonfuls (3.9 to 15.5 Gm.) or more. Daniel

gave it in his case of constipation in doses of a teaspoonful (3.9 Gm.), repeated every half hour. *Charcoal biscuits* have been prepared, containing 15 or 20 per cent. of charcoal in fine powder, while *charcoal lozenges*, either of charcoal alone or associated with bismuth, have been employed with asserted good results in certain forms of gastric disturbances.

For internal use charcoal is preferred by some in the *granular form*. W. Lascelles Scott employs the following method of preparing it. He prefers the wood of the box, willow, or linden, which, after being charred, should be allowed to cool out of contact with air, then boiled for some time in diluted hydrochloric acid, and afterwards, having been thoroughly washed with pure water, in a little weak ammonia. The fragments are again ignited, and then quickly powdered, and passed through a sieve of 80 or 100 apertures to the inch. Nine pounds of this powder are mixed with one pound of pure sugar passed through a 30 sieve, and 4 ounces of gum arabic in impalpable powder. The whole is then moistened with a few ounces of warm distilled water, to which have been added an ounce and a quarter of tincture of benzoïn, and a little mucilage. The mass is now granulated on flat steam pans, in the usual manner, at a temperature of 101.6° to 107.2° C. (215° to 225° F.). When perfectly dry it is sifted, and secured in well-stoppered bottles. (*Chem. News*, 1867, p. 204.)

Stenhouse has devised a process for combining alumina with common vegetable charcoal, forming what he calls *aluminized charcoal*, which is an economical substitute for purified animal charcoal, and equally efficacious as a decolorizer. It is prepared by digesting finely powdered charcoal with sufficient of the solution of aluminum sulphate to give an impregnation of 7.5 per cent. of alumina. The whole is evaporated to dryness, and ignited in a covered Hessian crucible, until the water and acid have been dissipated. Aluminized charcoal is perfectly black, though thoroughly impregnated with anhydrous alumina, and only requires to be carefully pulverized to be ready for use. On similar principles, Stenhouse prepares his *artificial bone black*, by impregnating powdered wood charcoal with 7.5 per cent. of calcium phosphate, by digesting it in a solution of this salt in hydrochloric acid, evaporating to dryness, and igniting in covered vessels. This charcoal decolorizes well, but can be used only for neutral solutions.

Charcoal may act either as an oxidizer or as a deoxidizer, these contrary powers depending upon the temperature of the experiment; at the ordinary temperature, by its porosity, it facilitates atmospheric oxidation of animal matter with which it is placed in contact, while, on the other hand, at a low red heat it deoxidizes or reduces many metallic oxides with the formation of carbon monoxide. The bodies of two dogs having been laid in an open box on a bed of charcoal a few inches deep, and

covered by the same material, were kept by John Turnbull of Glasgow, for six months in his laboratory, without emitting any perceptible effluvia; and when they were examined at the end of this time, scarcely anything remained but the bones. Stenhouse, who relates this experiment, has confirmed it by observations of his own, and believes that the animal matter thus treated undergoes putrefaction, though the products, by their rapid oxidation and absorption, are prevented from contaminating the air. He therefore considers charcoal not to be antiseptic, but the very opposite. It is said that water may be kept sweet at sea by the addition of a little powdered charcoal to each cask.

Dose, five to ten grains (0.32 to 0.65 Gm.).

CARBONEI DISULPHIDUM. *U. S.* (Br.)

CARBON DISULPHIDE [Carbon Bisulphide]

(câr-bô'nê-i di-sûl'phî-dûm)

$CS_2 = 75.57$

"Carbon Disulphide should be kept in partially filled, well-stoppered bottles, or in tin cans, in a cool place, remote from lights or fire." *U. S.* "Carbon Bisulphide, CS_2 , may be prepared by the combination of carbon and sulphur at a high temperature, the product being subsequently condensed and purified." *Br.*

Carbonis Bisulphidum, Br., Carboni Bisulphidum; Carbon Bisulphide; Carbon Sulphide; Sulfure de Carbone, *Fr. Cod.*; Carboneum Sulfuratum, Alcohol Sulfuris, Schwefelkohlenstoff, Kohlensäure, Schwefelalkohol, *G.*; Solfuro di carbonio, *It.*; Sulfuro de carbono, *Sp.*

This compound, corresponding to carbon dioxide (carbonic acid gas), CO_2 , is prepared by the direct combination of carbon and sulphur at a moderate red heat. To effect this, charcoal is heated to redness in a vertical cylinder, while sulphur is admitted through a lateral tubulure near the bottom. As the sulphur melts and vaporizes, it combines with the carbon, and the carbon disulphide formed distills over through a series of condensing tubes, which, while they serve to collect the crude carbon disulphide, allow of the escape of the hydrogen sulphide formed at the same time. The crude product is then rectified, first over a solution of chlorinated lime to break up any hydrogen sulphide gas remaining, and then repeatedly either over mercury, mercuric chloride, anhydrous cupric sulphate, or over a pure fatty oil, which withdraws from it all free sulphur and bad smelling sulphur compounds. The manufacture of carbon disulphide has assumed large proportions. In the works of Deiss at Pantin, near Marseilles, France, 5000 kilogrammes were turned out daily, and their annual production exceeds 1,200,000 kilogrammes.

The most decided improvement in the manufacture of carbon disulphide was made by E.

R. Taylor of Penn Yan, New York, who introduced a patented electrothermal process which can be worked continuously. In large furnaces 41 feet high by 16 feet in diameter an alternating current is applied through carbon electrodes. The metallic sulphur passing over the electrodes is vaporized and rises through the glowing carbon, the carbon disulphide being taken off as vapor through a side connection near the top of the furnace. The impure carbon disulphide is purified by forcing lime water in a fine spray through the disulphide liquor until the water runs out of the tank colorless. The carbon disulphide is finally rectified by steam heat. It is used in the arts for the extraction of oils from different oil seeds, for the extraction of sulphur from some varieties of sulphur ores, for the cleansing of wool and recovering the fat, as a solvent for caoutchouc in the manufacture of india rubber goods, for the extraction of perfumes, and on an enormous scale in France as a remedy against the *phylloxera*. Von Lengyel describes a carbon sulphide having the composition CS_2 . (*Proc. A. Ph. A.*, 1893, 1021.)

Properties.—"A clear, colorless, highly refractive liquid, very diffusive, having a strong, characteristic but not fetid odor, and a sharp, aromatic taste. Specific gravity: 1.256 to 1.257 at 25° C. (77° F.). Soluble in 526 parts of water at 25° C. (77° F.); very soluble in alcohol, ether, chloroform, fixed and volatile oils. Carbon Disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils at 46° to 47° C. (114.8° to 116.6° F.), and when ignited, burns with a bluish-white flame, producing carbon dioxide and sulphur dioxide. It should not affect the color of blue litmus paper moistened with water (absence of sulphur dioxide). A portion evaporated spontaneously in a glass vessel should leave no residue (absence of dissolved sulphur). Lead acetate T.S. agitated with it should not be blackened (absence of hydrogen sulphide)." *U. S.*

Uses.—Carbon disulphide is a powerful poison, but is not used as an internal remedy. According to Delpach, the workmen exposed to the fumes of the disulphide are affected with headache, vertigo, and over-excitement of the nervous system, as evinced by voluble talking, incoherent singing, or immoderate laughter, or sometimes by weeping; and a continuance of the exposure is apt to finally cause a state of cachexia, characterized by general weakness, loss of sexual appetite, dulness of sight and hearing, and impairment of memory. Later writers assert that these phenomena are hysterical, and that what the carbon disulphide does is to produce an hysterical neurosis. (See *Annales de Hygiène*, 1895, xxxiii.) The swallowing by a man of half an ounce of carbon disulphide was followed in half an hour by absolute unconsciousness, very rapid, feeble pulse, slow and stertorous respiration, cold and clammy surface of body, and insensitive con-

junctiva, with mobile pupils. Two hours later, death occurred. The blood was found fluid, but there were no marked lesions of irritation in the gastro-intestinal mucous membrane. (*L. L.*, July 17, 1886.) India rubber workers, by whom the disulphide is largely used, are said to suffer frequently from paralytic symptoms. (*L. L.*, Jan. 1886.)

Externally, the disulphide has been used as a counter-irritant and local anæsthetic. In *enlarged lymphatic glands*, Turnbull has employed it with asserted good success. He applies it by means of a bottle with a proper sized mouth, containing a fluidrachm of the disulphide, imbibed by a piece of sponge. The skin over the gland is first well moistened with water. He employed the vapor also with benefit in deafness, when dependent on want of nervous energy and a deficiency of wax. For this purpose, the bottle containing the disulphide is made with a neck to fit the meatus, and, being applied to the ear, is held there until considerable warmth is produced. The remedy has been used often with very good results, in a similar manner, in *facial* and other *neuralgias* and various local *pains*. It causes a good deal of smarting, but its disagreeable odor is the chief objection to it. Chiandi Bey finds that a solution of carbon disulphide (three parts per thousand) is a most energetic antiseptic, killing microbes and arresting all fermentation; he proposes its use in *zymotic diseases* internally. (*C. R. A. S.*, xcix.) In France the disulphide has been used in *diarrhœa* in 3.5 per cent. solution, of which the dose is two tablespoonfuls (30 Cc.) four or five times a day.

CARDAMOMUM. U. S. (Br.)

CARDAMOM

(cār-dā-mō'mūm)

"The dried nearly ripe fruit of *Elettaria repens* (Sonnerat) Baillon (Fam. *Zingiberaceæ*)." *U. S.* "The dried ripe seeds of *Elettaria Cardamomum*, *Maton*. The seeds should be kept in their pericarps and separated when required for use." *Br.*

Cardamomi Semina, *Br.*; *Cardamomum Minus*, *Cardamomum Malabaricum*; *Malabar Cardamoms*, *Cardamoms*; *Cardamome du Malabar*, *Fr. Cod.*; *Petit Cardamome*, *Fr.*; *Fructus Cardamomi*, *P. G.*; *Malabar Kardamomen*, *Cardamomen*, *Kleine Kardamomen*, *G.*; *Cardamomo minore*, *It.*; *Cardamomo*, *Cardamomo menor*, *Sp.*; *Ebil*, *Arab.*; *Kakelah seggar*, *Pers.*; *Capalaga*, *Malay*; *Gujaratil elachi*, *Hindost.*

The subject of Cardamom has been involved in some confusion and uncertainty, both in its commercial and botanical relations. The name has been applied to the aromatic capsules of various Indian plants belonging to the family of *Zingiberaceæ*. Three varieties have long been

designated by the several titles of the *lesser*, *middle*, and *larger*;—*cardamomum minus*, *medium*, and *majus*; but these terms have been used differently by different writers, so that their precise signification remains doubtful. To Pereira we are mainly indebted for the clearing up of this confusion. It is well known that the *lesser cardamom* of most writers is the variety recognized by the Pharmacopœias and generally kept in the shops. The other varieties, though circulating to a greater or less extent in European and Indian commerce, are little known in this country.¹

¹ *Ceylon Cardamom*.—This has been denominated variously *cardamomum medium*, *cardamomum majus*, and *cardamomum longum*, and is sometimes termed in English commerce *wild cardamom*. It is the *large cardamom* of Guibourt. In the East it is sometimes called *grains of Paradise*; but it is not the product known with us by that name. (See below.) It is derived from a plant cultivated in Candy, in the island of Ceylon, and also growing wild in the forests of the interior, which was designated by Sir James Edward Smith *Elettaria major*, but is now generally acknowledged to be only a variety of the official plant. This plant was described by Pereira in *P. J.*, ii. 388. It is affirmed that the annual product reaches nearly 750,000 pounds. The fruit is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about an inch and a half long and four lines broad, with flat and ribbed sides, tough and coriaceous, brownish or yellow ash-colored, having frequently at one end the long, cylindrical, three-lobed calyx, and at the other the fruit-stalk. It is three-celled, and contains angular, rugged, yellowish-red seeds, of a peculiar fragrant odor and spicy taste. Its effects are analogous to those of the official cardamom.

² *Round Cardamom*.—This is probably the *Amomum* of Dioscorides and the *Amomi uva* of Pliny, and is believed to be the fruit of *Amomum cardamomum*, Willd., growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish white, and sometimes reddish, with brown, angular, cuneiform, shrivelled seeds, which have a spicy camphoraceous flavor. They are sometimes, though rarely, met with connected in their native clusters, constituting the *amomum racemosum*, or *amome en grappe*, of the French. They are similar in medicinal properties to the official, but are seldom used except in the southern parts of Europe.

³ *Java Cardamom*.—The plant producing this variety is supposed to be the *Amomum maximum* of Roxburgh, growing in Java and other Malay islands in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from eight to fifteen lines long, and from four to eight broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown color, and coarse fibrous appearance. When soaked in water, they exhibit as their distinguishing character from nine to thirteen ragged membranous wings along their whole length. The seeds have a feebly aromatic taste and odor. This variety of cardamom affords but a very small proportion of volatile oil, is altogether of inferior quality, and, when imported into London, is usually sent to the continent.

⁴ *Madagascar Cardamom*.—This is the *Cardamomum majus* of Geiger and some others, and is thought to be the fruit of *Amomum angustifolium* of Sonnerat, growing in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, corrugated margin. The seeds have an aromatic flavor analogous to that of official cardamom.

⁵ *Bengal Cardamom*.—The fruit of *Amomum subulatum*, Roxb., sometimes known by the name of *Winged Bengal Cardamom*. *Morung elachi*, or *Buro elachi*, is about an inch in length, obscurely three-sided, ovoid or somewhat obconic, with nine narrow, jagged ridges or wings (best seen after soaking in water) upon its distal end, which terminates in a truncate bristly nipple. The pericarp is coarsely striated, of a deep brown, splitting into three valves, disclosing a three-lobed mass of seeds, 60 to 80 in number.

The official cardamoms are produced solely in India, chiefly in Malabar, Mysore, and adjacent regions. Malabar cardamoms are rather smaller than Mysore cardamoms.

Linnæus confounded, under the name of *Amomum Cardamomum*, two different plants—the genuine, that of Malabar, and another growing in Java. These were separated by Willdenow, who conferred on the former, Sonnerat's title of *Amomum repens*, while he retained the original name for the latter, though not the true cardamom plant. In the tenth volume of the *Linnean Transactions*, 1811, White, a British army surgeon in India, published a very minute description of the Malabar plant, which he had enjoyed frequent opportunities of examining in its native state. From

6.—*Nepaul Cardamom* is produced by an *Amomum* of undetermined species, and resembles the Bengal cardamom, except in having a long tubular calyx on its summit, and in being usually attached to a stalk.

7. *Grains of Paradise. Grana Paradisi.*—Under this name and that of *Guinea grains*, and *Melegueta* or *Mallaguetta pepper*, are found in commerce small seeds of a round or ovate form, often angular, and somewhat coniform, minutely rough, brown externally, white within, of a feebly aromatic odor when rubbed between the fingers, and of a strongly hot and peppery taste. Two kinds of them are known in the English market, one larger, plumper, and more warty, with a short conical projecting tuft of pale fibres on the umbilicus; the other smaller and smoother, and without the fibrous tuft. The latter are varieties more common. It is probable that one of the varieties is produced by *Amomum Grana Paradisi* of Sir J. E. Smith, and the other by Roscoe's *Amomum Melegueta*. (Pereira's *Mat. Med.* 3d ed., p. 1134.) W. F. Daniell, who has published on the *Amoma* of Western Africa, states that the true Mallaguetta pepper is obtained exclusively from varieties of the same species to which belong the *Amomum Granum Paradisi* of Afzelius and the *A. Melegueta* of Roscoe; while the *A. Grana Paradisi* of Sir J. E. Smith is a different plant, and yields from a different product. These grains are imported from Guinea, and other parts of the western coast of Africa. Similar grains are taken to England from Demerara, where they are obtained from a plant cultivated by the negroes, supposed to have been brought from Africa, and believed by Pereira to be the *Amomum Melegueta* of Roscoe. (*Ibid.*, vi. 412.) At the international exhibition of 1862 at London, Geo. B. Wood noticed a specimen of similar grains, under the name of grains of Paradise, sent from the island of Trinidad. Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give artificial strength to spirits, wine, beer, and vinegar. In the same journal (li. 443), Pereira points out seven distinct scitamineous fruits to which the name of grains of Paradise has been applied by different authors. J. C. Thresh made a proximate analysis of the seeds, and found volatile oil, resin, tannin, starch, albuminoids, and an active principle in the form of a straw-colored, and an active principle in the form of a straw-colored, viscid, odorless fluid, pungent, but not so hot as capsaicin. (P. J. 1884, p. 297.) Fredk. Schwartz found in the seeds a reddish-brown acrid resin, and an oil having a burning aromatic taste, upon which the virtues probably depend. (A. J. P., 1886, 118; consult also Hanausek's researches on grains of Paradise in *Chem. Ztg.*, 1893, 1765.)

Bastard Cardamom, the seeds of *Amomum Xanthoides*, Wall., resembles true cardamom in appearance, but is of a dirty green color, and has a very biting camphor-like taste. B. Niederstadt gives the following as the results of analysis of the true (hulled) seed and of the bastard cardamom:

	True.	Bastard.
Water.....	15.25	15.50
Ether soluble extract.....	5.10	4.04
Ash.....	6.55	7.50
Starch and sugar.....	28.84	24.00
Cellular tissue, nitrogenous matters and extractive.....	44.26	48.96

A cardamom from East Africa, with a flavor resembling that of official cardamom and of the Korarima cardamom, is said to have been seen in the London market, but apparently has not been identified,

this description Maton inferred that the plant, according to Roscoe's arrangement of the Scitamineaceæ, could not be considered an *Amomum*; and as he was unable to attach it to any other known genus, he proposed to construct a new one, with the name of *Elettaria*, derived from *ellettari* or *elatari*, the Malabar name of this drug. Sir James Smith afterwards suggested the propriety of naming the new genus *Matonia*, in honor of Maton; and the latter title, having been adopted by Roscoe, obtained a place in former editions of the London and U. S. Pharmacopœias. The celebrated Roxburgh described the Malabar cardamom plant as an *Alpinia*, with the specific name *Cardamomum*. As doubts were entertained of the necessity for the new genus proposed by Maton, Roxburgh was followed in the London and U. S. Pharmacopœias, and the fruit was referred to *Alpinia Cardamomum*. This decision, however, was revised in the later editions of the U. S. and British Pharmacopœias. Roscoe arranged it with the abandoned genus *Renealmia* of Linnæus, which he restored.

Elettaria repens (Sonnerat), Baillon; *E. Cardamomum*, Maton; B. & T. 267.—*Alpinia Cardamomum*, Roxburgh.—*Amomum repens*, Sonnerat; Willd., *Sp. Plant.* i. 9.—*Renealmia Cardamomum*, Roscoe.—*Matonia Cardamomum*, Smith. Figured in *Linn. Trans.*, x. 243, and Carson's *Illustr. of Med. Bot.*, ii. 55.—The cardamom plant has a tuberous horizontal root or rhizome, furnished with numerous fibres, and sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate sheathing leaves. These are from nine inches to two feet long, from one to five inches broad, elliptical-lanceolate, pointed, entire, smooth and dark green on the upper surface, glossy and pale sea-green beneath, with strong midribs, and short footstalks. The flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in a panicle. The calyx is monophyllous, tubular, and toothed at the margin; the corolla monophyllous and funnel-shaped, with the inferior border unilabiate, three-lobed, and spurred at the base. The fruit is a three-celled capsule, containing many seeds; during drying it is said to lose three-fourths of its weight.

This valuable plant is a native of the mountains of Malabar, where it springs up spontaneously in the forests after the removal of the undergrowth, and is very extensively cultivated by the natives. For a detailed account of culture, see A. J. P., 1877, 605; also P. J., 1888. Cardamoms have also been cultivated to some extent in tropical America. The plant begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit-stems, dried over a gentle fire or by sun-heat, and separated by rubbing with the hands from the footstalks and adhering calyces. J. W. Mollison describes

the method of washing and curing cardamoms employed in the Bombay Presidency, India. The washing and manipulation is performed by women, and water from special wells is employed. The cardamoms are first washed in earthenware vessels containing a mixture of the well water and pounded soap nut and a species of acacia, in the proportion of two pounds of the former to a quarter pound of the latter. About ten pounds of cardamoms are treated at one time. Two women stir them vigorously in the mixture for about one minute and then allow them to rest about an equal length of time, and again stir for another minute. A thick lather results. This completes the first washing, after which the cardamoms are baled out by hand into a basket where they are allowed to drain for a few seconds, and then subjected to a second washing similar to the first except that the mixture contains less of the soap nut preparation and an additional quantity of soap solution. They are then thrown upon a mat and sprinkled with water from the special well at intervals of a half hour, until the next morning, when they are spread upon the roof of a house and allowed to dry for four or five hours. After nipping off the short stalk, an operation performed with a large pair of shears by women who are often very expert, the cardamoms are sorted, only the most plump fruits being prepared for the foreign market. Besides bleaching by this process, cardamoms are also subjected to starching in India. The starched product has a whiter appearance than the bleached cardamoms. The starch is prepared by pounding together rice, wheat, country soap and buttermilk. The paste is diluted with water and sprinkled over the cardamoms as they are rubbed by hand. (*B. C. D.*, 1904, see also *Ph. Era*, 1904, 137.)

Thus prepared, they are ovate-oblong, from three to ten lines long, from two to four thick, three-sided with rounded angles, obtusely pointed at both ends, longitudinally wrinkled, and of a yellowish-white color. The seeds which they contain are small, angular, irregular, rough as if embossed upon their surface, of a brown color, easily reduced to powder, and thus separable from the capsular covering, which, though slightly aromatic, is much less so than the seeds, and should be rejected when the medicine is administered. The seeds constitute about 74 parts per cent. by weight. According to Pereira, three varieties are distinguished in commerce: 1, the *shorts*, from three to six lines long, from two or three broad, browner and more coarsely ribbed and more highly esteemed than the others; 2, the *long-longs*, from seven lines to an inch in length by two or three lines in breadth, elongated, and somewhat acuminate; and 3, the *short-longs*, which are somewhat shorter and less pointed than the second variety. The odor of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic. "Oblong-ovoid, obtusely triangular in transverse section, from 10 to 20 Mm. long, slightly

beaked at the apex, rounded to truncate at the base; three-celled and with central placentæ; pericarp thin, leathery, nearly tasteless, and of a pale yellow color; seeds 15 to 18 in number, about 4 Mm. long, oblong-ovoid and irregularly angular, reddish-brown, enclosed in a thin, membranous aril; odor and taste strongly and agreeably aromatic. Ash not more than 4 per cent. The seeds alone contain active and valuable constituents." *U. S.* "Incinerated they should not yield more than 4 per cent. of ash." *Br.* Cardamom yields its virtues to water and alcohol, but more readily to the latter. The seeds contain 4.6 per cent. of volatile oil, 10.4 of fixed oil, 2.5 of a salt of potassium mixed with a coloring principle, 3.0 of starch, 1.8 of nitrogenous mucilage, 0.4 of yellow coloring matter, and 77.3 of ligneous fibre. (Trommsdorff.) The volatile oil is colorless, of an agreeable and very penetrating odor, and of a strong aromatic, burning, camphorous, and bitterish taste. It is dextrogyrate, and consists essentially of a terpene, $C_{10}H_{16}$, with small quantities of formic and acetic acids. From old specimens of oil Dumas and Peligot claim to have separated crystals of *terpene hydrate*, $C_{10}H_{16}O_2 + H_2O$, while Flückiger has obtained a crystalline deposit from Ceylon oil which he considers identical with common camphor. Weber (*Ann. Ch. Ph.*, 238, 98) speaks of finding a small amount of a crystalline non-volatile compound which fuses at 60° to 61° C. Schimmel & Co. published in their semi-annual reports for April and October, 1897, some results of investigation of several varieties of cardamom oil. The terpenes of Ceylon oil they state to be *terpinene* and *dipentene*; both Ceylon and Bengal cardamom contain *cineol*, $C_{10}H_{18}O$; Malabar cardamom yields *terpineol* as well as *cineol*, while Siam cardamom yields a crystalline sediment composed of borneol and camphor in approximately equal proportions. The sp. gr. of the oil is between 0.92 and 0.94. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odor and taste. If ether be made to percolate through the powdered seeds, and the liquor obtained be deprived of the ether, a light greenish-brown fluid remains, consisting almost exclusively of the volatile and fixed oils. It has the odor of cardamom, and keeps better than the oil obtained by distillation. (*A. J. P.*, xxi. 116.) The oil of cardamom of commerce is often factitious, being composed of several cheap volatile oils, oils of cajuput, nutmeg, and others being used. Schimmel & Co. announced in 1901 that they no longer distilled the oil from the fruit of *Elettaria Cardamomum*, but from the seeds of another species; this oil makes a clear solution with three parts by volume of 70 per cent. alcohol. (*Schim. Rep.*, 1901, 14.) The seeds should be powdered only when wanted for use, as they retain their aromatic properties best while in the capsule.

Cardamoms are sometimes adulterated; G. W. Kennedy reported nearly 4 per cent. of orange

seeds and unroasted grains of coffee mixed with the cardamoms. (*A. J. P.*, 1872.) Solstein (1892) found that pure powdered cardamom yields 8.36 per cent. of ash; three commercial samples of powdered cardamom that he examined contained sodium carbonate.

Uses.—Cardamom is a grateful aromatic, not strongly heating and stimulating, and useful chiefly as an adjuvant. Throughout the East Indies it is largely consumed as a condiment. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Dose, fifteen to thirty grains (1 to 2 Gm.).

CARUM. U. S. (Br.)

CARAWAY

(cā'rūm)

"The dried fruit of *Carum Carvi* Linné (*Fam. Umbelliferae*)."
U. S. "The dried fruit of *Carum Carvi*, Linn." *Br.*

Carui Fructus, *Br.*; Caraway Fruit; Carvies, Cumín des Prés, Carvi, *Fr. Od.*; Fructus Carvi, *P. G.*; Gemeiner Kümmel, Kümmel, Garbe, *G.*

Carum Carvi, Willd., *Sp. Plant.*, i. 1470; *B. & T.* 121.—This plant is biennial and umbelliferous, with a spindle-shaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and in erect terminal umbels, with an involucre, consisting sometimes of three or four bracts, sometimes of one only, and are destitute of partial involucre.

The caraway plant is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced into this country. The flowers appear in May and June, and the seeds, which are not perfected until the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food in Northern Europe. The seeds are the part used in medicine. They are collected by cutting down the plant, and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American seeds are usually rather smaller than the German. Under the name of *Ajowan*, the fruits of the *Carum Ajowan*, Benth & Hooker (*Ammi copticum*, L.), are largely used in India. They are $\frac{1}{16}$ to $\frac{1}{8}$ of an inch long, and resemble the fruits of common parsley, but are distinguished by their odor, and by their surface being very rough from numerous very minute tubercles. They contain about 4 per cent. of a volatile

oil, which has the odor of the oil of thyme, and contains thymol; it may be used as an aromatic carminative. (See *B. M. J.*, June 6, 1885.) For a description of the oil of *ajowan* see *Schim. Rep.*, 1903, 78.

Caraway seeds (half-fruits) are about two lines in length, slightly curved, with five longitudinal ridges, which are of a light yellowish color, while the intervening spaces are dark brown. "About 4 or 5 Mm. long, oblong, laterally compressed, usually separated into the two mericarps, which are curved, tapering toward each end, dark brown, with five yellowish, filiform ribs, and with six oil-tubes; seed plane upon the face, nearly equilaterally pentagonal in transverse section; odor and taste agreeably aromatic; ash not more than 8 percent." *U. S.* "When incinerated the Fruit should not yield more than 8 per cent. of ash." *Br.* They have an agreeable aromatic odor, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. (See *Oleum Cari*.) The residue is insipid. They yield their virtues readily to alcohol and more slowly to water.

"Drawn caraway seeds," a term applied to such as have been recovered from the still residue after obtaining the volatile oil, are used to adulterate caraway; the exhausted "seeds" are much darker in color than the genuine. (*P. J.*, 1896, 150.)

Uses.—Caraway is a pleasant stomachic and carminative, occasionally used in *flatulent colic*, and as an adjuvant or corrective of other medicines. The dose in substance is from 15 to 30 grains (1 to 2 Gm.). An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See *Oleum Cari*.) Three and a half ounces of the oil of caraway caused violent vomiting and abdominal pain, with loss of consciousness, ending, however, in recovery. The urine contained both acetone and albumin. (*Cb. I. M.*, xxii. 1902.) In culinary operations the seeds are added to cakes, to which they communicate an agreeable flavor, while they stimulate the digestive organs.

Dose, fifteen to thirty grains (1 to 2 Gm.).

Eugenia aromatica (L.), O. Kuntze; *E. caryophyllata*, Willd., *Sp. Plant.* ii. 965; B. & T. 112.—*Caryophyllus aromaticus*, L., *Sp. Plant.*, 735; De Cand., *Prodrom.*, iii. 262; Carson, *Illust. of Med. Bot.*, i. 43, pl. 37.—This small tree is one of the most elegant of those inhabiting the islands of India. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth, grayish bark. The leaves are about four inches in length by two in breadth, obovate-oblong, acuminate at both ends, entire, sinuated, with many parallel veins on each side of the midrib, supported on long footstalks, and opposite. They have a firm consistence and a shining green color, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odor.

The natural geographical range of the clove is extremely limited, being confined to the Molucca or, as they were one time called, Clove Islands. According to Flückiger, cloves were known in Western Europe as early as the sixth century, long before the discovery of the Moluccas by the Portuguese. After the conquest of the Molucca Islands by the Dutch, the monopolizing policy of that commercial people led them to extirpate the trees in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding their jealous vigilance, a French governor of the Isles of France and Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas and introducing them into the colonies under his control. Five years afterwards the clove-tree was introduced into Cayenne and the West Indies, in 1803 into Sumatra, and in 1818 into Zanzibar. At present the spice is cultivated both in the West and East Indies, in tropical Africa, and in Brazil.

The unexpanded flower buds are the part of the plant employed under the ordinary name of cloves.¹ They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are at first white, then become green, and then bright red, when they must be at once collected, which is done by hand picking, or by beating the trees with bamboos and catching the falling buds. In the Moluccas they are said to be sometimes immersed in boiling water and afterwards exposed to smoke and artificial heat before being spread out in the sun. In Zanzibar, Cayenne, and the West Indies they are dried simply by solar heat.

Although it is stated that as early as 266 B. C., during the reign of the Han dynasty,

the Chinese court officers were accustomed to hold cloves in their mouths before addressing the sovereign, that their breath might have an agreeable odor, the spice seems to have been first introduced into Europe in the fourth century, and became a great source of wealth to the enterprising merchants of mediæval Venice, who obtained it from the Arabians. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese, but was subsequently wrested from them by the Dutch, by whom it was long monopolized. The United States derive much of their supply from the West Indies and Guiana; but the great sources of cloves have been recently the islands of Zanzibar and Pemba, on the east coast of Africa. In 1872 the clove orchards in Zanzibar were nearly destroyed by a hurricane, but they have been replanted.² In commerce the varieties of cloves are known by the names of the localities of their growth, and so closely resemble one another as to be distinguished only by experts. The *Penang cloves* have been especially esteemed. The *Bencoolen cloves* from Sumatra are by many druggists deemed equal to them. The Amboyna and Molucca cloves are stated to be thicker, darker, heavier, more oily, and more highly aromatic than those cultivated elsewhere. Formerly cloves were frequently adulterated, but the comparatively low price of later times has discouraged this fraud. (See Kraemer, *Proc. A. Ph. A.*, 1894, 159.)

Properties.—Cloves resemble in shape a nail with a round head with four spreading points beneath it. "About 15 Mm. long, brownish-black, consisting of a stem-like, solid calyx-tube, obscurely four-angled and granular roughened, terminated by four teeth, and surmounted by a globular head, consisting of four petals, which cover numerous curved stamens and one style; odor strongly aromatic; taste pungent and aromatic, followed by slight numbness. Cloves should not float in a horizontal position on water. The powder contains few or no starch grains or stone cells. Ash not more than 8 percent." *U. S.* "Incinerated they should not yield more than 7 per cent. of ash." *Br.* Their color is externally deep brown, internally reddish; their odor strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves are large, heavy, brittle, and exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and odor, they are inferior. Those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine. In powdered cloves this fraud appears to be extensively practised, and its detection is almost impossible.

Trommsdorf obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin, 130 of gum, 60 of resin, 280 of vegetable

² For detailed information as to method of growth, see *P. J.*, June, 1890.

¹ The stems of the flowers also enter commerce. They possess the odor and taste of the cloves, and, as they are worth only about one-fifth the price of the cloves and are said nearly to equal them in strength, they are largely used in the manufacture of ground cloves as well as of oil of cloves. In France they are generally known by the name of *griffes de girofle*.

fibre, and 180 of water. Wm. L. Peabody (1895) found the percentage of tannin in cloves to range from 10 to 13 per cent., and that it has the same chemical composition as gallo-tannic acid. Lodibert afterwards discovered a fixed oil, aromatic and of a green color, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or odor, soluble in ether and boiling alcohol, and exhibiting neither alkaline nor acid reaction. This substance, called by Bonastre *caryophyllin*, was found in the cloves of the Moluccas, of Bourbon, and of Barbados, but not in those of Cayenne, from which, however, it has since been procured. To obtain it, the ethereal extract of cloves is treated with water, and the white substance thrown down is separated by filtration, and treated repeatedly with ammonia to deprive it of impurities. The most recent determination of its formula by Mylius (*Ber. d. Chem. Ges.*, 1873, p. 1053) makes it $C_{20}H_{32}O_2$. Theod. Martius obtains it cheaply by exposing cloves, previously deprived as far as possible of oil by distillation with water, to distillation at a higher temperature, redistilling the brown liquid obtained until the distillate nearly ceases to have the taste or odor of cloves, and then purifying the residue by washing with water, and treating it with boiling alcohol and animal charcoal repeatedly, until the caryophyllin, which is deposited by the alcohol on cooling, is perfectly white. (See *A. J. P.*, xxxii. 65.) Dumas has discovered another crystalline principle, which forms in the water distilled from cloves, and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in becoming red when touched with nitric acid. Bonastre proposed for it the name of *eugenin*. (*J. P. C.*, xx. 565.) It has the formula $C_{10}H_{12}O_2$, and is isomeric with eugenol or eugenic acid, a constituent of oil of cloves. Water extracts the odor of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid if deprived of the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. *Caryophyllin acid*, $C_{20}H_{32}O_4$, is obtained by gradually adding caryophyllin to fuming nitric acid, kept cool by immersing the vessel in water until crystals begin to separate; these are purified by dissolving them in ammonia, precipitating with hydrochloric acid, and redissolving in alcohol and crystallizing. For an account of the oil, see *Oleum Caryophylli*. The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of ferric chloride, facts of some interest, as morphine gives the same reactions.

Uses.—Cloves are among the most stimulant of the aromatics, but, like others of this class,

act less upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve *nausea* and *vomiting*, correct *flatulence*, and excite *languid digestion*; but their chief use is to assist or modify the action of other medicines. They enter into several official preparations.

The French Codex directs a *tincture of cloves* to be prepared by digesting for ten days, and afterwards filtering, a mixture of three ounces of powdered cloves and sixteen of 80 per cent. alcohol.

Dose, in substance, from five to ten grains (0.32 to 0.65 Gm.).

CASCARILLA. Br.

CASCARILLA

(cās-ca-ril'la)

"The dried bark of *Croton Eluteria*, *J. J. Bennett.*" *Br.*

Cascarilla Cortex, *Br.* (1885), *Cascarilla Bark*, *Sweetwood Bark*; *Cascarilla officinale*, *Fr. Cod.*; *Cortex Eluteria*, *Cortex Thuris*; *Chacrilla*, *Ecorce éleuthérienne*, *Cascarille*, *Fr.*; *Cortex Cascarillæ*, *P. G.*; *Cascarillrinde*, *Cascarilla*, *Kaskarillrinde*, *G.*; *Cascarilla*, *Cascariglia*, *It.*; *Chacarrilla*, *Quina aromatica*, *Sp.*

There has been much confusion in relation to the different species of *Croton* growing in the West Indies, and as to which of them the *Cascarilla* of commerce is to be ascribed. At present, however, it is generally admitted that this bark,¹ which is brought exclusively from the Bahama Islands, is the product of *Croton Eluteria*; and, though it is probable that the proper *C. Cascarilla* may at one time have yielded a portion of its bark to commerce, at present little or none is derived from that species. The London College committed the error, which it afterwards corrected, of recognizing *C. Cascarilla* of Don as the source of it. This botanist mistook the *Copalchi* bark of Mexico, which is produced by *Croton Pseudochina* of Schiede, and somewhat resembles *cascarilla*, for the genuine bark, and hence proposed to transfer the specific name of *Cascarilla* to the Mexican plant.²

¹ Under the name of "*cascarilla*," also "*Quina morada*," the bark of the *Pogonopus febrifugus* is said to be used in the Argentine Republic as a substitute for the true cinchona bark. There has been separated from it a blue fluorescent substance, *moradin*, and an alkaloid, *moradine*. (*P. J.*, xx. 854.)

² *Copalchi* bark has been mistaken not only for *cascarilla*, but also for a variety of cinchona. Portions of it, having been taken to Europe, attracted the attention both of pharmacologists and physicians. Two kinds were noticed: one, in small slender quills, of an ash color, bearing some resemblance to a variety of pale cinchona, but having the flavor of *cascarilla*, and burning with a similar odor; the other in larger

Croton Eluteria, Bennett, *Journ. of the Linn. Soc.*, iv. 29; Daniell, *P. J.*, 2d ser., iv. 145, figured at p. 150; *B. & T.* 238.—*Clusia Eluteria*, Woody., *Med. Bot.*, 3d ed., iv. 633, t. 223. As described by W. F. Daniell, who resided in the Bahama Islands, this, though commonly a shrub from three to five feet high, sometimes appears in the form of a small tree with a stem from four to eight inches in diameter.² The stem is straight, and marked at intervals with white or grayish stains. The leaves are petiolate, from two to three inches in length by an inch or more in breadth, often somewhat cordate at the base, obtusely acuminate, pale or grayish green above, and densely covered beneath with shining silvery scales, appearing white at a distance. They are smaller and narrower in the plants of arborescent growth. The flowers, which have a delicious odor, are monœcious, small, white, petiolate, and closely set in simple terminal or axillary spikes. The shrub is a native of the Bahamas, scarce at present in the island of New Providence, but still abundant in Andros, Long, and Eleutheria islands, from the latter of which is derived its botanical title. Daniell calls the plant *sweet-wood*. The name of *sea-side balsam* belongs to another species, *C. balsamiferum* of Linnæus, which grows in the Bahamas and other West India islands, and owes its name to the exudation of a balsamic juice from its young branches when wounded.

Croton Cascarilla, Bennett, *Journ. of the Linn. Soc.*, iv. 30.—*Clusia Cascarilla*, Linn., *Sp. Plant.*, ed. 1, 1042.—*Ricinoides eleagnifolia*, Catesby, *Hist. Carolin.*, ii. t. 46.—As described by Daniell, this is a shrub of from four to six feet, much branched, with a pale grayish-green stem, without the white stains of the former species. The leaves are petiolate, long,

narrow, lanceolate, tapering towards each end, pointed, with flat or somewhat undular margins, above smooth and green, beneath pale and very hairy. The flowers are monœcious, in simple terminal spikes, with small white petals tinged with yellow. They are very fragrant. The plant is a native of the Bahamas, and is said also to grow in Hayti. In the Bahamas it is much scarcer than formerly, and is said by Daniell to yield at present none of the cascarilla of commerce, although much was formerly derived from it. This species seems to have been confounded by some with *Croton lineare* of Jacquin, which grows in the Bahamas and most of the West India islands, where it is known by the name of *wild rosemary*, owing probably in part to its fragrant odor, but still more to its narrow linear leaves with reflected margins.

Cascarilla is brought to this market from the West Indies, and chiefly, as we have been informed, from the Bahamas. It comes in bags or casks. We have observed it in commerce in two forms, so distinct as to merit the titles of varieties. In one, the bark is in rolled pieces of every size, from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark brown surface, while the inner surface has a chocolate color, and the fracture is a reddish brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces, not more than an inch or two in length, very thin, without the white epidermis, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fibre attached to their inner surface, and appearing precisely as if shaved by a knife from the stem or branches. Whether these two varieties are derived from distinct species, or differ only because of the mode of collection, it is difficult to determine. A. W. Southall describes a bark (believed to belong to the genus *Croton*, and obtained from Colombia) in *P. J.*, 1894, 574. "In quills or curved pieces about 2 Mm. thick, having a grayish, somewhat fissured, easily detached, corky layer, more or less coated with a white lichen, the uncoated surface being dull brown, and the inner surface smooth. It breaks with a short fracture, having a resinous and radially striate appearance. When burned, it emits a strong, aromatic, somewhat musk-like odor; its taste is warm and very bitter." *U. S.* 1890. "Fracture short, and resinous; the transverse section exhibits under a lens dark reddish-brown bast traversed by thin whitish medullary rays, but no groups of sclerenchymatous cells." *Br.*

Properties.—Cascarilla has an aromatic odor, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, break-
